Infirmary, fee £2 2s. 4. Pathological Bacteriology: Dr. T. Shennan, Surgeon's Hall, fee £2 2s. 5. Dermatology: Drs. Allan Jamieson and Norman Walker, fee £3 3s.; Dr. Stewart Stirling, Skin Dispensary, Lauriston Place, fee £1 1s. 6. Diseases of Children: Sick Children's Hospital, Dr. John Thomson; minor surgical diseases of children, Mr. H. J. Stiles, fee £2 2s. 7. Chest diseases: Dr. R. W. Philip, Victoria Hospital and Dispensary, fee £2 2s. 8. Gynaecology: Dr. Brewis, fee £2 2s. 9. The Demonstrations on Modern Gastric Methods, by Dr. A. Lockhart Gillespie, fee £2 2s., available at any time during the year on the request of a sufficient number of post-graduates. All these courses are of short duration, varying in length from three to six weeks. In addition to these, arrangements have been made whereby a special series of short courses, including many of those above, are given simultaneously at a time to be afterwards fixed upon and advertised. The additional subjects dealt with include—Medical and Surgical Anatomy, Electricity in medicine, by Dr. Dawson Turner; Infectious Diseases, by Dr. C. Ker; Practical Sanitation, Dr. H. Littlejohn; Operative Surgery, &c. The usual fee for each class is £2 2s. The Honorary Secretary, Post-Graduate courses, Surgeons' Hall, will supply a full syllabus on application.

In Glasgow, special courses in ear diseases are held in November and May at Anderson's College, and post-graduate courses in pathology and bacteriology at the University from September 13th to October 12th, 1898. Fee for either, £3 3s.; for both, £5 5s., with 5s. matriculation fee.

THE OPENING OF THE MEDICAL SCHOOLS, LONDON.

Charing Cross Hospital Medical School—Monday, Oct. 2nd. Introductory Address by Dr. Mitchell Bruce.
Dental Hospital of London—Monday, Oct. 2nd.
Guy's Hospital Medical School—Monday, Oct. 2nd.
King's College London, Medical Faculty—Monday, Oct. 2nd.
London Hospital Medical College—Monday, Oct. 2nd.
Middlesex Hospital Medical School—Monday, Oct. 2nd. Introductory Address by Mr. J. Murray, F.R.C.S.
Royal Free Hospital School of Medicine for Women—Monday, Oct. 2nd. Introductory Address by the Dean, Mrs. Garrett Anderson, M.D.
St. Bartholomew's Hospital and College—Monday, Oct. 2nd.
St. George's Hospital Medical School—Monday, Oct. 2nd, at 4 p.m. Introductory Address by Dr. Howship Dickinson.
St. Mary's Hospital Medical School—Monday, Oct. 2nd, at 3 p.m. Introductory Address by H. G. Plimmer, Esq.
St. Thomas's Hospital Medical College—Tuesday, Oct. 3rd, at 3 p.m. Prizes distributed by Prof. T. C. Allbutt, M.D., F.R.S.
University College Medical School—Monday, Oct. 2nd, at 4 p.m. Introductory Address by Dr. G. F. Blacker.
Westminster Hospital Medical School—Monday, Oct. 2nd, at 4 p.m.

PROVINCES.

Birmingham, Mason College—Monday, Oct. 2nd.
Bristol, University College—October.
Cardiff, University School of Medicine—Monday, Oct. 2nd. Introductory Address on the evening of Oct. 6th, by Professor A. W. Hughes.
Durham University School of Medicine—Monday, Oct. 2nd.
Liverpool, University College—Tuesday, Oct. 3rd.
Manchester, Owens College—Monday, Oct. 2nd.
Sheffield, University College—Monday, Oct. 2nd. Introductory Address by Sir J. Crichton Browne, LL.D., M.D., F.R.S.
The Yorkshire College—Monday, Oct. 2nd. Introductory Address, followed by the Distribution of Prizes, at 5 p.m., by Dr. Byrom Bramwell.

IRELAND.

Adelaide Medical and Surgical Hospitals, Dublin.
Catholic University Medical School, Dublin—Nov. 2nd.
City of Dublin Hospital—Oct. 2nd—Monday, Oct. 2nd.
Dublin University—Oct. 2nd.
Meath Hospital—Monday, Oct. 2nd, at 4.30 p.m. Introductory Address by Dr. John William Moore.
Mercer's Hospital, Monday—Oct. 2nd.
St. Vincent's Hospital—Tuesday, Oct. 3rd. Dr. Tobin, 4.30 p.m.
Queen's College, Cork—Monday, Oct. 2nd.
Royal Col. of Surgeons, Dublin Schools of Surgery—Monday, Oct. 2nd.
Trinity College School of Physics, Dublin, Dissecting Rooms, &c.
First week in October: lectures begin first week November.

SCOTLAND.

Aberdeen University—Monday, Oct. 16th.
Dundee University College—Wednesday, Oct. 12th.
Edinburgh University—Tuesday, Oct. 17th.
Edinburgh School of Medicine, Rooms, and Laboratories, Monday, Oct. 2nd.
Edinburgh School of Medicine for Women—Tuesday, Oct. 17th.
Glasgow, Anderson's College Medical School—Thursday, Oct. 19th.
Glasgow, Queen Margaret College School of Medicine for Women—Oct. 19th.
Glasgow University—Thursday, Oct. 5th.
Glasgow, St. Mungo's College—Thursday, Oct. 19th.
Glasgow Royal Infirmary—Thursday, Oct. 19th.
Royal Colleges, Edinburgh—Tuesday, Oct. 17th.
St. Andrew's University—Wednesday, Oct. 11th.

Notes on Current Topics.

The Question of Education.

THERE are many interested at this time of the year in the question how they can best prepare their sons for that business in life for which they are, in their opinion, best qualified, or are most likely to succeed in. School is over, and now certain lines of study must be selected which will gradually lead to qualifying for a profession or a business, by which an independence will be secured. The question we are considering is whether a boy, before he leaves school, can prepare himself for the line of study required by the Medical Council after he has registered, and before he can enter at a medical school. There are certain subjects which are not specially medical, such as chemistry, botany, and physics, and which are now taught at most of our public schools. Whether a boy shall acquire any knowledge of them or not while at school requires consideration. There is no doubt but that it gives a boy a great advantage, if he intends to register, to have acquired some knowledge of chemistry, biology, and physics before he leaves school, and there is no doubt but that every encouragement is being given to our public schools to provide tuition in science subjects. If our medical schools are relieved of these subjects, and those who enter them can at once begin to attend lectures on anatomy and physiology, it must greatly simplify matters. But we think it would be well if more care were taken at our medical schools to avoid a great deal of the useless detail which is taught in anatomy and physiology. It ought to be clearly recognised that these subjects should always be studied with a practical end in view. They are certainly sciences, but in the teaching of a science it is a mere waste of time to enter into minute details which are of no practical use to students. How much of the anatomy of the bones and other parts in our text books is really of use in the practice of medicine and surgery? For examination purposes they have to be learnt, but it would be well if examiners were prevented from requiring a student to cram for examination, and those who teach anatomy and physiology ought to be, not professors, but surgeons and physicians. The education of our medical students as at present carried out is far more a question of preparing them for examinations than of teaching them what they ought to know; and there is no doubt but that the teaching at our hospitals has sadly degenerated, and that a system of cramming has grown up which urgently calls for reform. The operating room ought to be the chief source of knowledge of surgery for students, but very little, if any, use is made of it for this purpose. The real reason of this is that there is no inducement for the surgeons at hospitals to give any time to teaching, for the good reason that they are not paid well enough to make it worth their while to do so. All that the student has to do is to get his lectures signed up, and as to learning anything from lectures which will help him in examinations he generally feels that

the time would be far better spent in reading than in listening to a lecturer. We will not say more on this subject except that we think it would be well for the managers of our medical schools to set about the reform of the present state of things.

Secret Commissions and the Medical Profession.

CONSIDERABLE discussion has taken place in the daily press on the indictment framed by Sir Edward Fry concerning the alleged participation of members of the medical profession in the practice of receiving secret commissions. As might be expected, no further light has been thrown on the allegation which rests upon the unsupported assertions of two or three irresponsible witnesses. The ventilation of this unsavoury topic will, however, have rendered one signal service, for it will, we trust, have made it perfectly clear that even if a few individual members of the profession have really stooped to the practice it is heartily condemned and religiously shunned by the profession as a whole. The publicity given to the matter, moreover, may give rise to searchings of conscience and thus reinforce the abhorrence which is unquestionably felt by the vast majority of medical men towards such a degrading means of making money. It is within the experience of most medical practitioners that opportunities of the kind are very frequently offered but, as far as our experience goes, such offers are invariably regarded in the light of personal insults and recoil upon those who have had the temerity to make them. The matter is not one of which the General Medical Council has so far taken recognizance, but it has never been asked to do so, and in any event delinquencies of this kind are obviously very difficult to bring home to the offender. It would not be amiss, by way of reassuring public opinion, if the Council took an early opportunity of publicly stigmatising the taking of secret commissions as "infamous conduct in a professional respect." In so doing it would only voice the unanimous feeling in the ranks of the medical profession, and the pronouncement would go far to correct the impression which the mere mention of the contingency cannot fail to have left in the minds of a certain section of the public.

The Malarial Mosquito.

THE achievements of the little band of observers sent to Africa by the Liverpool School of Tropical Diseases are being well advertised in the lay Press, a course which is sufficiently at variance with custom to excite some diffidence in expressing approval thereof. We have had too much experience of these interim reports in the past for them to carry conviction, and we prefer to postpone judgment in respect of the results until the subject has been duly brought forward by the observers in medical circles and subjected to the disintegrating force of hostile criticism. Even if, as announced, the parasite of malaria has been discovered in the body of the anopheles, that fact does not clear up the mystery surrounding the etiology of the disease because, as

has been pointed out, malaria exists in places where the mosquito is unknown. Then, again, though the discovery, if authenticated, possesses considerable scientific interest, we are but on the threshold of the preventive treatment of malaria. If, for instance, it were shown that measles was communicated by the bite of the flea, the extinction of the genus flea would not be easy of accomplishment, and the problem of the extinction of the mosquito is a problem of even greater magnitude. The attentive study of the natural history of the mosquito will doubtless enable us to follow it through the various phases of its evolution, but the uncontrollable facilities which nature provides for its multiplication in tropical climes are likely to defy our puny attempts at extermination. Our object in making these remarks is assuredly not to decry the invaluable work which is being done all over the world in the investigation of the causes and prevention of malarial disease, but rather to present these recent discoveries in their true light. It is greatly to be hoped that the Government will do its duty in providing the means of carrying on this line of research. At present it may truthfully be said that the field is vast, but the labourers are few.

Lord Rosebery and the Hospital.

IN our recent article on the hospital question we pointed out in what respect the character of the hospital of to-day was changing from what it was some years ago. No longer is a hospital regarded as an institution limited in its purpose to the relief of the sick poor. Lord Rosebery seems to be in favour of organizing some hospitals on the same principles as those on which clubs, insurance companies, and other co-operative societies depend for their support. The hospital at Bishop Auckland will not depend on charity in any form, but on the contributions of those for whose benefit it is intended namely for the miners themselves. The question of chief interest to the profession is how it can best serve the good of society by assisting in the satisfactory arrangement of hospitals of this character. There seems to be rather a tendency on the part of the public to leave the profession very much out of the calculations in this matter. It is assumed that the medical and surgical work can be obtained much in the same way as any of the common necessities of a club or institution, and that contracts can be made much in the same way as for any articles of trade. To some extent this may be true, but how far it is so requires to be distinctly understood both by the profession and those who are disposed to follow the example set at Bishop Auckland. There may be no difficulty in organising a co-operative hospital on the same lines as an insurance company, but if the chief article required for the satisfactory working of such an association is not taken into much account, the association will fail in its chief purpose. If the profession should be seriously injured by such a system the public would suffer. If one of the objects of such co-operation is to cheapen as much as possible the

service of the profession, troubles will attend it. It would be well for Lord Rosebery and others well capable to deal with this question to be careful how they give support to a movement which is not as simple in its practical working as they might at first suppose. One of the chief difficulties which the provident dispensaries have to deal with is the securing of efficient medical and surgical treatment for members. It is unreasonable to expect the profession to give its labour for inadequate payment, for the majority of the profession cannot work unless it is properly paid. If charity is to be called upon to support this system it at once loses its character, and the results will be disappointing. This is a subject deserving the serious attention of the whole profession, and we trust that it will be considered as such in a sensible and proper manner.

Labori's Bullet Wound.

AN illustrated contemporary, *Black and White*, has with a good deal of enterprise presented English readers with a reproduction of the radiogram showing the bullet wound in Maitre Labori's back. So far as one can judge the missile has been arrested to the right of the spinal column somewhere between the fifth and sixth vertebræ. Less than an inch to the right, or two or three inches to the left, and the wound would have infallibly killed the illustrious advocate. On this side of the Channel it is hard to comprehend the fatuous psychology of attempting to settle a criminal trial by shooting the prisoner's counsel. It is not a little remarkable how quickly Labori recovered from the shock and was able to walk daily down to his labours in Court "with the anti-semitic argument in his back." Fortunately, this successful result of the new method of Röntgen photography has furnished a crushing reply to the report circulated by a few of the least scrupulous journals that the attempted assassination was merely a little theatrical spectacle arranged by Labori himself to further his own ends. The bullet displays a curious little "tail" of lead—a long, thin scrap, the thickness of fine twine, apparently shaved off by contact with an outstanding process of bone. The congratulations of the British public have been already showered upon this brave man and great lawyer, and will be echoed with peculiar force by members of the medical profession, who naturally recognise with more exact appreciation the hair-breadth escape of Labori from the point-blank shot of the dastardly miscreant, apparently destined to escape the toils of justice.

The Hospital Reform Association.

A CONFERENCE will be held next month under the auspices of the above Association to discuss various topics of vital importance to the medical profession. Its work will be distributed over two days, October 10th and 11th at the St. Martin's Town Hall, London. The three subjects chosen for discussion are (1) The enquiry system; (2) Payments by patients; (3) Provident dispensaries. It is to be

hoped that these meetings will be attended by many general practitioners, who here have an opportunity afforded them of laying their views and experiences before those influential laymen in whose hands, after all is said and done, the coming reform of the hospitals must lie. Unless medical men will attend meetings of the kind initiated by this energetic body, the world will never be persuaded that abuses exist in our great medical charities. At last year's conference in St. Martin's Hall a flood of light was thrown into the inner workings of the mind of some who pose as world-wide philanthropists. Further particulars of the forthcoming meetings may be obtained from the honorary secretary, Dr. Garrett Horder, of Cardiff, whose unceasing efforts in the direction of hospital reform deserve to be rewarded by crowded and enthusiastic meetings next October. It is particularly desired that medical men desirous of taking part in the discussions will send in their names to the secretary at the earliest possible date.

Salivary Superstitions.

APROPOS of our paragraph of a fortnight ago as to the unsavoury habits among many peoples based upon traditional tales of salivary virtues transmitted to them from the past, it might be worth our while to add another example to our former list. This example of the widespread belief in the wonderful powers possessed by saliva, is, however, less allied to imaginative superstition, but rather seems to savour of empiricism. In parts of Scotland, it may be throughout Scotland and perhaps in England, warts on the hands are supposed to vanish with great celerity should they be anointed each morning with the first spittle formed by their owner's salivary glands after awaking. The most extraordinary part of the story is that there seems to be some truth in the results following this procedure. On more than one occasion endeavours to eradicate the growth of warts on the hands of children, successful enough in so far as the destruction of the actual warts present at the time of treatment was concerned, but unsuccessful in the prevention of new crops, were desisted from, and, mostly owing to a feeling of curiosity as to the effect produced by a popular method of treatment, superseded by permission as sought for to soak the warty area in the spittle first secreted on awaking each morning. The idea appeared more than ludicrous; to be on a par with mediæval

"Eye of newt, and toe of frog

Wool of bat, and tongue of dog."

But the result was no less surprising. Whatever the explanation may be in truth, due to coincidence, or to some real property, in several instances we have watched the death of the warts and the non-appearance of a further crop. Canine wounds are almost invariably said to heal best if treated solely with the injured's tongue, and there is no doubt that solutions of continuity in the integument of dogs present healthy signs and escape septic invasions in apparently much larger proportion than such wounds would show in man were he to confine his treatment to oral and li gua applications. We

are unaware of any observations as to the properties of the saliva secreted by the dog and his allies, but know that human saliva is markedly pro-septic. If its action upon the skin's tendency towards generating of warts be true, as smoke argues fire, so belief must have base, and tradition may be possibly right. Unless the small proportion of alkali of the saliva be the beneficial agent, the actual underlying cause is far to seek. Can the salivary glands be the producers of some dermatic tonic, like unto the products of other glandular tissues? Or is the "first spittle in the morning" a salivary superstition?

The Metric System.

THE Associated Chambers of Commerce, at their meeting on the 6th inst., adopted, almost unanimously, the following resolution:—

"That the Association, reaffirming its frequently expressed opinion that the metric system of weights and measures should be made compulsory in the United Kingdom, strongly urges her Majesty's Government to use it in all Government departments, and to strictly enforce the existing provisions in the Education Code with regard to the teaching of, and examinations in, the subject in elementary schools, and that representations to this effect be made to the Government."

Four resolutions to the same effect were on the notice paper, emanating from such commercial centres as Birmingham, London, Bristol, and Leicester, but they were all withdrawn in favour of the above. The advocates of the resolution urged, of course, the great stimulus given to foreign commercial competition by the continuance of the out-of-date British system of weights, measures, and currency, and we are able to endorse their arguments by pointing out that chemistry, pharmacy, and other cognate subjects lag behind the time in England, because none but the *cognoscenti* are able to translate our ounces, drachms, pints, quarts, inches, yards, and acres into their metric equivalents. It is to be hoped that our Government will respond to the above resolution by at least making a start towards reform.

The Congress of the Institute of Public Health

WILL open in Blackpool on September 21st under the presidency of the Marquis of Lorne, who will deliver an inaugural address. The usual division of the work of a Congress among sections—each dealing with its own speciality—will be made. A feature of the Health Exhibition, in connection with this Congress, will be special exhibition and discussion on smoke abatement. The Congress is expected to attract a large number of members of the Institute and visitors.

A REQUISITION has been presented to the Lord Mayor of Belfast to convene a public meeting to consider the propriety of inviting the British Association for the Advancement of Science to visit that city. The requisition has been very influentially signed.

The Medical Administration of Gaols in Scotland.

THE Secretary for Scotland has appointed a Departmental Commission to investigate the housing, nursing, and dietary of prisoners, and certain other subjects bearing thereon. The Earl of Elgin as chairman, and Sir Thomas Carmichael, Sir Batty Tuke, and Sir Colin Moncrieff are members of the Commission.

France.

PARIS, September 10th, 1899.

TREATMENT OF GUNSHOT WOUNDS IN THE BACK.

The gravity of gunshot wounds in the dorsal region varies essentially with the diameter, the weight, and the speed of the projectile.

The bullets, says Dr. Auscaler, of ordinary revolvers do not possess a great power of penetration. These projectiles, which do not weigh more than sixty or eighty grains, are frequently fired with an initial speed of only 160 yards. Consequently they cannot pierce tissues of any resistance, glide upon bones of small dimensions, or are arrested by their contact without breaking them. The gravest cases are those where the projectile meets only with soft tissues. The bullet in such cases can penetrate even to the mediastinum and lodge in the immediate neighbourhood of the heart and the large vessels without wounding them or producing the slightest immediate accident. Death ensues later on from internal hæmorrhage, or the formation of an abscess at a time when the patient was considered cured. Projectiles, on the other hand, of great speed act differently. The Lebel ball, for instance, which has an initial speed of 700 yards per second, and capable of piercing through six men walking in Indian file produces quite different lesions. The projectile causes a wound much the more grave when it touches the osseous system. As an example of the chances afforded by the modern rifle, Dr. Auscaler cites the case of a prisoner who in attempting to escape was shot at a distance of six yards, and pierced right through in the region of the liver. The man fell from the shock, but in eight days he was perfectly well. The ball of an ordinary revolver would have probably lodged in the liver and produced by subsequent inflammation fatal results. On the other hand, if the ball of a rifle struck the back in the median line, shaving as it were one of the transverse processes, it would smash to pieces the vertebra and cause immediate death from wound of the medulla, while the projectile of a cheap revolver would not produce any important lesion, it would be simply arrested by lamina of the vertebra as in the case of M. Labori, recently wounded at Rennes.

The approximative diagnosis of the seat of the projectile can be determined almost at the outset according to the symptoms observed.

If no hæmoptysis occurs, and if no symptoms of internal hæmorrhage be present, the wound is most probably localised in the soft parts of the posterior wall of the thorax. The wounded man rarely loses consciousness. The first symptom which should be sought for is paraplegia. If no sign of paralysis exists the wound is almost always benign. Where paraplegia is present a cure is rarely obtained, for almost always the medulla is cut across, and sutures never were successful. Sometimes, however, the medulla is simply compressed by the projectile or by a bony fragment. In any case where paraplegia is present surgical interference is imperative as soon as the patient has recovered from the shock and the foreign body removed. The paraplegia, however, will persist.

In cases where no paraplegia exists surgeons were not agreed as to the conduct to be observed. Some say that, as no important organ has been touched, matters should

be left alone, while others pretend that a projectile lodged in the neighbourhood of the mediastinum, the patient is in permanent danger of prevertebral suppuration. The opinion of Dr. Auscaler is that intervention is here as necessary as in the first case, with the advantage that a perfect cure can be expected.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, September 9th, 1899.

HOW FAR CAN WE DISINFECT OUR HANDS?

ONCE again this question has come up for discussion. This time the inquirers are Drs. Gottstein and Blumberg, who publish the result of their research in the *Berl. Klin. Wochenschr.* 34/99. Döderlein at the Surgical Congress, 1898, declared that the hands could be rendered perfectly sterile, that therefore Mikulicz's gloves for operation were at least superfluous if not positively harmful, and it was for the purpose of testing the accuracy of the declaration that the author undertook new and independent inquiry. Up to three years ago the method of disinfection in use in Mikulicz's Klinik was that of Fürbringer—viz., three minutes scrubbing in hot water and soap, one to two minutes soaking in a 6 per cent. solution of alcohol, and finally scrubbing with a 1 per 1,000 solution of perchloride of mercury. As the results of such disinfection were glaringly unsatisfactory, the periods were lengthened to eight to ten minutes hot water and soap, three minutes alcohol, at first 36 per cent. then 50 per cent., and at last 70 per cent. in strength, and then 2 to 3 minutes with sublimate solution as before. The results were now so much improved that the hands were infested with germ in 53 per cent. of cases instead of 61·3 per cent. as before. For scientific purposes the different procedures in stages of the disinfecting process were now prolonged further than would be possible in practice, with the result that the germs were reduced in number; although they were still present. In 29 per cent. germs were still there. The germ almost always formed after completed disinfection was the staphylococcus albus. This showed that the germs on the skin were indeed removable, but that the normal epiphytes of the skin could not be removed. Bischoff has shown that in a certain number of cases the staphylococcus albus possesses pathogenic properties, and this being so, it is evident that in making or treating wounds there is always danger of infection from the surgeon's own hands. It was this evident danger of infection that led to the introduction of the glove by Mikulicz. Knitted gloves have always been used worn by Mikulicz with satisfactory results. The authors, speaking of the good results obtained by Döderlein with Friedrich's indiarubber gloves in obstetric operations, maintain that this shows the enormous value of a covering for the hand. The Mikulicz glove has the advantage over the Friedrich that it can be changed oftener. It is of course understood that the hands must be as carefully disinfected as if no gloves were worn, so long as an impermeable covering for the hand is not procurable.

The authors sum up to the effect that absolute removal of all pathogenic germs is not possible by any method of disinfection, that, however, their numbers can be materially reduced.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, September 16th, 1899.

PREMATURE LABOUR.

At the "Naturforscher Versammlung" Hücklenbroich raised a discussion on the utility of inducing premature labour in severe and dangerous cases. During the sixteen years he had devoted his attention to the subject he

had performed 60 operations on 29 females. In 26 of these cases the operation was on account of a narrowing of the pelvis; the other three were due to uncontrollable vomiting and carcinoma of the pylorus. In the "flat" pelvis the conjugata vera was never less than 8 centimetres (3.177 in.).

Of the 29 females who had the operation performed, 16 had it performed once, six had it performed twice, one had it three times, two had it four times, three had it five times, and one had it six times. One died after the fifth operation from septic peritonitis. A rise of temperature occurred in other three from septic poisoning, one had pneumonia, and another had an elevated temperature for twenty-four hours from catarrh of the stomach.

Forty-eight of the children were born alive, but twenty-one of these died in hospital before leaving, thus proving their weakness to resist the force of living ex-utero. Twins were born once, making in all sixty-one children. In respect of the position ten were cross births, seven feet, four buttocks, one brow, and one face.

Three times the umbilical cord prolapsed, three times the instruments were applied, once perforation was resorted to, and in eight of the cases cramps were so violent as to retard labour, and were alleviated by means of opium, warm baths, and rubefacient paints.

The weight of the children ranged between 2,250 to 3,000 grammes—4.96 to 6.6 lbs. The method of performing the operation was that recommended by Krause, by inserting a bougie and occasionally turning it to induce contractions; the bougie is held in position by tampons of iodoform gauze tightly packed into the vagina and, if no pains within twenty-four hours, the dressing is renewed. No anæsthetics should be given. It is worthy of note that a good thick bougie should be used as small ones are disappointing. As a rule pains commence in a few hours, or within six or twelve hours, although it is not unusual to run into two days. The birth usually terminates in eighteen hours to seven days.

In the mother that died from sepsis the pains had gone on for five and a half days, when severe bleeding commenced, necessitating the opening of the cervix and extraction of the fœtus. Four hours after delivery the mother developed tetanus, dying on the fifth day from peritonitis. The child died on the third day from erysipelas.

Fehling was the first to open the discussion, and said that these facts all tended to prove what he has long taught that premature labour should be more frequently practised than it usually is at the present time by the general practitioner, when the pelvis has an exit of not less than eight centimetres in the conjugate. He objects to Krause's method of performing the operation as dangerous. He prefers using a modification of Barnes' "Colpeurynter" to the bougie which never should be used, as it goes too high up in the uterus for any practical use beside the danger of transmitting infection which is always to be avoided. The "vagino-cervix colpeurynter" is the quicker and safer instrument.

Hofmeir considered both of the foregoing instruments far too dangerous for every day use and recommended Kehrer's method of iodoform gauze tampons as safe and effectual. He admitted that this method does not bring on the pains as quickly as either of the above. When the cervix is open the "Colpeurynter" may be used to hasten the operation.

Mertens said he had obtained far better results with the bougie than he ever had with Fehling's modified Barnes' "Colpeurynter."

Continental Health Resorts.

[FROM OUR SPECIAL CORRESPONDENT.]

BRIDES-SALINS (SAVOY).

BRIDES-LES-BAINS, until recently, has been rather difficult of access, even from the chief Savoy Spa of Aix-les-Bains; for going even the short distance from Aix, travellers had to change railway carriages, or wait an hour or so at Chambéry, change again at St. Pierre,

wait another hour at Albertville, and drive from the railroad terminus at Moutiers up to Brides. The Paris, Lyon, and Mediterranean Railway Company have this season given some direct trains from Paris (via Aix-les-Bains) to Moutiers (promising more direct connections for next year), and an electric tramway is now constructed from Moutiers to Brides. These improvements will make Brides-Salins easily accessible from England.

Brides and Moutiers-Salins are two distinct health stations, belonging to one company and under one management. These twin stations are only two miles apart; their waters are frequently used together, and the communications between them are so easy that they really form one and the same watering-place. They are situated in the heart of the Tarentaise Alpine region, the most picturesque part of Savoy, rivalling, with its great glaciers and superb mountain scenery, anything of the kind to be seen elsewhere in Europe.

Moutiers, the P.L.M. railway terminus, is a town of prehistoric antiquity, and its immediate neighbourhood affords much of archaeological and geological interest. Many venerable traditions cluster around it. Even in Hannibal's time it was an ancient city, and his passage through these Tarentaise defiles and gorges cost him much time, labour, and the sacrifice of many veteran soldiers, and the irremediable loss of most of his most potent military force, the elephants, in the first years of his Italian campaigns a novel terror to the Roman armies.

The Salins-Springs and Bath Establishment are about a mile from the town of Moutiers, on the road to Brides. Salins was itself an important town until submerged by the avalanche of almost an entire mountain in the fifteenth century. Now it is a hamlet, containing only the baths, with their adjoining hotel and park, some comfortable pensions, villas, and houses let out in furnished apartments.

The more desirable place of residence is at Brides, a pleasant village with excellent hotels, good Casino and reading-rooms, English and French churches, boarding houses, and furnished flats and cottages; affording both to invalids and to pleasure-seekers an agreeable summer home from May to October; the preferable months for British visitors to Brides are from the middle of May until July, and from early September to the middle of October. "The season" at Brides-Salins opens officially on May 15th and closes October 15th.

The leading hotels are the "Grand Hôtel des Thermes," "Hôtel de France," "Nouvel Hôtel," and the "Grand Châlet," all ably conducted by the same proprietors, Mr. and Mrs. Robin. There are various other good hotels, as the "Grand Hôtel" of Mr. Lafont, opposite the Catholic church.

The "Grand Hôtel des Thermes" has interior communications with the bath establishment at Brides, and is in the same park as "The Casino" and the "Grand Châlet."

Brides is also well supplied with thoroughly competent physicians; amongst them Dr. P. Delastre, so favourably known to many of the profession in London, Edinburgh, and Dublin, who has written much both in French and in English on the Brides and Salins Springs.

The Doctors Laissus (father and son), Dr. Desprez, and Dr. Emile Philbert, have also ably advocated the claims of these twin-stations. Likewise Dr. D. W. Samways, who practices at Brides in the summers, and at Mentone, Riviera, during the winters. An analytical laboratory, well equipped and directed by Mr. Boumat, is attached to the Moutiers-Salins establishment.

The Saline Baths form the basis of the treatment at Moutiers; the water is also much drunk for its thermal properties and its large proportion of carbonic acid gas. It is tonic and stimulating, especially upon the circulation, strengthening and increasing the pulsation, and its beneficial action is very remarkable upon the glandular system. Glandular swellings, diseased joints, emaciated limbs, anæmia, diseases of women, and fibrous growths are special indications for these Salins.

The springs at Brides itself are highly efficacious for diabetes, dyspepsia, gout, corpulence, constipation, kidney and liver troubles, and most maladies of the intestines.

THE TREATMENT OF CHRONIC PHARYNGITIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have no desire to express any difference from the views of Dr. Woods on the importance of nasal obstruction as an etiological factor of chronic pharyngitis; on the contrary I cordially agree with them. But I venture to suggest that it was recognised long before "a considerable number of these cases" could have "passed through his hands." Nor can it be admitted by any one who can lay fair claim to be considered a throat specialist that "the necessity for rhinoscopy in throat disease was only pointed out a few years ago." The art of rhinoscopy dates from a paper published by Czermak (*Wien, Medicin Wochenschrift*, August 6, 1859), which was only fifteen months after the first publication in the same journal on the art of laryngoscopy as practised by him, the form, indeed, which it has ever since remained to us. I am indebted for these facts to the third edition of "*The Laryngoscope*" published in 1871, by (Morell Mackenzie who, in an appendix, gave every detail necessary for rhinoscopy, and illustrative cases demonstrating its utility.

Without in the least desiring to detract from the merits of other teachers, I may be allowed to state my own position. In the first edition of my systematic work published in 1878—ten years before Dr. Woods took his degree—I wrote:—"Nasal respiration is often obstructed in certain pharyngeal diseases. . . . No examination of the throat is complete without careful inspection of the nasal passages through both anterior and posterior nostrils, and also where symptoms point to disease of the naso-pharynx, by means of the index finger introduced upwards behinds the velum, though these are points much neglected both in precept and practice." (P. 43.) In later editions, especially in the third published in 1890, these points are still more strongly enforced as evidenced by the remark that "the first indication (against recurrence of chronic pharyngitis) is to establish actually free nasal respiration." (P. 198.)

While making this reclamation in favour of the position of the specialist on this subject, I fully agree with Dr. Woods that the importance of free nasal respiration, not only in chronic pharyngitis, but in affections of the whole of the respiratory and auditory passages, is not yet sufficiently recognised either by the leaders of general surgery or by the general practitioner, but this is no fault of the specialist. The article of Dr. Woods may reasonably be expected to result in a more extended appreciation.

I am, Sir, yours truly,

LENNOX BROWNE.

Mansfield Street, W.,
September 8th, 1899.

NURSES OF THE LATEST FASHION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The "interest and vitality" of Mr. Gant's literary achievement may have suffered, as he complains, from your curtailing pen, but the only fault I personally find with the process of which he complains is that it did not extend to complete excision. Briefly, I regard his sketches as a prurient and indefensible attack upon a sisterhood which deserves tender treatment from all mankind, and most of all at the hands of the medical profession. He may qualify his statements as he likes, but they will go out to the world as aimed at trained nurses in general.

Take the men or women of any class of the community from the Royal court to the East-end court, and you will find a certain percentage worthless and criminal. In the modern nursing profession, I venture to assert that the average moral tone is far higher than that of any other class of the community drawn from similar stations of life. That statement applies to skilled nurses

and not to social failures who have drifted into nursing as a mere means of livelihood. Supposing some writer of ability was to dip his pen in gall, and deck out in literary form the histories of the medical men at present lying in gaol, could that be taken as fair commentary upon the character of the main mass of their profession? Yet that is the principle Mr. Gant adopts in dealing with nurses. He would find no difficulty in writing a series of sensational articles on the moral delinquencies of men in holy orders, founded on the criminal history, say, of the past ten years. Why fix on a defenceless class of women? Why pen Philippics against womankind to the exclusion of the sex that plays no inactive part in the drama of life's treachery? Yet, Mr. Gant thinks that such men as the father and son he describes should be protected "from marriage in spite of their depravities."

Christian charity and kindly tolerance one looks for in a gentleman who has passed many years in the exercise of a liberal and humane profession like that of medicine, those qualities are not conspicuous in Mr. Gant's articles.

I am, Sir, yours truly,

Bentinck St., W.

DAVID WALSH.

Munificences to the London Hospital.

THE race of large-hearted, wealthy patrons to hospitals is not exhausted by any means, witness the recent gift of £10,000 by Mr. E. Raphael towards the establishment of a new Jewish ward at the London Hospital. Along with this announcement is that of a gift of £60,000 made by the executors of the late Baroness de Stern towards the establishment of a convalescent home.

Venereal Disease and Marriage.

A LAW has just been passed by the Michigan legislature forbidding the marriage of persons suffering from gonorrhoea or syphilis, offenders being punishable by a fine of from 500 to 1,000 dols. or a term of imprisonment not exceeding five years. No limit of time appears to have been imposed, so that the fear of proceedings may remain as a sword of Damocles held over the head of the erring party to the contract for an indefinite period; moreover, professional secrecy is to be abolished in respect of such actions. It is one thing to make such a law and another to enforce it. Were it otherwise it is probable that similar legislation would long since have graced our own statute book.

A Gallant Rescue.

DR. MARTIN, of Gifford, near Wigan, narrowly escaped drowning last week when bathing at Douglas, Isle of Man. The sea was rough and the tide high, and he was in sore plight, when a lad of 13 went to his assistance, and after several attempts was successful in bringing him to land. That, at least, is the version given by a local newspaper, and if correct, every praise is due to the plucky youngster who thus prevented the depletion of the ranks of the profession.

A Surgical Catastrophe.

WE regret to have to record the death of Dr. William McLaurin, of Barnsbury, from pyæmia, consequent upon a trifling injury received during an operation for removal of the tonsils, which took place a few days since. He at first made light of the matter, and when Mr. George Brown was called in the disease had already made such strides that treatment was powerless to avert a fatal result.

Death from Anthrax.

ANOTHER death from anthrax is reported to have occurred at Worcester, where a lad, æt. 13, employed at a horsehair factory, died of the disease, induced, it is believed, by his scratching a pimple while engaged in manipulating horsehair imported from abroad. This is the third death which has occurred in Worcester from this cause within the last few months.

The Peculiar People Again.

AN adjourned inquest was held at Canning Town on the 5th inst. on a child, æt. 17 months, who had died of bronchitis in the absence of medical attendance. The jury on the former occasion failed to agree on a verdict, and they were not more successful at this, the resumed, inquest, so the coroner adjourned the inquiry to the Old Bailey.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

NOTICE TO HOSPITAL AND COLLEGE DEANS.

THE Editor desires to thank those gentlemen attached to the various Medical Schools and Hospitals for supplying him with the information from which the foregoing pages have been composed.

NOTICE TO OUR READERS.

As this number is mainly devoted to information necessary for students intending to join one or other of the various Medical Colleges, and for those who, having passed their curriculum, are about to enter the ranks of the profession, much of the ordinary matter which usually fills our columns is necessarily deferred till next week. Should any of our readers desire to present this number to a patient or friend who contemplates sending his son to a medical college, our Publisher will be happy to supply him with a duplicate free of cost on receipt of address.

A PICTURESQUELY WOODED MEMORIAL.

The *Indian Lancet* publishes a memorial received by an administrative medical officer in India, praying for the removal of a native subordinate in favour of a rival, couched in terms not usually embodied in documents of the kind. The officer whose translation is desired is described as "a superannuated, lethargic, diabetic, worn-out dry stick of humanity," and the unhealthiness of the place is ascribed to the "foul-mouthed vituperations, peevish ravellings, and short temper of the old diabetic Æsculapius" in question. The memorial winds up with the expression of a hope that the authorities would shortly see fit to rid them of "this old man of the woods." Even the most intemperate guardian, in his desire to obtain the dismissal of a medical officer, stops short of eloquence of this kind, though the difference is sometimes more of form than of substance.

DR. HORDER (Cardiff).—Next week.

MR. W. J. CORBET, M.P.—Your letter is unavoidably held over in consequence of pressure on our space by educational material.

DR. J. CONOR (Buenos Ayres).—Communication to hand is marked for early insertion.

DR. DUKE (Cheltenham).—We are a little surprised that our contemporary inserted the letter, which is an advertisement of a proprietary article, but more so that the author, who is admittedly one of the foremost men in the profession, should allow it to be printed and circulated broadcast as an advertisement. There would be a sudden outburst of indignant remonstrance if such a thing emanated from among the rank and file.

DR. COSGRAVE.—See reply to Dr. J. Conor.

C. S. G.—The Army Medical Service Corps does not confer any privilege in respect of the regular study of medicine, and it would be idle to base any plans on such an assumption. You must be under a misapprehension as to the nature of the duties devolving on members of that corps.

DR. N.—Technically, no doubt, the consultant was in the wrong, but as he duly communicated with you and declined to further attend the patient, we cannot hold that you have any tangible ground for complaint.

Vacancies.

Barnwood House Hospital for the Insane, Gloucester.—Junior Assistant Medical Officer. Salary, £120 per annum, with board, &c., rising to £140 per annum.

Borough Asylum, Portsmouth.—Junior Assistant Medical Officer. Salary commencing at £120 per annum, with board, lodging, and washing.

County Asylum, Prestwich, Manchester.—Assistant Medical Officer, unmarried. Salary commencing at £125, with board, apartments, washing, &c.

Cambridgeshire, &c., Lunatic Asylum, Fulbourn, near Cambridge.—Assistant Medical Officer. Salary, £140 per annum, with board, lodgings, and attendance.—Applications to the Clerk to the Visitors, Cambridge.

Manchester Clinical Hospital for Women and Children, Cheetham Hill.—House Surgeon. Salary, £90 per annum, with apartments and board.—Apply to the Secretary, Barton Arcade, Manchester.

Metropolitan Asylums Board.—Two Assistant Medical Officers at Darenth Asylum, near Dartford, Kent, and one at the Leavesden Asylum, near Watford, Herts. Salary, £120 per annum, rising, conditionally, to £150, with board, lodging, attendance, and washing, subject to statutory deductions.—Apply at the office of the Board, Norfolk Street, Strand, London. (See advert.)

North Staffordshire Infirmary and Eye Hospital, Hartshill, Stoke-upon-Trent.—House-Surgeon. Salary commencing at £120 per annum, with furnished apartments, board, and washing.

Queen's Colleges, Ireland.—Professor of Medicine in the Queen's College, Belfast.—Apply to the Under Secretary, Dublin Castle. Royal Albert Asylum, Lancaster.—Resident Medical Officer. Salary, £400 per annum, advancing to £450, with furnished house, coals, gas, milk, and vegetables.

Royal Sea-Bathing Hospital, Margate.—Assistant Resident Surgeon. Salary, £52, with board and residence.—Apply to the Secretary, Royal Sea-Bathing Hospital Offices, 30, Charing Cross, London. Royal South Hants Infirmary, Southampton.—House Surgeon. Salary, £100 per annum, with rooms, board, and washing. Stoke-upon-Trent Union.—Resident Medical Officer for the Workhouse. Salary commencing at £100, with board, washing, and furnished apartments at the hospital.—Apply to the Clerk to the Guardians, Union Offices, Stoke-upon-Trent. West Herts Infirmary, Hemel Hempstead.—House Surgeon and Dispenser, unmarried. Salary, £100 per annum, with furnished rooms, board, fire, light, attendance, and washing. Whitehaven and West Cumberland Infirmary, Whitehaven.—House Surgeon. Salary, £120 per year, and £30 annually for dispensing, with furnished apartments and attendance.

Appointments.

BRENNER, C. S., M.B., Ch.B. Edin., House Surgeon to the Durham County Hospital.

DAVIES, L. G., M.D. Cantab., Medical Officer for the Workhouse and the Children's Homes of the Middlesexborough Union.

EDINGTON, GEORGE H., M.D., M.B.C.S. Eng., L.R.C.P. Lond., F.F.P.S. Glasg., extra Dispensary Surgeon to the Royal Hospital for Sick Children, Glasgow.

GALLWEY, T. J., C.B., M.D., M.Ch. Irel., President of the Board of Medical Officers to examine candidates for commissions in the Army in London.

HAWKINS, WM., M.B.C.S., Medical Officer for the Upway Sanitary District of the Weymouth Union.

LIVINGSTONE, THOS. H., M.B., Ch.B. Edin., House Surgeon to the Rochdale Infirmary.

MACVICKER, C. G., M.B., B.Ch. Irel., Medical Officer for the Fourth Sanitary District of the Wells Union.

MAYNARD, G. D., M.B.C.S., L.R.C.P. Lond., Junior Out-patient Surgical Officer to the Royal London Ophthalmic Hospital.

MORRIS, J. J., NIXON, L.R.C.P. Lond., M.B.C.S., (Honorary) Assistant Surgeon to the Royal Albert Hospital, Devonport.

PATCH, H. H., L.R.C.P. Lond., M.B.C.S., Medical Officer for the Second and Third Sanitary Districts of the Hertford Union.

RAYNER, H. E., F.R.C.S. Eng., L.R.C.P. Lond., Medical Officer and Public Vaccinator for the Frimley District.

ROBINSON, E., M.D. Edin., C.M., Medical Officer for the Frensham Sanitary District of the Farnham Union.

TAYLOR, FRANK E., M.A., M.B., M.Sc. Vict., M.B.C.S., L.R.C.P., Assistant Resident Medical Officer to Queen Charlotte's Lying-in Hospital, London.

TETLEY, T. W., M.B.C.S., L.R.C.P., a House Physician to the General Infirmary at Leeds.

THURNELL, H. L., L.R.C.P. Lond., M.B.C.S., Medical Officer for the Gravesend Sanitary District of the Gravesend Union.

WILKIN, G. C., L.R.C.P. Lond., M.B.C.S., Medical Officer for the Second Sanitary District of the Yeovil Union.

Births.

COLBECK.—On Sept. 5th, at Porchester Terrace, Hyde Park, W., the wife of E. H. Colbeck, M.D. Cantab., M.B.C.P. Lond., of a son.

WARREN-DAVIS.—On Sept. 5th, at Dorset Square, the wife of John Warren-Davis, M.B.C.S., L.S.A., of a son.

Marriages.

BENNETT-DEAKIN.—On Sept. 7th, at St. Peter's Church, Dulwich Common, William G. Bennett, LL.B., M.B.C.S., L.R.C.P. Lond., youngest son of William Bennett, of Worcester, to Jessie, only daughter of W. H. Deakin, of Worcester.

BLOMFIELD-MILES.—On Sept. 5th, at St. Nicholas Church, Sutton, Surrey, Alfred Bealy Blomfield, M.B.C.S., L.R.C.P., L.S.A., third son of Josiah Blomfield, M.D., F.R.C.S., of Peckham, to Ellen Mary (Nellie), only daughter of John Frederick Miles, Esq., of Sutton.

DASHWOOD-HOWARD-BETTS.—On Sept. 6th, at St. James's Church, Hampton Hill, S.W., Arthur Dashwood-Howard, B.A., M.D., M.B.C.S., L.R.C.P., F.R.M.M., only son of J. Jackson Howard, LL.D., F.S.A., of Blackheath, Kent, to Melita Margaret, only daughter of the late Walter Betts, of Gately Hall, Norfolk.

NEWTON-ADAMS.—On Sept. 7th, at St. Stephen's, South Dulwich, Herbert W. Newton, M.B.C.S., eldest son of the late Rev. M. A. Newton, to Florence Betrice, youngest daughter of Frederic Emilius Adams, of West Dulwich.

RUSSELL-CURRIE.—On Sept. 5th, at Stephen's Church, Edinburgh, Francis Rutherford Russell, M.D., Guildford, Surrey, to Mary Maxwell, second daughter of James Currie, Trinity Cottage, Edinburgh.

Deaths.

BYRDEN.—On Sept. 6th, suddenly, at Culm House, Southsea (the residence of his eldest daughter), of gastro-enteritis, Richard Bryden, M.B.C.S. Eng., L.A.H. Dubl., late of Uffculme, Devon, in his 89th year.

HOGGEN.—On Sept. 4th, suddenly, at his residence, Strathmigh, Fifeshire, Edgar Hogben, M.D., in his 39th year.

IRELAND.—On Sept. 11th, at Marivish House, Polton, Midlothian, Margaret, the wife of William W. Ireland, M.D., Medical Superintendent.

TAYLOR.—On Sept. 8th, after a short illness, Alfred Augustus Taylor, M.B.C.S., L.S.A., of Kingston Hill, Surrey.

Original Communications.

THE "DE NOVO" ORIGIN OF SYPHILIS.

By JOHN A. SHAW-MACKENZIE, M.D. LOND.

IN the kind notice of a paper of mine (1) in an Editorial article in THE MEDICAL PRESS AND CIRCULAR of June 21st, request is made for further information regarding my "casual" reference to the *de novo* origin of syphilis. I would at once point out I used the term *de novo*, as I have elsewhere done (2) in the sense it has been used by various authorities in the past—viz., syphilis arising from promiscuous sexual intercourse apart from transmission.

The origin of syphilis has at all times been an interesting question. One set of authorities have contended for the existence of syphilis from all time; another set for its introduction into Europe at the end of the fifteenth century, and another for its *de novo* origin not only at that time, but constantly. The former and latter view was independently advanced by Fergusson, and I more especially noted the latter as evidence against the "extinction" of syphilis in Portugal, as erroneously in my opinion credited to him. "That Columbus," he wrote, "should have brought it from the innocent natives of the Carribee Islands is a fable too weak to be credited. The first devastations may have been contemporaneous with his return from the West Indies: but he found it in the stews of Madrid or the sea-ports, amidst the unspeakable abominations of common prostitution in the same way as at an after period the troops under the miseries and privations of the siege of Naples, where the women who followed the camp must have been of the most abandoned and revolting description, adopted the belief of its having originated there. In fact, I believe, with my friend, Mr. Guthrie, that whenever prostitution is foul and unclean, restricted to few women amidst crowds of men, there the infection will be generated which afterwards spreads through society at large." (3) "It would be altogether foreign to the scope of this work," wrote Erichsen, "were I to enter into the very curious and interesting question as to the origin of syphilis, a subject that admits of much dispute, and which has been keenly argued. After an attentive examination of it I think there can be little doubt that syphilis was either introduced into Europe or originated there *de novo* towards the end of the fifteenth century." (4)

Holmes Coote supported largely the *de novo* origin, while Acton opposed it. "I may at once state my opinion," wrote the former, "that gonorrhoea and syphilis are co-existent with promiscuous sexual intercourse as practised by the inhabitants of Europe, i.e., where one woman receives several men. They scarcely exist among the inhabitants of the East where the practice of polygamy is universal, unless

indeed it has been introduced, as is the case in our Indian possessions by the formation of large military depôts or the construction of cities. The conditions necessary to call forth the venereal disease seem to be the same universally, namely, large assemblages of men with an inadequate proportion of females.

"In 1855 I was stationed for a few months in Smyrna, and was struck at once with the rarity of venereal disease—the same was noticed by me when visiting other places in Anatolia—of syphilis I saw nothing among any of the inhabitants. It appears then whenever large numbers of men are so placed that one female has connection with several of the opposite sex within the twenty-four hours for any length of time gonorrhoea and syphilis both become common. As regards the first, to which Mr. Acton has applied the term 'non-specific,' its spontaneous origin is admitted. Once developed it may be propagated by contact. Upon the question of the origin of the syphilitic virus there exists the greatest difference of opinion, and Mr. Acton hesitates to admit its spontaneous origin. 'All the experiments made to produce it *de novo* have completely failed, and a careful investigation of the disease shows, on the contrary, that it has been contracted from a person who has himself contracted it from another person.' Now I know of no series of experiments which any person has tried or would like to try, even if he had the power to ascertain this point. Let us for a moment consider the career of the female from whom a healthy man contracts a syphilitic sore. Originally virtuous, and, perhaps, an object of admiration, she receives as many men during the day as she can bear for the purposes of maintenance. Many of the lower order of prostitutes have informed the sister of the ward under my care that they have admitted seven or eight men a day, and perhaps even more. . . . It is, I presume, under circumstances like these that the source of the syphilitic virus must be investigated. What process then have we that it is not generated every day, and wherefore should we revive the hypothesis of Van Helmont, who attributed syphilis to farcy, transmitted from the horse to the human being, until we have clearly ascertained that none of our social habits are in fault?

"About ten miles from a station in Asiatic Turkey, to which I was appointed in 1856, was a large encampment of native cavalry in the pay of the British Government. I knew several of the medical officers, and was informed by them of the frequency among the men of primary venereal sores about the anus. The mode of communication may be understood without description; the vitiated habits of Orientals have not changed since the days of Cyrus. But the question arises, Whence came the poison? Was it introduced by someone who contracted the disease from a female? This is the most ready solution of the question; but then it is destitute of proof, and the difficulty of access to women in the East is proverbial.

"Dr. Gordon, surgeon, late of the 57th, now of the 10th, has shown in an interesting pamphlet not only that the relative prevalence of different forms of local ulcers varied according to the station of the regiment; but from the circumstance of the Hunterian chancre being most abundant in large garrison towns in England, such as Chatham, Canterbury, and Dublin, it may be presumed that the filthy habits of the prostitutes of such stations had something to do with the prevalence of this form, which is the most severe. . . . The prevalence of the severer forms of sore in densely crowded cities implies a power of aggravation of the virus through the deplorable habits of the female. Now if it could be proved that the poison remained under all circumstances the same, and that increase in its activity was due to its working upon a constitution on the side of the man impaired by excess, no particular inference already unacknowledged could be drawn. But if on the other hand it can be shown, as Dr. Gordon's statistics seem to prove that the poison may acquire a positive increase of virulence through habits of excess in promiscuous intercourse by the woman, I see no difficulty in imagining, that this is the source whence the poison may have originated from the beginning; that Nature has established laws, the transgression of which is followed by vitiation of the natural secretions producing poisons capable of acting upon the human frame in the same way as the decomposition of vegetable matter will produce the miasmata.

"I admit that the propagation of an unsound hypothesis is injurious, by diverting the mind from proper inquiry and by satisfying those who are easily captivated. We have no other course open, therefore, than to suspend our judgment whatever may be our bias, and to admit no new statements unless supported by recent investigation and the observation of facts." (5)

Acton, in opposition, relies on absence of well authenticated facts as opposed to convictions and errors in diagnosis in cases resembling syphilis of apparently spontaneous origin; he further adduces the case that came under the care of M. Rossignol in his *Aperçu* of the St. Lazare Hospital. It is the case of a young girl who had connection forty-seven times in twenty-four hours. No specific disease was found, but considerable inflammation, which soon abated by rest, antiphlogistics and low diet. If ever there was a case he argues, "to produce specific disease from excessive copulation, surely this was one." On the other hand, he quotes Carmichael: "From these circumstances we should be led to conclude that mild forms of disease are eternally arising from the sexual intercourse of even persons in health, and I have so often seen troublesome ulcers arise in men who had connection with women above suspicion, while they had on them at the same time crops of herpes præputialis, that I feel the more confirmed in this opinion." Acton agreed that excoriations, physically indistinguishable from chancres might arise. "We must, however, frankly admit it," he goes on to say, "that in the present state of science it is impossible to determine when or under what circumstances the virus and its effects first appeared; indeed, the origin of this as of a thousand other facts is entirely concealed from us, patent though their existence is. My own opinion is that syphilis in the human race originally arose from some poison introduced into the economy from animals or decomposing animal matter, and thus produced, it has been transmitted from one individual to another." (6)

Wallace, of Dublin, stated that he was convinced that no unprejudiced person can consider the subject without arriving at the opinion that the evi-

dence of introduction of venereal disease from Americas into Europe is quite inconclusive; that they have co-existed with the earliest era of human society, that in the Irish annals of an earlier date by many centuries than the discovery of America, mention is made of a disease by the name of *Bolgach Francach*, which signifies a French eruption of pustules, and this is the name by which the venereal disease is at present designated in Irish; that the pustular primary and secondary manifestations of syphilis are the original forms, and would in all probability have long ceased to exist if it had not been generated anew. He denied that the venereal disease had undergone changes in the course of centuries, but that "its nature is the same as it has ever been," and while admitting severity due to bad treatment he also demonstrated from clinical observation and inoculation experiments the modification of syphilis by transmission and propagation, and concluded that "the venereal poison is from time to time reproduced, and consequently that if all the venereal poison existing in the world was at this instant annihilated, the promiscuous intercourse of the sexes or other circumstances would quickly lead to its renewal" (7).

Erichsen and others have noted the absence of constitutional symptoms in the records of contagious ulcers arising from sexual intercourse previous to the descriptions of disease at the end of the fifteenth century, when it was looked upon as a new and previously unknown affection. "If it (syphilis) had previously existed in the Old World in a mild or modified form different from what we now observe, it is certain that about this time it suddenly assumed greater intensity, all its symptoms being aggravated in a remarkable and fearful manner, presenting characters which had not been previously alluded to, but which have often been reproduced in modern times; as, for instance, in those severe forms that were observed in the British armies during the Peninsular war, and according to Larrey, among the French troops during Napoleon's German campaigns."

The same aggravation of pre-existing modified syphilis may be adduced in the testimony regarding syphilis in China. It may of course have originally been introduced into this country, though it would appear that it had existed there from time immemorial, and "as if China had undergone for thousands of centuries a kind of general syphilisation which has progressively attenuated the virulence of the infection in the organisms affected by it." Nevertheless "the venereal affections contracted there by Europeans assume a character of acuteness and severity disproportioned to the symptoms experienced by the Chinese." (Armand).

I regret that I have no facts to record from my own personal observation in proof or disproof of the *de novo* origin of syphilis. At the same time, while admitting the alternative views of introduction and aggravation into fresh countries, and of reactivity of pre-existing modified syphilis in epidemic form, it seems to me impossible to ignore the impressions of passed authorities in favour of the *de novo* origin of syphilis in Europe at the end of the fifteenth century, and in later individual cases. At the present day, while entertaining the microbic theory of syphilis and transmission, there is not, as far as I know, any proof that such germs may not originate also in promiscuous intercourse, retained and decomposing seminal and genital secretions in the woman, or by admixture of different virus; that the virus of local disease may be aggravated into the infecting; or that non-pathogenic organisms in the parturient canal may become pathogenic. In the case of gonorrhœa I have elsewhere ventured to

express the doubt as to the acquisition by transmission of the gonococcus in certain cases in women. However speculative this may be, it is admitted in cases of vulvitis in female children and in pyosalpinx of virgins in which the gonococcus has been present, acquisition has not been demonstrated, but has been hypothetically assumed by extra-genital or genital transmission. "All contagions, all morbid poisons must have had an origin. We cannot presume that they have existed from the beginning; for, as Mr. Hunter observes, animals are not naturally formed with disease, or so as to run spontaneously into morbid actions, and it is not in opposition to the general laws of Nature to infer, that if a morbid poison has commenced at one period from the concatenation or combination of its essential causes, it may also commence in a similar way at other periods. On the contrary, such a supposition is in perfect unison with daily occurrence; for do not certain contagions frequently spring up, and again die away from combined causes whose mode of action we are not always able to appreciate?" (8)

Note.—Since the above was written it is interesting to find that in the case of a common cold Sir Douglas Powell, in his address in medicine at the British Medical Association meeting at Portsmouth, emphasises the conversion of quiescent pre-existing organisms into virulent and highly contagious "under the stimulus of a momentary chill at an open door or a wetting that would fail to affect us on the mountain side," and Dr. Burney Yeo on "Intestinal Antiseptics" notes that "the bacillus coli is a normal inhabitant of the intestine, and under ordinary circumstances is harmless." Under various conditions, however, it takes on virulent action.

ALCOHOLISM AND EVOLUTION.

By E. MACDOWEL COSGRAVE, M.D. Dub.,
F.R.C.P.I.,

Professor of Biology, R.C.S.I., President Irish Branch (Central)
British Medical Temperance Association

THE abstract of Dr. Reid's article on Alcoholism in Its Relation to Heredity," published in the *MEDICAL PRESS AND CIRCULAR*, of September 6th, displays a chain of argument apparently intended to inculcate a "let it slide" attitude towards intemperance, handing on its treatment and correction to the slow workings of evolution. The chain, however, seems to have weak links, and the object of this paper is to point out some of these weak spots. In order not to misrepresent the author, his paragraphs are given *verbatim*, but the points of criticism will be better appreciated if read with the entire abstract.

"Every drunkard has in his nature a marked capacity for enjoying alcohol, and in addition to this a keen memory of the delights conferred by previous acts of drinking. The primary capacity for enjoying alcohol is an inborn factor, and thus, in harmony with the teachings of biological theory, it may be transmitted. The other element, however—viz., the keen memory of the delights conferred by acts of drinking—is a later trait, an acquired character, and this cannot be transmitted to the offspring of the drunkard."

As a matter of common experience many people live for years taking alcohol in moderation because it is the custom to do so, without experiencing a marked capacity for enjoying it, and yet afterwards develop into drunkards. We see this often in the case of women who, when they get out of health, increase their *quantum* in order to shake off lassitude

and sickness; in doing so they often justify Sir B. W. Richardson's aphorism—"Those that rely on alcohol are lost." The keen memory of the delights conferred by previous acts of drinking is not as constant as Dr. Reid thinks; it is more often the awakening to unpleasant reality of aching head, sick stomach, and depressed nervous system that causes a craving for another dose of that which gives temporary oblivion to physical and psychical distress.

"Some men are abstainers or are temperate because their innate desire for drink is small or practically nil. Others, *per contra*, relish drink so greatly and crave it so greedily because, having once had experience of it, a very intense pleasure is felt and strong desire experienced. It is from the ranks of the latter that the army of drunkards is recruited. Between these two extremes are all shades of drinkers."

Here again is justification for temperance work: if the latter class are kept from having experience of it by being brought up abstainers, the strong desire will not be experienced. Again, in the intermediate group of all shades of drinkers are many who will gravitate to one or other extreme according as the strength of attraction varies. Drawing to the army of drunkards are the drinkshops, the drinking customs of society, &c.; is it not well that temperance organisations and counter-attractions should do a little pulling on the other end of the rope?

"This shows that the effects of intemperance as acquired by ancestors are not transmissible, for were it the case then the constant accumulation of such effects, generation after generation, would render the race that had longest used drink the most inclined to drunkenness."

Dr. Reid here neglects the automatic action which avoids this increased inclination to drunkenness; in this the sins of the fathers are visited on the children to the third and fourth generation—and no farther, for by that time the race has died out, and so by natural selection there is a constant reversion to a more sober type. It is, of course, a matter of common knowledge that the transmission of acquired characters is not proven, and so inebriety is probably not handed down; but as Dr. Sims Woodhead lately said, "The taste for alcohol is not transmitted, but the disposition to yield to its influence." The offspring of inebriates inherit weakened vitality and so are subject to vicious example, and when in sickness or sorrow they have recourse to alcohol, and find it gives temporary alleviation, they learn to rely on it, and easily become drunkards. This is not handing down an acquired tendency, but it is more than an acquired character.

"The temperance reformer's plan of abolishing drink is not the true method of reform. Were such a procedure to come into force for a time the result would be that the nation now removed from alcoholic selection would revert to the ancestral type in which the tendency to excessive drink was greater, and directly the opportunity recurred would drink almost to extinction, like savage man unacquainted in the past with alcohol."

This argument has often been brought against the attempts of sanitarians to prevent infectious diseases. Measles introduced by sailors has devastated the native population of islands on which it was previously unknown. We are trying to bring up our people free from measles. Sometime measles will be re-introduced and then it will devastate the population—such was the argument used, yet, in spite of it, sanitarians are labouring to prevent measles, and in spite of Dr. Reid's arguments, sanitarians will try to prevent drunkenness. If Dr. Reid's proposition is true, the way to get rid of small-pox would be to return to universal inoculation and so give evolution

the best chance of separating off a race for whom small-pox would hold no terror.

There is good reason to think that the reverse of this proposition holds good, and that abstinence from drink for some generations would lead to such an improved standard that intemperance would be less likely to follow the re-introduction of drink. Indeed, we have a proof of it if we take the individual as following out the history of his race; those who abstain until they come to the age of 20 or 30, comparatively seldom become drunkards. By Dr. Reid's theory, the tissues kept from alcoholic selection ought to show an increased tendency to drink to excess.

Another reason why an appeal to evolution is useless is that we have not only to deal with black and white, but with intermediate shades. If excess in drink killed, and all those that survived were healthy, there would be some grounds for a policy of non-interference; but some who drink more than is good for them do not die off, and have wives and families depending on them, and depending unsuccessfully, for the housing, feeding, and clothing necessary for healthy lives, so even when the drunkard dies, lives wrecked by drink remain.

Evolution has the further disadvantage of working for posterity and doing nothing for the men and women of our day; and though the exhaustion of the coalbeds and of the atmospheric air are important questions, we give them but languid interest, knowing that there is enough coal and air to last our time and to supply our younger friends. Temperance work has the decided advantage that, whilst it may trouble posterity and worry evolution, it certainly helps those of the present. The pressing questions are how are we to reclaim existing drunkards, how are we to stop the manufacture of new drunkards? Temperance workers may not be adopting the best plans, but they are the best they know, and they are much better than allowing the present evils to go on unchecked waiting for a far distant and problematical improvement.

INDICATIONS FOR CÆSAREAN SECTION AS COMPARED WITH THOSE FOR SYMPHYSIOTOMY, CRANIOTOMY, AND PREMATURE INDUCTION OF LABOUR.

By PROFESSOR LEOPOLD,

Dresden.

In the following paper, which was read at the International Congress of Obstetrics and Gynecology last month in Amsterdam, and furnished by "Our Own Correspondent," the author makes a very exact classification of the various degrees of pelvic deformity and distinguishes between the cases of primiparous and those of multiparous women. Three degrees of contraction ought to be distinguished:

1. The conjugata vera is more than 7 centimetres in the contracted nonrachitic or rachitic pelvis, more than $7\frac{1}{2}$ centimetres in the justo-minor pelvis.
2. The conjugata vera is less than $7-7\frac{1}{2}$ centimetres, but more than 6 centimetres.
3. The conjugata vera is less than 6 centimeters.

In the first group primiparæ generally have a tolerably good labour. The method of proceeding consists in preserving the membranes and waiting. The contraction in itself makes no demand on operative treatment. When the membranes are ruptured the colpeurynter may be introduced or the descent of the head may be facilitated by placing the woman in Walcher's position. With care and patience many useless and dangerous operations can be avoided. When the head does not enter the pelvic brim—perhaps on account of a bad presentation (the case

approaches the second group)—a distinction is to be made between cases treated in hospital and in private practice.

In the hospital, Prof. Leopold does not hesitate to perform the Cæsarean section when all other means have proved useless and *when mother and child are in good condition*. *When the child is in danger* he prefers craniotomy, certainly the only legitimate operation when the child is dead.

In home practice craniotomy is the only indicated operation when the head is retained by a pelvis too narrow to allow the passage of a living child. Though Pinard has given as his opinion that "craniotomy of the living child ought never to be performed" and that "embryotomy of the living child is condemned," Prof. Leopold, appreciating the ideal view taken by the celebrated French obstetrician, agrees with Charles (of Liège) "that it is not easy to act up to these rules." Doubtless the craniotomy of the living child ought to be avoided as much as possible, and an operation, inoffensive for the child, ought to take its place, but *in difficult cases in private practice*, craniotomy, which saves the mother, is preferable to Cæsarean section or to symphysiotomy, which give a considerable maternal mortality.

In the third group Cæsarean section alone is indicated, forceps and version being impossible, and the extraction of the child after perforation, even after symphysiotomy, being very difficult, if not counter-indicated. With *multiparæ* the difficulties of labour are greater because of the greater weight of the fetus and the lesser intensity of the contractions of the uterus and the abdominal walls.

In private practice the premature induction of labour, either by the bougie, or by the intra-uterine bag, is and will be the choice operation in the pelves of the first group, notwithstanding the brilliant results of Cæsarean section and of symphysiotomy. With the use of the bougie, the place of insertion of the placenta is to be taken into consideration. The converging or diverging of the Fallopian tubes and the round ligaments enables us to ascertain this place, and the bougie ought to be introduced in that uterine part which is opposite to the insertion of the placenta. During labour, rupture of the membranes has to be avoided and the descent of the head to be assisted, for in premature labour the prognosis of head-presentations is far better than that of other presentations. By the aid of Walcher's position the conjugata vera is widened from $\frac{1}{2}$ to 1 centimetre.

The results of premature labour are very satisfactory. Many obstetricians have noted from 60 to 80 per cent. living children, the mother leaving the hospital the eleventh day. In private practice the difficulty for the obstetrician is to determine the stage of pregnancy, the exact pelvic mensuration, and to obtain all that is necessary for the child (converse, nurse, &c.). A good deal of the bad results are due to such precautions being neglected. When the accoucheur is called and labour has begun with a multipara of the first group, above all things rupture of the membranes must be prevented, the colpeurynter must be introduced, and then wait for complete dilatation. If at that moment the membranes are intact, Prof. Leopold prefers the podic version followed by the extraction, facilitated by the enlargement obtained by Walcher's position. Although by the aid of complete narcosis, version is not impossible some hours after the rupture of the membranes, the results for the child are still a good deal less favourable, the difficulty or even the impossibility of version necessitating often dangerous operations.

In the pelves of the second group craniotomy should be performed when the child is dead. Prof. Leopold prefers also craniotomy to the other operations when the child is in danger

or the mother exhausted or ill. When the child is in good condition, Cæsarean section or symphysiotomy can be done in *hospital practice* (personally Leopold prefers the first operation).

In *private practice* these two operations may be, now and then, preferred to craniotomy, when the obstetrician is very skilful, and has sufficient assistance, and when the woman is in very good condition. In the third class of pelvis, Cæsarean section is the only operation indicated, alike for primi or multiparæ, symphysiotomy being forbidden by the excessive contraction of the pelvis.

CONCLUSIONS.

I. *Before term*.—When there has been one or more difficult labours caused by pelvic deformity, premature induction of labour is indicated when the pelvis is not too much contracted (conjugata vera more than 7 centimetres in flattened pelvis, more than 7½ centimetres in the justo minor pelvis). The best moment for intervention is the thirty-fifth week of pregnancy. Good results are not to be expected unless the membranes remain intact and there is a head-presentation.

II. *At term*.—Craniotomy is indicated: a. When the child is *dead* and labour does not advance, even when the pelvis is only slightly contracted. b. When the child is in *danger*, the contracted pelvis being an obstacle for spontaneous birth, forceps and version being too dangerous or impossible. This rule is valuable equally for hospital and home practice. The danger for the mother is too great to risk Cæsarian section or symphysiotomy when it is not quite sure that a living child will be born. c. When the child is in *perfect condition*, craniotomy will be performed only as an exception in hospital practice. But in private practice it is indicated when spontaneous birth, forceps and version are excluded and the termination of labour is necessary, the obstetrician, all circumstances duly considered, regarding Cæsarean section or symphysiotomy too dangerous. The conjugata vera must be more than 6 centimetres.

In exceptional cases, when for private reasons it is important that the child is born living, should it be only for some minutes, the advice of a colleague is to be asked and the family of the woman is to be acquainted with all the dangers accompanying the operations by which the child can be saved.

The *Cæsarean section* has absolute or relative indications. In pelvis with a conjugata vera of 7½—6 centimetres the indication is a relative one. When this diameter is less than 6 centimetres the indication is an absolute one. Cæsarean section on relative indications requires the fulfilment of the following conditions: a spontaneous birth being impossible, forceps and version inadmissible, the child in *perfect condition*, and the woman either in a hospital or in circumstances quite as favourable as to the operation itself and as to subsequent nursing.

When the circumstances are not favourable enough, craniotomy of the living child is to be preferred.

Symphysiotomy is only indicated in pelvis with a conjugata vera of 7½ to 6½ centimetres; the indications are therefore much more limited than those of Cæsarean section and do not all regard the pelvis of the second class. With this restriction symphysiotomy may compete with Cæsarean section on relative indication, and requires the same conditions. When these conditions are not fulfilled, craniotomy must be performed.

The choice between symphysiotomy and Cæsarean section as relative indication depends on the experience of the operator. The results of both operations, performed under the same conditions, are almost equal for the mother as well as for the child.

MONISTIC PHYSIOLOGY.

By W. R. MACDERMOTT, M.B.,

Poyntz Pass, Newry.

"A KNOWLEDGE of Nature—more exactly scientific knowledge or knowledge of the physical world with the help and in the sense of theoretical natural science—is the reduction of changes in matter to the motions of atoms, motions effected by the intrinsic forces of the atoms independent of time or otherwise, the resolution of natural events into the mechanics of atoms."

By a coincidence in the mechanics of cerebral atoms, this passage from du Bois Reymond's address, "Ueber die Grenzen des Naturerkennens," is not only quoted, but made the text of two recent works, Prof. O. Hertwig's "Mechanik und Biologie," and Prof. Verworn's "General Physiology." (a) The last, which I only know from Prof. Lee's translation, strikes me as of interest to us as showing the lines on which medical science must go in future, in detail at least. For instance, of what significance to us must appear the experiments of Demoor, which show that while the protoplasm of the cell is paralysed by chloroform narcosis the movements and functions of the nucleus appear undisturbed, and yet the nucleus is held by some to be the brain or regulative organ of the cell. The book abounds all through with facts and reasonings like this of immediate bearing in medicine.

It is well that general physiology and therefore medicine has a nucleus which somehow escapes the theory narcosis to which its environment is susceptible. It is Prof. Verworn's argument in his earlier pages that physiology is paralysed by the mechanical theory of which he takes du Bois Reymond as the exponent, an author who writes not only *ignoramus* but *ignorabimus* against the question of vital economy. If the reader skipped these earlier pages and read the technical part, the bulk of the book, he would find that Prof. Verworn systematically explains all vital phenomena by known mechanical principles, leaving no place for proper mental operation in the cell or organism. He would be at a loss in such case to distinguish the issue between his author and du Bois Reymond, or if he did recognise it might, irreverently, perhaps, underestimate its importance. One of these writers, Verworn, is alive, and, *Hibernice*, I cannot resist the opportunity of wishing him a long life; but he is evidently a skilled thinker and dialectician, and I dare much to paraphrase his meaning. Nevertheless, brevity compels me to do so, referring the reader to his book for his own words.

In du Bois Reymond's view, the cell organism or any physical item is taken as a real thing in itself, the operations in which it plays a part being independent of the operation whereby we know them, which is another real thing in itself. From Professor Verworn's standpoint, on the contrary, the only real thing is the thing as we know it, subject to the conditions of knowing, is an idea. "Beyond my own mind I cannot go. My own individuality, indeed, is only an idea of my mind, and therefore I cannot finally say the world is my idea, but I must say the world is an idea, or a sum of ideas, and what appears to me as my individuality is only a part of this complex of ideas, just as is the individuality of other men and the whole physical world."

In one view the physical world, or, to take a particular, a man's physical being, determines the idea of that being which otherwise would not even occur to us. Without an objective ontological base an

(a) "General Physiology." By Max Verworn, M.D., Ph.D. London: Macmillan. 1896.

ideal base in ourselves would give no representation. There are many forms of this opinion, one of which, monistic materialism, i.e., where consciousness is taken as the product of the physical base, is popularly thought to be the settled creed of medical men. Our attitude, however, is one of eclectic agnosticism, that of innocent lambs who do not think of the thing at all. There are reasons, however, as I shall end by showing, tending to force us to forego that easy-going attitude. What from Prof. Verworn's view is the meaning of physiology, the base of medical science? It is an ideal science valid only as such, its statements purely mental and expressing truth, reality, causality, through the condition only of mental operation, the operation of my own mind which I cannot go beyond.

What I think about in physiology, he may be taken as saying, are the contents of my own mind in which alone the idea of connection, causality, interaction exists. "The idea of the physical world is only a product of the mind, and with the alteration of an old sentence of the sensualists, it can be said: *Nihil est in universo quod non antea fuerit in intellectu*." Our problem "consists not in explaining psychical by physical phenomena, but rather in reducing to its psychical elements physical like all other psychical phenomena. Every process of knowledge, including scientific knowledge, is merely a psychical event; science deals with metaphysics as in accordance with an ancient and unfortunate manner of expression it is customary to term it, and science cannot exist without metaphysics. This fact cannot be banished by the method of the ostrich." Again, "the sole reality is our mind and all phenomena are only its contents; explanation, therefore, consists simply in the reduction of all psychical phenomena to their elements. In this sense all science, and, in general, all knowledge, is in the end psychology. We thus come to the only consistent standpoint, monism, the unitary view of the world, which seeks to derive all phenomena from a single cause."

The proof of all this is rested on the statement that we have created our knowledge of the physical world by sense-perception. "This is clearest in persons who are born blind and have built up their physical world through hearing, touch, &c." When made to see by a surgical operation they do not recognise an object known by touch, a ball for instance seems something quite new, and only when they touch it do they realise its identity. "At that moment a new world begins to rise in them."

I have given Prof. Verworn a fair half of the space I can take, not enough indeed, but must reserve the remainder for what will occur to men who want some base for the study of what is called mental disease. If only because we see a man's own mind so often in an abnormal state, so prone to aberration, weakness, and decided disease we would hesitate to take it in a rigidly individualised sense as the single self-sufficient source of causal law and governing power. Like most men who think at all, we sum ourselves as creatures, if not playthings, of circumstance, and assign to the individual mind the subordinate function of metabolism—accommodation from instant to instant to a play of circumstance in general beyond it. The circumstances under which individual minds act, and the capacities of accommodation of these minds to circumstance are so variable that we habitually reject the individual mind, the mental atom, as the essential element in thought. When Professor Verworn speaks of the contents of the individual mind, we think of an empty vessel, with a peculiar shape and capacity of its own, which determines what it will hold and how it will hold it, but its contents are put into it. This does not quite mean Locke's

sheet of white paper, but it does mean that we have no right to reason about the contents of our mind as its own product and property. Farther while some small part of our ideas come into our minds as air into our lungs a large part of them we would say come to us not from single minds but as the elaborated product of a series of minds. The evolutionist would generalise this statement so as to include a pre-mental stage, and, if not a psychomist of Professor Verworn's type, of distinctly physical nature. Again we practically hold in our professional view that mental health depends on mental metabolism, on the stream of incoming impressions and ideas being assimilated, and dissimilated to use the terms we find here, in which process we believe that the ingested materials often prove to individual minds undigestible or poisonous, and are often rejected as Professor Verworn rejects the ideas of du Bois Reymond's school.

As the contents of the individual mind are foreign in bulk to it as mind so the contents of each separate idea are foreign to it as idea. Reasoning from idea as idea *per se* is obviously invalid. An idea must be an idea of something, and for fundamental ideas we cannot go beyond what each affirms in mind as its something. If idea affirms itself of idea, of mind, we must accept its affirmation, and when it affirms itself of not-idea, not-mind, we must equally accept the affirmation. An idea separated from what it is an idea of, is incomprehensible to us, and denying its affirmation on the grounds that it is mental invalidates all mental determinations. The conception of idea apart from object on which Prof. Verworn rests is a conception which has no place in the contents of mind. But since idea affirms itself of idea as object we really have ideal science, a science of ideal objects. Prof. Verworn cites mathematics, but mathematics is only a branch of the science of language, of expression of idea. In language, perfectly arbitrary symbols are assigned to ideas, but just because these symbols are common to numbers of men assigning the same meaning to them, they evidently compel numbers to think in the same way, that is, collectively, not individually. It is language, including mathematical or arithmetical language, that supplies the bulk of the contents of individual minds. A man thus cannot take idea apart from object, and, unable to claim ownership of the contents of his own mind, he must go behind his own mind and inquire where they came from.

From sense-perception. That only means that the vessel is empty, and has capacity for holding what is poured into it—or not holding it. Most of us would say that without sense-perception we would have no knowledge, and with it alone we would still have none. Our mental, like our bodily, food has to undergo an organic process outside, and independent of us, before we can assimilate it.

My fragment of criticism of Professor Verworn's psycho-monism must conclude with the objection that it is in opposition to our views of the nature and treatment of insanity. We hold that a man not only can but does habitually go beyond his own mind, can and does correct mental error arising through defect in his organisation. The simplest illustration is where he wears spectacles to correct imperfect sight, but it is the same when he takes counsel with friends and submits his mind to theirs. He might be weak-minded if he carried this too far, but he would be insane if the mind and judgment of others had no value or weight with him. The insane treat themselves—for they often treat and cure themselves—by acting on this principle of realising and deferring to the mind of others and to the force of circumstance. We should allow no theory to obscure a principle of such utility.

This leads to another position which I think we would stick to. The true response of healthy mind to disease is recognition, representation of the disease. When a man is mad there is true mental representation of a disordered physical state; his mind would really be mad if it gave the normal response. A person colour-blind is mentally sane exactly because he is colour-blind; a madman suffering from rapid succession of incoherent ideas is sane from the point of view that his mind truly represents a state of object, a cerebral storm. Many of us would hesitate to accept this purely dualistic conception of mind and body, though the observation of the phenomena of compensation in injury and disease of the brain is forcing us to adopt it. For my part I believe our ultimate position shall be that there is immediate presentation of all physical state in mind, and not merely mediate presentation through nerve state; the last I take, as much dead object to mind as a telegraphic system, deriving its mental importance from its value as bodily function.

But practically we allow no theory, and should allow none to obscure the distinct and useful impression that we are dealing with two separate factors in a patient, one physical the other mental state, each of which can be controlled or influenced separately. When bodily disease exists, fortunately as a rule there is not only true but conscious representation of it as disease, and in the case of cure mental effort directed to that end. The number of the insane would be vastly greater than it is if there was not a general perception of mental unsoundness due to personal organisation, and a capacity to travel beyond one's own mind to correct it. This mental ability and effort to transcend personal mind as function of organisation is at the bottom of more than medicine.

Farther we act on the belief that the physical factor is capable of control by our minds operating through physical means, means which usually operate unconsciously to us. We cure ourselves as we warm ourselves, not by ideal operation in our own minds, but by idea of physical circumstance directed to command the object by physical means. One may be impatient at such an argument as trivial, but the impatience should be with the occasion for it, a challenge to our practical philosophy.

Hugh Miller, in "Schools and Schoolmasters," tells a story of an imbecile fond of snuff to whom mischievous boys used to give a little in a small deep can. The imbecile would spend hours trying to get at the snuff without the idea ever occurring to him of turning the vessel upside down. We have here perfect sense perception of object as actually presented, but not ideation, which comprehends states of object contingent and possible though not presented. When out of the stores of a richly furnished mind Prof. Verworn displays before us the heritage of thought, it is to be remembered that those who accumulated it acted on the belief that a natural field existed in which idea and object are distinct yet inseparable, and that the object in reaction necessarily forms the idea. The doctrine of psychonism which challenges that historical base of knowledge, I think, easily accounts for the imbecile, but only by a strained and supremely difficult interpretation for Prof. Verworn.

OUT-DOOR TREATMENT OF TUBERCULOSIS IN LARGE CITIES.

By DAVID SOMMERVILLE, B.A., M.D., B.Ch.

THE fruits borne by the modern treatment of tuberculosis warrant the most persevering attention on the part of the physician, in a large number of cases formerly left to perish. Almost daily we hear

of the remarkable and lasting effects of the out-door cure. This cure in essence consists in placing the patient under conditions in which his vital forces are so increased that his tissues are enabled to successfully battle with the disease—in short, it is a system of overfeeding, coupled with an out-door life, in an atmosphere possessing to the greatest degrees rarity, dryness, and sunshine.

That some of the Continental sanatoria possess advantages unattainable in England there is no denying. Their atmosphere is rarer, dryer, and they enjoy a larger share of sunlight. The rarity of the atmosphere compels an increased action of the lungs in inspiration; the diminished proportion of oxygen must be compensated by a larger intake of air. Perhaps the chief advantage of most of the elevated sanatoria is that they enjoy so much sunlight, a factor in the life of the organism of the first importance.

That this treatment can be successfully carried out in England is being slowly demonstrated, and even London, when occasion requires it, can become a sanatorium. A case that came under my care recently, adds to the mass of growing testimony in this direction.

A young man, H. N., æt. 21, a native of Germany, was sent to London to acquire English and a knowledge of the routine of an English business house. I saw him in the beginning of April last. He had then been suffering for more than three months from repeated "colds." He had always had a weak chest, and his throat "gave him trouble." He was emaciated, weak, and appeared to the most casual observer quite ill.

On examination, his chest presented typical characters of tuberculosis of the lungs. The supra- and infra-clavicular regions were hollow; vesicular murmur at right apex was replaced by fine râles; signs of consolidation were apparent for some little distance downwards and inwards from the mid point of the clavicle on this side. Râles were not heard at the left apex, but inspiration was ill-defined and of the cog-wheel variety. Expiration was much prolonged. Sputum was abundant, nummular, streaked with blood, and a bacteriological examination showed numerous tubercle bacilli. Hæmoptysis at this date was marked. The pharynx presented a dark-red congested appearance, relieved here and there by pale patches. The larynx partook of this congestion to a considerable degree, the arytenoid folds and mucous membrane in the neighbourhood of the posterior ends of the vocal cords exhibiting the same swollen mottled appearance. When we add to this that an evening temperature was found elevated to the extent of $1\frac{1}{2}$ to 2 degs. F., there is no doubt as to the nature of the malady. The pulse was rapid, weak, and very compressible, average rate 110, but at times very rapid; on two occasions in the first week of observation it was found to be 125 and 132 respectively.

My first thought was to send him at once to Nordrach, and accordingly I wrote to his family physician in Hamburg recommending this course. Circumstances prevented his going then, so the next best thing to do was to work out the Nordrach treatment in London. In charge of a most capable lady friend, who devoted her entire time to his care, he forthwith commenced his new life. The daily round consisted of one or two short walks in the open air, a certain amount of driving, according to the condition of the weather, a rest for half an hour, or longer before each principal meal, with a superabundance of easily digested nourishing food.

Two points struck me in the progress of this case: At first the patient had a very poor appetite and resented additional food. But on having it plainly put to him that his life depended on his eating, he struggled with his meals, and as the quantities of

various food stuffs eaten increased, the appetite and digestive ability progressed in like ratio, until in a few weeks he was digesting well, five pints of milk, five or six eggs, two large meat meals with milk pudding, and a number of minor dishes, daily. The second point is that his circulation improved at a rate beyond all expectation. Pulse-rate came down to 80, with a corresponding increase in strength, the dyspnoea that attended at first any little muscular effort entirely disappeared, and by the end of the fifth week he had exchanged a condition of great muscular debility for one of considerable force.

At the end of seven weeks a second bacteriological examination demonstrated the entire absence of tubercle bacilli, and the presence of only a few micrococci. The sputum had greatly diminished in quantity; the apical râles had completely disappeared, and the supra- and infra-clavicular hollows were filling up. The breath sounds were now distinctly audible in these localities, and when he returned to Hamburg at the end of the first week of June, there was very little abnormality to be detected on either side of the chest. He had at this date put on 15 lbs. in weight.

Comparing this case with others sent to Nordrach I am of opinion that the way in which his friend managed him in London, in ordering his outdoor excursions, each with an object, in seeing that daily the necessary quantity of food was partaken of, and generally so taking him out of himself that his time passed in somewhat holiday fashion, conduced more to his rapid recovery than a corresponding stay at a sanatorium could have done, especially as he held such places in disgust from experience previously had at a noted resort on the Continent. And this leads to the idea that there may be many cases which would do much better under such separate and agreeable conditions, than amidst the depressing influences of a multitude of others in the same condemnation at a sanatorium.

A somewhat corresponding case in a lady has just come under my notice, where practically the same course is being pursued with results that promise to be quite as successful.

Clinical Records.

A CASE OF GUNSHOT WOUND OF THE LEG SEVERING THE ANTERIOR TIBIAL NERVE. —SECONDARY SUTURING TWO MONTHS LATER.—RESTORATION OF FUNCTION OF NERVE.

By PHILIP R. W. DE SANTI, F.R.C.S.,
Senior Assistant Surgeon and Aural Surgeon to Westminster
Hospital.

AN officer of the Indian Staff Corps was on April 8th, 1898, wounded in the battle of Atbara. The bullet penetrated the outer side of the left leg at the level of the upper one-third of the fibula; about two inches of this bone were splintered. The bullet then travelled downwards between the tibia and fibula, and emerged about two and a half inches below the centre of the popliteal space.

He was treated by Captains Spong and Dunn, of the R.A.M.C., and though there was considerable laceration of the calf muscles and splintering of the fibula, did very well.

In June, 1898, I saw him at St. Thomas' Home, and found the apertures of entry and exit of the bullet open and discharging pus. There was complete paralysis of the muscles supplied by the anterior tibial nerve and marked reaction of degeneration. Dr. Turney made a careful electrical examination of the limb and confirmed the state of affairs. The ext. cutaneous (peroneal)

nerve was intact; sensation but little impaired. I advise exploratory operation, and on June 10th Captains Spong and Dunn being present as well as Mr. Edmunds and my house surgeon, Mr. Evans, cut down on the outer side of the thigh and leg, exposing tendon of biceps and external popliteal nerve; this latter I carefully dissected downwards to wound scar where it became thickened, adherent, and embedded in dense cicatricial tissue. With difficulty I freed it, and found it partly bulbous; the external musculo-cutaneous was intact.

I next cut down on the interval between the tibialis anticus and ext. longus digitorum, and found end of ant. tibial nerve; this was difficult to make out and very atrophied. There was a considerable interval between the proximal and distal ends of the divided nerve; but by stretching of the external popliteal and flexion of the knee, I was able to bring the two ends together. After freshening them up, I united them with two chromicised catgut sutures passed through the substance of the nerve ends. The wound was entirely closed and healed up by first intention. The limb was kept on a Macintyre's splint. On June 13th massage was commenced. July 18th he was up and about on crutches: Daily massage and galvanism; affected muscles seem fuller, and limb is not so cold as it was.

August 3rd., 1898.—Dr. Turney reported. "The electrical examination I have just made is extremely satisfactory. The ant. tibial muscles react to the Faradic current, and though the contraction is sluggish and requires a larger current than normal, this is a great advance. To the galvanic current there are still signs of degeneration, and the contraction is notably sluggish. I think that complete recovery of function will eventually occur."

October 3rd, 1898.—Excellent development of muscle; is able to walk with aid of one stick. Owing to laceration and matting of calf muscles, not able to quite straighten the knee.

March 6th, 1899.—Dr. Turney reported:—"I have just examined Major H.— electrically, and am glad to be able to give a satisfactory report. The anterior tibial muscles react to a strong Faradic current, and much more briskly than they have done hitherto. Although there is no appearance yet of voluntary power, still there is no doubt that function is present potentially both in nerve and muscle, and it is only a matter of time when this becomes apparent."

July, 1899.—A still further improvement. Rides his horse, and also bicycles. He is still continuing massage and occasional galvanism.

France.

PARIS, September 17th, 1899.

FISSURES OF THE ANUS.

FISSURE of the anus is, as everyone knows, an affection as troublesome as it is painful. Of the different remedies recommended, forcible dilatation of the sphincter is the most radical and perhaps the most effectual. But it is not easy to get the patient to submit to the operation outside of hospital practice. Dr. Boas recommends a much simpler treatment, which he affirms to have succeeded with him ten times out of twelve. The principle of the treatment being the complete immobilisation of the anal region, he puts the patient to bed for one week, allowing for all nourishment, milk and light potage.

At the same time he orders ten drops of laudanum to be given three times a day, so as to produce absolute constipation. If the fissure can be brought to view he powders it with iodoform, calomel, &c., but without touching it with any instrument or dressing. Any antiseptic washing would be more hurtful than useful. At the end of eight days he

administers a full dose of castor oil, recommending the patient to restrain himself from defecation until he felt that the contents of the intestine had become completely liquid. The treatment only failed where complete retention of the feces could not be obtained.

ABSCESS OF BARTHOLIN'S GLAND.

M. Jullien, of the Saint Lazare Hospital, treats abscesses of the vulvo-vaginal gland by injections after the evacuation of the pus of two or three drops of a solution of chloride of zinc (1-10) into the gland by means of an ordinary hypodermic syringe. Immediately after the injection and for some days intense inflammation sets in, but gradually subsides, and some time afterwards a small hard, but painless tumour, is felt through the soft parts. No relapse has ever occurred after this treatment.

CONGENITAL ABSENCE OF THE FEMURS.

A *confrère* reports an interesting case of congenital absence of the femurs in a child of seven months. Examination showed that the pelvis was perfectly normal, but both femurs were absent as well as the patellæ. The legs were composed of only one bone lying on the pelvis. Abduction and adduction were limited, and rotation was almost abolished; the fifth toe of each foot was also absent. Several surgeons proposed to remedy the malformation by operative intervention, and notably by the creation of an artificial articulation.

TREATMENT OF DROPSY.

Physiological experiments have shown that the diuretic action of caffeine is notably increased by the addition of certain hypnotics, and especially of chloral or paraldehyde. In renal or hepatic disease the association of hydrate of chloral at the dose of twenty grains with twelve grains of caffeine daily, the oedema and anasarca disappear much more rapidly than when the caffeine is given alone. In the case of cardiac dropsy, paraldehyde should be preferred, on account of the depressing effect of chloral on the heart.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, September 16th, 1899.

THE TREATMENT OF ULCERS OF THE LEG.

THE *Therapeut. Monatsch.* contains an article by Dr. Cipriani on this subject, the aim of which is mainly practical. By the method of treatment proposed four objects are to be gained:—1. Diminution of the pain; 2. Decrease in the size of the ulcer; 3. Convenience for both attendant and patient; 4. Cleanliness and rationality. The technique demands almost always six stages:—1. Careful washing of the limb with hot water; 2. Mopping dry with iodoform gauze; 3. The use of eka-iodoform which is lightly dusted over the ulcer; 4. Bandaging of the leg from the knee to the ankle with strips of linen, four or five layers one over another, lightly pressed out after being dipped in a solution of formaline 1 to 2 per cent. in strength, according to the constitution of the patient; 5. Further application of linen strips, dipped in a 2 to 4 per cent. solution of formaline and well wrung out; 6. A well-applied bandage. This procedure is to be repeated every twenty-four hours.

With this dressing the author has seen rapid healing of extensive ulcers of the leg. Even on the second day the purulent secretion ceased, also the pain and the foul smell. Large ulcers that had to a large extent destroyed the skin, cicatrised rapidly, as new skin spread quickly from small patches of epidermis that had remained. Even when these patches of epithelium were absent, and the skin of the margin showed no tendency to spread inwards, the first step of the treatment must consist of lengthened warm baths, which should be followed by careful curettement. This operation will not be painful, as the hardened and cicatrised tissue will have become softened by the prolonged bathing. In this way the edges of the ulcer lose their redness, the swelling of the adjoining parts subsides, and the absorbent power of the vessels is regained, the swollen veins empty themselves, stasis is diminished, and with it its accompanying morbid changes. The treatment allows the patient to go about his work, and in addition to this advantage it has a softening solvent action. The dressing remains moist long enough, and it exercises an absorbent antiseptic, soothing, and refreshing influence. Eczema or dermatitis, sometimes seen after prolonged use of iodoform, never appears; this is attributed by the author to the use of eka-iodoform.

INFECTIOUS INFLAMMATION OF THE LUNGS AND PSITTACOSIS.

In the *Col. f. Allg. Gesundheitspflege*, Prof. Leichtenstern, of Cologne, discusses this subject. The etiology of the infectious atypical pneumonia is in many respects doubtful. Psittacosis is a name specially given to that form of atypical pneumonia which can be traced back to a sick parrot. The subject is of the greater interest as it is one that has not been extensively studied in Europe. Psittacosis epidemics have been known in France and Switzerland, and more lately observations have been made on atypical pneumonia and similar forms of disease in Köln, Crefeld, Berlin, and Essen a Ruhr. The observations made by the writer himself and a consideration of those of others have led him to draw certain conclusions on the subject. No certain evidence has been yet adduced that psittacosis diseases are attributable to sick parrots. Parrots might under certain conditions be dangerous to human beings by microbes setting up diseases, especially forms of enteritis. Psittacosis is an atypical pneumonia with typhoid symptoms. This arises without any intervention of parrots. Epidermological facts, however, are in favour of the possibility of the disease being transferred to man by parrots. The prophylaxis consists in personal protection, and in the control of supervision of bird shops.

FRACTURE OF THE LARYNX.

The *Deutsch Med. Zeit.*, 72/99, reports a case of this rather rare injury. A girl, æt. 10, was kicked in the front of the neck by a cow. The surgeon who saw the patient shortly after the occurrence found her conscious she could still speak and cry out, but with an altered voice. On the anterior surface of the neck, corresponding to the middle of the thyroid cartilage, was a transverse erosion of the skin, one ctm. in length, and 0.2 to 0.5 in breadth. There was superficial emphysema of the face, neck, and upper part of the breast, and over both shoulders. Death took place in half an hour. Shortly before this took place, the emphysema spread over the

whole of the body, even to the tips of the toes. On palpitation of the larynx after death—before death this was not possible—a sensation of grating was felt, and gliding of one part over another. No post-mortem examination was made.

"WHEN SHOULD PATIENTS WITH GALL-STONES BE OPERATED ON?"

is the title of a *brochure* lately published by Dr. Fieck, of the Kaiser Franz Joseph Hospital, Carlsbad. The author has operated himself on 12 cases, and on the basis of the conditions found, as well as his observation over large numbers of cases not operated on, he endeavours to arrive at a conclusion as to the best time for operating. His conclusions are embraced in the following: If the inflammation accompanying the attacks of colic does not subside, if high fever sets in, if pericholecystitis comes on, or dropsy of the gall-bladder indicating closure of the ductus choledochus, then operation must be resorted to. If the inflammatory symptoms subside, surgical aid is not called for except in case of closure of the duct, or when troubles are caused by adhesion to the neighbouring organs.

QUICKSILVER AND GOUT.

The *Deutsch Med. Zeit.*, 71/99, has a short reference to a case of gout affecting the hand, under treatment by Professor Rindfleisch. Massage had been applied for several weeks without the production of any noticeable benefit. The professor then determined to make use of raw quicksilver locally. A glass wide enough to admit the hand, and sufficiently deep, was filled to two-thirds of its capacity with raw mercury. The patient's hand was then inserted slowly and kept in as long as the pressure of the mercury allowed. A considerable and equable pressure was felt as the fluid pressed with equal force on every part of the surface. The hand was placed in the mercury 20 to 30 times at one sitting, and at the close of the second a considerable diminution in the size of the hand was observed. In four days of this treatment, the joint was practically restored to its normal form.

THE TREATMENT OF ANTHRAX.

The same journal gives a note on the popular treatment of anthrax in Russia. Clean washed raisins, a few drops of distilled water, and sal ammoniac are triturated together to the consistence of honey, the ammonia forming about a fifth part of the whole mass. This is thickly spread on clean linen dusted with sal ammoniac, and placed over the abscess, care being taken that the whole inflamed circumference is also covered with the plaster; over this is placed lint and bandage. The dressing is renewed twice daily. Twenty cases of anthrax were treated in this way, in some both the local and general infection being very severe. All the cases recovered, and in no case was any other kind of medicinal treatment made use of.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, September 16th, 1899.

DEGENERATIVE CHANGES IN INJURED NERVES.

It has long been established in theory that the central part of a motor nerve undergoes degenerative changes when it is severed or separated by disease from

its centre. Sensory degeneration is found on the opposite side of the lesion, and has been termed ascending, while the opposite is descending.

In mixed nerves one would expect the analogy to hold good, but here the theory is disputed.

Elzholtz has by experiments demonstrated that peripheral nerves of a mixed character when wounded or separated from their central connection tend to degenerate towards the centre, causing atrophy of the ganglionic cell itself.

The nerve fibres of the afferent nerve are quite entire microscopically, but their function is lost, which Elzholtz compares to that met with in cachexia. He relates a severe case of gangrene, where the central nerves, when examined, were comparable to an animal's which had had a part of the ischiadic nerve removed a short time before death. In both were found corpuscular bodies about the size of small leucocytes, which when coloured by Marchi's process in Osmium, gave a dark colour, and could be easily recognised from the surroundings, lying between the sheath of Schwann and the cortical substance; sometimes, however, in Ranvier's nodules, at other times in Schwann's sheath itself. These bodies accumulate in the central part of the nerve, forty-eight hours after the lesion.

Thirty days later these bodies are so transformed into a fatty condition that they are quite unrecognisable.

PICA CHLOROTICA.

Cipriani records two cases of patients suffering from obstinate chlorosis, at. 12 and 23 respectively, who had been retained in an institution for some time under large doses of iron in the form of "Töpperthon;" 7 grams were given at first, gradually rising to a 100 grams, without any beneficial effect, while the digestive organs were seriously impaired by the treatment. He commenced somatose of iron in 6 gram doses, increasing to 15 grams per day, with wonderful results, menstrual and nervous symptoms quite recovering in a few months.

CYSTINURIA.

Cohn relates a case of cystinuria of a hereditary nature. About the beginning of 1897 a girl was handed over to him from the surgical ward, where she had been for some time under treatment for a tuberculous knee joint which had ultimately to be operated on. Shortly after recovery from the operation she suffered severely from pain in passing water. An examination of the bladder revealed a stone, which was removed. It was about the size of a walnut, angular, of a yellow-gray colour, and consisted of cystin. Other ten members of the same family had the urine examined for cystin, which was present in seven and absent in three.

Schwarsensky related a similar condition in a family, one of the members having been operated on for calculi which was cystinic in character. He believed this to be a hereditary characteristic.

Wolff said these were difficult stones to diagnose by the Röntgen rays.

"UNIVERSAL" COLOURING AGENT FOR BLOOD PREPARATIONS.

Michaeli's "Universal Method" for colouring blood seems to meet with general approbation, although some think there is very little advantage to be gained. The method may be briefly expressed by saying there are first two primary agents kept in solution, A and B. A is a one per cent. watery solution of chemically pure crystals

of methylen blue. B is also a one per cent. watery solution of eosin.

From these solutions another mixture is made immediately before use. Of A, 20 grammes are added to 20 grammes of absolute alcohol; of B, 12 grammes are added to 28 grammes of acetone (sp. gr. 56-58); the two well mixed.

The blood preparation which may have been twenty-four hours in absolute alcohol or exposed to Ehrlich's copper plate fixing is now placed in Michaeli's mixture for one to ten minutes, or till the red colour has changed to a blue. A successful preparation will give extensive colouring of the nucleus, neutrophile eosinophile, basophile granulations, and blood platelets.

REMOVAL OF LENS IN MYOPIA.

Velhagen records the results of fourteen cases he has operated on for a high state of myopia. In three cases the vision remained the same after the operation as before it, in other three it improved one and a half, in two cases it doubled itself, in two it tripled, once quadrupled, and once increased fivefold.

He thinks the removal of the lens should be carefully considered before operating, as it is disappointing. If the myopia can be alleviated by the assistance of glasses, so that the patient is enabled to perform his duty daily with anything like comfort, the lens should not be extracted.

Special Article.

THE LATEST CONCERNING BUBONIC PLAGUE IN SOUTHERN EUROPE.

We learn from *El Siglo Médico* that Dr. D. Carlos de Vicente, has arrived in Madrid from a sojourn in Oporto and Lisbon, where, as is known, he was commissioned by the Spanish Government to study the bubonic plague in Portugal. He has given his report to the Sanitary Director-General, and frankly his opinions are not optimistic.

Since August 18th the plague has greatly spread. It has assumed the pneumonic form, the most serious type. Added to this the Portuguese Government provides only the feeblest and least promising methods of sanitation. As a consequence of persons leaving the infected districts the disease is carried into distant parts.

Dr. Mendoza warns the Government that the plague owes its virulence to the filthy dwellings and habits of the people living in the poorer parts of the city. Those attacked are conveyed to the Misericordia Hospital, and none of the hospital patients were found to constitute new foci for disease, demonstrating the facility with which the epidemic might be localised and stamped out if energetic measures were adopted. Dr. Mendoza had micro-photographs of the plague bacilli taken.

Dr. Cortezo, director of the Sanitary Department of Spain, has appointed Dr. Ramon Cajal to the direction of the Central Institute of Serotherapy. The serum for the treatment of the bubonic plague is to be manufactured in the Central Institute, and its production in any other institution is strictly prohibited.

A Royal decree orders vessels coming into any Spanish ports from Lorenzo Marquez or Saint Denis to be quarantined.

Dr. D. Vicente Leorente has been commissioned to go

to Paris for the purpose of studying the production of serum toxins and their use.

The precautions adopted in Madrid are:—

The staff of permanent inspectors of goods at each station is to be increased by two; five extra inspectors for each station are also nominated, and are to be called on should urgency demand their services.

Lazarillos, for the examination of flocks or herds coming for slaughter from Portugal, are to be organised. All goods that have passed the frontier are to be carefully examined. Byres to be frequently visited, the stalls of cattle inspected, their cleanliness seen to, and the health of the herd noted. Daily inspection of all the markets. Daily inspection of the public drinking water. Dr. Cortezo particularly draws the attention of the managers of hospitals, boarding houses, and prisons to the importance of employing a company of ratcatchers. The sanitary inspector of Valencia, Senor Leoret, says that the extinction of these fecund rodents by strychnine, apart from the dangers attending its use, is not satisfactory; and he advocates obtaining a serum from the Pasteur Institute in Paris which, while actively lethal to rats, shall possess the great advantage of being non-poisonous to man.

Dr. Leoret, after a careful inspection of the ice factories of Valencia, reports them to be positively dangerous to the public health. He proposes to the Corporation (1) that the manufacturers of ice shall use well-filtered water, free from micro-organisms; (2) that they be permitted to manufacture ice from ordinary water for refrigeratory purposes and external use only; (3) that the two qualities be kept apart, and that the public be notified of the difference.

The Governor of Valencia, Senor Diaz Merry, has published in the official journal of the Province an appeal and directions to the medical officers of the cities and sub-districts impressing on them the special nature of the epidemic which threatens the province, and drawing attention to the sanitary laws of 1848 and 1855.

Dr. Ferran, who has been commissioned by the Corporation of Barcelona to study the plague in Oporto, says that, scientifically speaking, he looks on the sanitary cordon and fumigations as worthless. He looks on serum inoculation as the only prophylactic, and having been inoculated he sees no risk in investigations carried on by him. Dr. Prio reports that the plague has not spread beyond Oporto, and he looks forward hopefully to its being stamped out.

The case of a female child, three years of age, reported on the 31st of August as suffering from the bubonic plague, created a scare in Lisbon, where the case occurred.

The case was examined by Dr. Mendoza, who reported as follows:—"Having made an examination of the blood and of the secretions of the mouth, I found nothing characteristic or such as would cause me to treat it as a case of real infection. The inflammation of the glands has gone, in one place completely, and in the other it is very much lessened."

In a letter addressed to a Valencia paper, the director of the prison of San Miguel de los Reyes, Senor Millan Astray, points out the risk they ran from infection by rats. "It is clear that the criminals eat the rats, not alone in this bridewell, but in all of them, in fact they eat them and relish them in all our prisons." In the same province he states that he has seen sellers of water rats, and that they readily found buyers.

These circumstances the worthy gaol-keeper considers should make them very careful in the selection of a toxic agent for the rats, and he recommends the use of the poison agriculturists have so successfully employed in France.

The prison of San Miguel is the largest in Spain. It was built for 3,000 inmates, it contains to-day only 1,300. Under the care of Señor Millan Astray it is kept perfectly clean in every part, and the worthy Señor hopes that its good sanitary condition will enable them to keep the plague at arm's length, though the acquired taste for rat flesh of those under his care gives him some uneasiness.

Writing of the bubonic plague, and the excitement its outbreak in Oporto has caused in Spain, Don Decie Carlan thus expresses his views in *El Siglo Médico*:—

"Much discussion has taken place of late in all the important towns of Spain on the necessity of taking proper sanitary precautions to improve the present conditions in case the plague should cross the borders.

There is no Governor, nor Alcade, nor meeting of sanitary committees in which heated and extravagant speeches on the improvement of the hygienic conditions of the people, and the removal of unsanitary foci are not advocated, as well as the examination of unsanitary houses, and the punishment of those who adulterate food.

These general measures are not, however, carried out for the simple reason that there is no money, and the treasuries of the city corporations, badly administered as a rule, are empty.

It is necessary that the example shown by the Corporation of Barcelona be followed, which without any fuss, voted 125,000 pesetas for sanitary improvements and hygiene. This body holds the proper view of affairs, for in the war against epidemics, as in other wars, the principal weapon for the fight is money, money, money.

PROCRASTINATION.

Our contemporary, *El Siglo Médico*, in its last number, draws attention to the fact that the Royal Order of January, 1877, ordering the creation of a new cemetery for Madrid, and the closing of all the cemeteries within the city, remains a dead letter. This is all the more remarkable, for the order has since been repeated in August, 1884, in January, 1890, and in September, 1891.

The Operating Theatres.

CANCER HOSPITAL, BROMPTON.

FIBRO-MYOMATA OF THE UTERUS.—PANHYSTERECTOMY.—Mr. BOWREMAN JESSETT operated on a woman, æt. 45, who was suffering from fibro-myomata of the uterus. The patient had noticed for the last nine months that the abdomen was getting larger, and during the previous six months she had had more or less constant metrorrhagia. On examination of the abdomen three large bosses were discovered, one filling the left iliac fossa, the second, externally to the first, above the umbilicus, the third, smaller, on the right side. Per vaginam, the os uteri felt to be pushed down into the pelvis; by bimanual examination the tumours in the abdomen and that felt in the vagina were evidently connected. The

os was difficult to define, being drawn high up in front. At the operation the patient was put in the Trendelenburg position; an incision was made in the middle line, extending from the pubes to about two inches above the umbilicus. The mass was readily delivered through the wound, and the broad ligament on each side was ligatured close to the uterus and divided, the ovaries and tubes being left *in situ*. A flap of peritoneum was then reflected from the posterior wall of the uterus, and Douglas's pouch opened up into the vagina. A pair of long forceps having been introduced through the vagina by an assistant so as to define the posterior fornix the vagina was opened on the forceps. Another flap of peritoneum with the bladder was reflected from the anterior surface of the uterus, and the anterior fornix then opened. The uterine arteries on both sides were secured by a ligature left long, and the connecting tissues between the stump and the uterus divided and the tumour removed. All bleeding points having been secured, the peritoneum over the floor of the pelvis was carefully united by a silk suture, the stumps containing the ovarian arteries being securely covered with peritoneum, the ligatures securing the vessels which had been left long were drawn down through the vagina, which was then packed lightly with iodoform gauze. The abdomen was closed by single interrupted silkworm gut sutures taking all the tissues. Mr. Jessett said that the question of the best method of dealing with these fibro-myomata of the uterus was one of great importance; he was quite sure that the operation of the future would be either total removal of the whole uterus or supra-vaginal amputation of the cervix, the stump being treated sub-peritoneally. In cases such as the one just operated on, where the cervix was involved in the growth, undoubtedly panhysterectomy was the best form of operation. In cases, however, where the cervix was elongated preference might be given to the subperitoneal method. This form of operation, he said, no doubt could be performed more expeditiously, which, of course, in patients who were probably reduced in strength by loss of blood, was an advantage not to be lost sight of. On the other hand, it must not be forgotten that cases had been reported in which this operation had been performed and trouble had been experienced by the development of other fibroids in the portion of the cervix that had been left behind. He therefore preferred, on the whole, all other things being equal, the operation of panhysterectomy. In the operation just performed he pointed out that it might have been noticed that the ligatures securing the broad ligaments and uterine arteries were left long and drawn through the vagina. By this means excellent drainage was formed; moreover, in due course the ligatures were easily removed. In the suturing of the parietes Mr. Jessett observed that he had in several instances adopted the method of uniting, with three layers, the peritoneum by catgut, the muscles and fascia by interrupted silk sutures, and the skin by a continuous horsehair or silk suture, but he had abandoned this form of suturing the parietes in favour of the one he had just employed, as in several instances he had experienced trouble with the buried silk sutures, which caused localised abscesses, and had to be removed later on.

It is satisfactory to note that the patient made an uninterrupted and excellent recovery.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 20, 1899.

SIR MICHAEL FOSTER'S ADDRESS AT THE BRITISH ASSOCIATION.

THOSE among us who are familiar with the name of Michael Foster as the author of various textbooks on physiology, and as the diligent and ingenious investigator, will view him in a new light if they will but read the masterly address from the Presidential chair delivered before the British Association last week. The genial way in which this veteran observer handles the most recondite processes of natural science, the happiness of his phraseology, and the lucidity with which he so deftly discusses the evolution of science in its various branches, show him to be possessed of social and literary qualities which his more strictly scientific utterances had, perhaps, not led us to expect. Whether he discusses individual life as "a link in a long chain joining something which went before to something about to come," or holds forth of "the long series of living forms, living now or fitting like shadows on the screen of the past," he displays qualities of diction and thought worthy at once of the foremost exponent of physiological science and of a master of the English language. He lays a playful finger on terms such as "vital force" and "vital principle," wherewith physicists, even of the present day, are wont to disguise their inability to fathom certain biological mysteries which are still mysteries, but which we have learned frankly to admit as such pending further knowledge. We are admittedly but on the threshold of the investigation of the psychical and nervous events which "are the outcome of the clashing of nervous impulses as they sweep along the closely woven web of living threads of which the brain is made," but, he adds, we have learned by experiment and observation that the pattern of the web determines the play of the impulses, and we can already explain many of the obscure problems not

only of nervous disease, but of nervous life, by an analysis which is but a tracking out of the devious and linked paths of nervous threads. Wandering into the enticing field of embryology, we are told that the life of every living being, from the ovum to its full estate, is a series of shifting scenes which come and go, sometimes changing abruptly, sometimes melting the one into the other like dissolving views, all so ordained that often the final shape with which the creature seems to begin, or is said to begin, its life in the world, is the outcome of many shapes, clothed with which it in turn has lived many seeming lives before its seeming birth. Though he asks the ever present question whether life in its essence is worth more than before the intellectual comets of the present century shed their effulgence on the dark corners of scientific research, Sir Michael Foster is no pessimist. He worships at the shrine of science with a robust faith, both in the past and in the future, which it is good to contemplate. The growth of science, he observes, is that of a living being. As in the embryo phase follows phase, and each member of the body puts on in succession different appearances, though all the while the same member, so the scientific conception of one age seems to differ from that of a following age, though it is the same one in the process of being made, and, as the dim outlines of the future embryo become, as the being gets more distinct and sharp, like a picture on a screen brought more and more into focus, so the dim gropings and searchings of the men of science of old are, by repeated approximations, wrought into the clear and exact conclusions of later times. Not the least valuable among the many striking utterances of the master is his robust faith in science as a means of training. Gently chiding those who regard science in the light of the discoveries which, in the Victorian era, have done so much to render life longer and more comfortable all round, he points out that man does not live by bread alone, and the inexorable precision which the study of natural phenomena inculcates, is of itself, apart from its material results, a training of the greatest possible value. As a child in its infancy looks upon its mother only as the giver of good things, and does not learn until later how she was also showing her love by carefully training it in the way it should go, so they, too, have thought too much of the gifts of science, overlooking her power to guide. He insists that the training to be looked for from science is the outcome, not of the accumulation of scientific knowledge, but the practice of scientific inquiry, so that a man may have at his fingers ends all the accomplished results and all the current opinions of any one or of all the branches of science and yet remain wholly unscientific in mind. If those who are responsible for the education and mental training of the rising generation, and of generations as yet unborn, could only be brought to lay this guiding principle to mind, a great step in advance would have been taken towards shaking off the tyranny of methods ill-suited to the requirements of the present day.

SECRET COMMISSIONS TO MEDICAL PRACTITIONERS.

IT will be recollected that, some months ago, Sir Edward Fry, ex-Justice of Appeal, made himself responsible for a charge brought by the London Chamber of Commerce, that medical practitioners are in the habit of seeking or accepting secret bribes from chemists, instrument makers, and undertakers to recommend them to their patients, and that these bribes take the form of a specific percentage upon the business done through their agency. Now, Sir Edward Fry, being a lawyer of vast experience, must know that such a charge publicly made against an individual would be amply sufficient ground for an action for damages against the person who made the charge, and, being an expert in the law of evidence, Sir Edward Fry must be well aware that no hearsay gossip amongst unknown persons would be listened to for half a minute as justification for the accusation. The learned ex-Justice of Appeal is the Judge most certain to scout such a method of defence out of Court, and to charge the jury to find exemplary damages.

We must, therefore, conclude that, in thus defaming medical practitioners, Sir Edward Fry feels himself safe because the libel appears, not over his name, but as a paragraph in a report of the London Chamber of Commerce, and is directed, not against any individual, but against a profession. He must, we feel convinced, be conscious that he does not occupy a position consonant with the dignity of one of Her Majesty's judges, especially when he finds himself obliged to confess that he cannot present in the Court of public opinion a single witness to prove his case. The testimony on which he originally based the defamatory statement was that of a chemist and an optician whom, however, he declines to produce or identify, though challenged by the British Medical Association to do so, and in a letter to the *Times* last week, he not only reiterates the accusation, but tries to reinforce his proofs by the hearsay statements of an equally inno-
 minate undertaker. Sir Edward Fry writes:—"I make no charge against the medical profession as a whole. I am sure that many of its members are as incapable of taking a secret commission as Her Majesty's judges of accepting a bribe." We cannot, however, accept such an apology because, in fact, the original libel was quite general in its scope. He did not say that some doctors, or a certain class of doctors, or a limited proportion of the profession, take bribes, but he clearly implied that the practice is habitual, and is so far universal as to justify a public pronouncement by a responsible public body. To that statement, whether uttered by an ex-Justice of Appeal or by anyone else, we feel able and that it is also our duty to our profession to give the most emphatic repudiation which is consistent with politeness. We are not so stupid or so ignorant of human nature or of commercial morality as to suggest that, out of the 35,057 medical practitioners whose

names are on the *Medical Register*, there are not some—perhaps many—who will sell their professional honour for traders' tips, and in every trade or profession there always must be such a leaven. Might we ask Sir Edward Fry whether the legal profession is inviolate in this respect? Dr. Saundby, speaking for the British Medical Association, declared that "inquiries had been made which resulted in their hearing that presents had occasionally been offered for various services after the event, but that there was no case in which a commission had been offered to a person if he would do a certain thing." Sir Edward Fry demands exact particulars of the persons interrogated in Dr. Saundby's inquiries, and of all the circumstances thereof, the very information which, with reference to his own inquiries, he is unwilling or unable to give. We, and our medical contemporaries, have acquired, by decades of experience of professional practice, an acquaintance with all the phases of the medical system which Sir Edward Fry and the other amateurs of the London Chamber of Commerce cannot presume to, and we claim for our contemporaries and for ourselves sufficient independence of trade interest to allow us to speak out if we became aware of the prevalence of the bribery with which we are charged. As we believe that such abuses do not occur in any material degree we suggest that Sir Edward Fry may be permitted, without further notice, to incubate his mare's nest.

DOGMATISM IN PRACTICE.

IT is useful at times to attempt to learn from the enemy the secret of his strength. In a certain sense the quacks, meaning by that term all who practise medicine without holding any legal qualification, are the enemies of the medical profession, hardly less than they are deadly parasitic foes to the welfare of the world at large. But for all that there exists no community, however cultured, in which quackery is not at the present moment rampant. The reason for such a state of affairs is not apparent on the surface of things, and may repay a little investigation by the medical profession at whose expense quackery flourishes. Perhaps the chief element concerned is the craving on the part of the public for the definite and the specific in matters medical. The average patient goes to his doctor to know what is wrong with him, and to be told what he must do in order to get right. Now, as an elementary knowledge of medicine quickly shows, diagnosis is often hedged in with many doubts and difficulties. The quack, however, is hampered with no scruples and with no doubts; his decision is rapid and positive, and those who go to him are carried away by the sheer force of his assurance. In other words, the successful quack is endowed with strong character and is a good judge of his fellow men. From the very circumstances of the case he is for the most part brought into contact with folk of the timid and feeble kind, who want nothing but firm handling by a man of stronger will. On the other hand, let us turn

to a conscientious physician who investigates every case brought before him with conscientious care, and bestows upon it the results of a broad and experienced culture. Unless he is able to combine knowledge of men with knowledge of his profession, he is likely to add to the failures with which the medical as well as other professions abound. There is not any particular reason, however, so far as one can see, why the educated physician should admit a patient into his confidence as to the processes which have determined his conclusions concerning the nature and the treatment of the ailment before him. The wise man will state his opinion as to the nature of the malady and write his prescription. To go further is to court disaster, especially in these days of universal information, when a vast fund of ill-digested physiological information may lurk beneath the attractive exterior of the budding damsel who sits demurely in the consulting-room chair. Another great element in the success of quackery is the treatment of symptoms. The vast mass of patent medicine literature is aimed at symptoms, and indeed, for that matter, a great deal of the therapeutic teaching of the present day is based on a similar principle. Nor can there be any doubt that many a successful career in medicine has been secured and maintained by that cheap and easy road to popularity. Some day, in the greater fulness of knowledge, it will become possible to treat disease on a more rational footing. Not so long ago, narcotics, such as opium and its derivatives, occupied a foremost place in every-day medical practice. The comparative disuse, however, of drugs of that class within recent years may be regarded as one of the most significant facts of modern medicine. Instead of providing a patient suffering from intestinal disorder with a narcotic euthanasia the practitioner would now call in an operating surgeon without a moment's loss of time. As to the regulation of quackery it is an open question how far any good can be looked for from the expanding common sense of the community. Seemingly, the strong hand of the law is alone equal to the task, and it should be one of the great functions of the General Medical Council, as representing the medical profession, to indicate to the Legislature the direction in which reforms should be directed.

Notes on Current Topics.

The Medical Student and His Prospects.

A RECENT number of the *Referee* contains some pungent remarks anent the terms in which a contemporary thought fit to address the general body of medical students by way of inaugurating the Educational Number, remarks in which, in the main, we cordially concur. Why indeed insist upon the fact, if fact it be, that "the progeny of wealth and lineage is conspicuous by its absence" from the medical schools, unless indeed the intention of the writer was to impress the student with a becoming sense of his social inferiority? Perhaps on the whole it is an advance

tage that the impecunious scions of the nobility affect the Church, the Bar, and the Stock Exchange in preference to the dissecting room, but anyhow the fact is devoid of either interest or instruction. Why, again, insist upon the absolutely superfluous approval of medicine as a career expressed from time to time by "the chief political personages of the realm now living as well as their most notable colleagues who have recently passed away, thereby allying themselves with eminent occupants of the judicial bench"? The last reference, it may be assumed, does not include Sir Edward Fry, who has done what lies with him to undermine public confidence in the integrity of the profession as a whole. Surely it is quite unnecessary to trot out such reminiscences to establish the honourable nature of the calling upon which these young—may we say, gentlemen?—are about to enter. The history and traditions of medicine are surely enough in themselves to establish its claim to public consideration and respect, and it is in the highest degree undesirable to introduce the spirit of social subserviency and snobbery into an address which, if delivered at all, should have for object to impress medical students with a proper sense of the intrinsic dignity of their calling, apart from meretricious encomiums and casual expressions of condescending approval by persons in no way more honourable than members of the profession which they patronise.

Typhoid Fever in India.

It is a discouraging fact that typhoid fever in India seems to defy the efforts of the medical authorities to circumvent its ravages. From a medico-military point of view its incidence is extremely serious, inasmuch as it is responsible for a very large proportion of the sickness and mortality among the troops, thereby reducing the fighting effective to an alarming extent. It is evident that we have still much to learn in respect of the propagation of the disease, and there is every reason to believe that, in India at any rate, water is not the only, possibly not even the principal, vehicle of the contagion. It is reported that inoculation is being tried as a preventive measure, but we have little confidence in such means unless a determined effort is also made to ascertain and remove the conditions under which the disease occurs. The mischief done by typhoid fever is far greater, as far as the army is concerned, than that resulting from outbreaks of plague, and if the same attention were devoted to the question of its prevention as has been expended in fruitlessly endeavouring to check the ravages of the plague it is highly probable that some tangible results would have been obtained. It is high time Government took steps to have the whole question investigated by a body of independent experts untrammelled by military routine and specially fitted for the task.

An Epidemic of Diarrhoea.

FROM all parts of the kingdom reports are to hand of an unusually severe epidemic of autumnal diarrhoea, especially well marked in the metropolis. The

diarrhoea is of a very acute character; it is associated with febrile symptoms and severe colic, and it promptly determines an extreme degree of debility. One noteworthy feature about the epidemic is that it does not evince any special predilection for the young, a large proportion of the victims being adults, and those advanced in years. It apparently stands in no direct causal relationship to the nature of the food, and it is highly probable that the source of the mischief is water, the supply whereof having run short, with consequent increased liability to contamination. The autumnal rise in the level of the sub-soil water, especially after such a long spell of dry weather, is invariably followed by an enhanced ratio of abdominal disturbances of the fermentative type, and epidemics of this kind often usher in outbreaks of typhoid fever. It behoves us to enjoin upon the public the importance at this season of taking special precautions against the ingestion of contaminated water. It goes without saying that when the water supply is incriminated, the liability to infection through milk rises *pari passu*, and this is a point worth bearing in mind.

Political Medicine.

THE absurd suggestion that British medical men should boycott French health resorts because, forsooth, a military tribunal has rendered an unjust verdict, is hardly one that can commend itself to our readers. Medical advice is, or should be, given on medical grounds alone, and just as science knows no frontiers, so medicine knows no sentiments other than those dictated by the desire to secure the well-being of the patient. A much more serious drawback to frequentation of French health resorts is the ever-increasing dearth of English-speaking medical men who are at liberty to practise their profession thereat, owing to the absurd and ungenerous restrictions which the Government, in a narrow and ill-advised protectionist spirit, has thought fit to impose upon those who desire to minister to the medical requirements of their fellow countrymen abroad. Unless the present stringent laws undergo some modification within the near future, the inability of British invalids to procure the services of a practitioner of their own nationality cannot fail to deter many of them from leaving England in search of health.

The Cost of Vaccination.

ANTI-VACCINATION propagandists invariably lay great stress on the cost to the country of public vaccination, and they protest that there is no such thing as gratuitous vaccination. We need not discuss what is meant by gratuitous vaccination, but we may fairly ask whether £100,000 per annum, which is, roughly speaking, the annual cost of the vaccination service, is a large sum to pay for the protection thus obtained. To form an opinion we have only to contrast this figure with the cost to individual districts of a single small epidemic of small-pox. The cost of an epidemic of any magnitude would

alone devour a large portion of the sum, and a thousand cases of small-pox throughout the country would entail an expenditure of funds more than equal to the amount annually expended in vaccination, and this quite apart from the fees which medical men would reap from the paying patients. It is like whipping a dead donkey to reiterate the old but still valid argument that a good epidemic of small-pox would prove more remunerative to the medical profession than would the receipts from vaccination fees for a quarter of a century.

The Depeculiarising Process.

WITH that blind adherence to surface logic which is the characteristic of uneducated, or partially educated, people, an elder in the sect known as the Peculiar People has been visited with contumely and threats of violence by his fellow-sectaries because, in the exercise of his discretion, he determined to "try the experiment" of calling in a doctor to a sick relative. It may be that the experiment was only intended to avert the disagreeable consequences of allowing a child to die without medical treatment, but it would be more charitable to assume that the step was prompted by a sincere desire to try if the doctor could really do what the laying on of hands had failed to accomplish. Sects such as these only thrive under persecution, and no doubt this is why judges and juries display such reluctance to mete out punishment to the parents of medically neglected children. In the long run, common-sense and parental affection may be trusted to get the better of the medical ostracism which is held to be enjoined by a violently interpreted text. It is unfortunate that the victims should be for the most part children of tender years, who thus incur the rigour of tenets which they are far too young to approve or endorse. It is here, indeed, that the law steps in, because the liberty of self-privation does not extend to the defenceless young.

Case of Poisoning by Heroin.

IT is important to place on record instances of untoward effects following the use of drugs of recent introduction, and therefore, to some extent, unfamiliar to the majority of practitioners. Special interest therefore attaches to a case of poisoning following an overdose of heroin, a derivative of morphine, published in a Spanish contemporary by Dr. Espinosa de los Monteros. A man, æt. 40, suffering from asthma, was ordered 1·5 centigrammes of the drug (equivalent to about a quarter of a grain) to be given in six doses. Symptoms of poisoning developed soon after the first dose, and four hours later the patient was greatly prostrated, cyanosed and restless. There was complete amaurosis, the pulse had fallen to forty per minute and the cardiac action was very feeble. The patient complained of feeling light-headed and the lower limbs were convulsed, with some twitching of the upper limbs as well. The axillary temperature was 96·6 F., and

there was persistent nausea. On enquiry it was ascertained that the dispenser had read grammes for centigrammes, so that the quantity absorbed by the patient was a quarter of a grain. Strong coffee was administered, but the patient lay for some hours in a semi-comatose condition, and it was noted that he did not pass water. As he vomited soon after the administration of a second cup of coffee, caffein was given hypodermically at intervals of six hours. The amaurosis disappeared, and sleep quickly followed the second dose of caffein, the cyanosis cleared up and the patient gradually made a good recovery. The case gives us some insight into the physiological action of the drug and its comparative innocuousness. It is noted that the subsequent administration of the drug in the dose originally ordered was not followed by any untoward symptom.

A Clergyman as Out-Patient.

A CLERGYMAN—according to his own account—went to a London hospital to get treated for some illness or other, and has written to the *Daily Chronicle* an appalling account of the time he was kept waiting and the curt treatment he received. First of all, it would be well to ask, what right had a man of his position to be attending a hospital intended for the poor? Could he not muster the small fee required for the services of a general practitioner without trenching on the resources of an organisation founded and maintained for his needy brethren? It is people of that stamp, namely, those who can afford to pay moderate fees to qualified outside practitioners, that have to a great extent created the present hospital deadlock. The poor who go to certain of the large London hospitals are asked to contribute towards the cost of their treatment, because, forsooth, it is to be presumed the resources of those institutions have been drained by comparatively well-to-do folk. If a medical charity cannot support itself without taxing the poor in that way, then its excuse for existence appears to have died out, and the needy had better betake themselves to the Poor-law infirmaries whither, indeed, they are now driven in shoals by the overcrowding of the ordinary hospitals. The discontented clergyman appears to have entertained a delusion that he could command the best available skill at a London hospital. Perhaps he has now to some extent gauged the value of snap-shot treatment by students, harried and hurried house residents, and overworked consultants. When will the hospitals purge their walls of these unworthy applicants for relief?

Advantages of Provincial Medical Schools.

THERE can be no doubt whatever that the smaller provincial schools afford to the medical student in a conspicuous degree the advantage of acquiring a knowledge of practical work that can never be derived from books and lectures. In London the overcrowded state of the teaching hospitals forbids the individual handling of that abundance of clinical material which is essential to the turning out of sound practical

men. Where a student in the metropolis would have a meagre allowance of one or two beds in the country he might have a ward full, to say nothing of the chance of performing many or most of the minor operations. Of course, it must be admitted that he would have more teachers in a London school, but even that is not always an advantage. Among the smaller provincial schools, Bristol, one of the oldest, has always been distinguished for the quality of its teaching. Of late years the status of the school has been materially advanced by its affiliation with the University, and the erection of handsome new buildings. Quite recently another great step has been taken to increase the facilities of students in obtaining clinical material. The Royal Infirmary, dating from ancient times, has lately joined forces with the more modern Bristol Hospital, so far as the training of students is concerned. A large surgical practice is always to be witnessed at both institutions, owing to the position of the town as a large manufacturing centre and seaport. For a student who does not contemplate consulting or special practice the advisability of spending a portion of the whole of his course of study in one of the smaller provincial schools is worthy of consideration.

Vegetarianism.

THE Annual Congress of the cult of the vegetarian was in full swing last week in London. It is to be noted about these meetings that there are always plenty of curious opinions and statements advanced by members, and this year showed no falling off in that particular. A Miss Eccles advanced the idea that there was nothing in vegetarianism inconsistent with beauty, whilst in the eating of flesh there was nothing whatever consistent with it. We may hazard the opinion that an analysis of the lives of famous beauties, living and dead, would show few, if any, vegetarians among them. One speaker maintained there was a close affinity between art and vegetarianism, and expressed the belief that the anti-flesh faith he held was beginning to lay hold of the artists and poets of the present day. Well, it may be so, but the fact is not conspicuous among the Bohemian circles in the metropolis, where art sits as goddess. Another gentleman, a Dr. Black, suddenly made a savage onslaught on the bull fights at Boulogne. He said it was the duty of the Congress to show they had not the slightest sympathy with such terrible actions. Does he imply that those who eat beef must necessarily be brutalised sufficiently to patronise a bull fight? An opponent of the movement had the hardihood to declare that flesh-eating was like smoking—some took it up because they liked it, and *vice-versa*. One lady eschewed cheese because it was made from milk and curdled by rennet, which had to be obtained from the calf's stomach. *De gustibus non est disputandum*.

The Treatment of Urinary Incontinence in Girls.

URINARY incontinence in girls is a fairly common and always a very troublesome affection. In a minority of these cases treatment having for object to correct abnormal conditions of the urine, or to destroy intestinal parasites, is attended by a certain measure of success, but in many, possibly in the majority, it is the result of a neurosis, and in such cases treatment by drugs usually fails to afford relief. We are now in possession of a tolerably large number of cases of incontinence in which recovery has followed gradual distension of the bladder by an innocuous fluid, boracic acid solution, for example. In a recent number of the *Boston Medical and Surgical Journal* Dr. Haven records two further cases successfully treated by this method in girls, both 18 years of age. He employed a 4 per cent. solution of boracic acid. In one case the bladder admitted eight ounces under pressure, and in the other only three and a half ounces. His plan was to inject until discomfort was produced, then directing the patient to retain the fluid as long as possible, usually from ten to fifteen minutes to begin with, though this period could soon be extended. Distension was practised every other day and improvement soon followed. The treatment was continued until the bladder would admit twenty ounces, and then all symptoms having subsided it was discontinued. The total duration of the treatment was three and five months respectively, but in some of the previously recorded cases much less time was required to effect a cure.

Volunteers Medical to Fight the Plague.

IN view of the imperious necessity of providing further medical aid in the treatment of patients suffering from plague in India, the Government has selected twenty medical men and thirty nurses as volunteers, most of whom will leave this country for Bombay in the course of the next few days. We publish elsewhere a list of the volunteers whom we wish God speed in their noble mission. The spectacle of a number of young medical men leaving on such a perilous mission is at least worthy of enthusiasm as that of a regiment of cavalry leaving England on a destructive mission under circumstances which, as far as risk to life is concerned, compare favourably with those of the non-combatants.

Medical Certificates and Hospitals.

A QUESTION of considerable importance to hospital medical officers has cropped up at the Cardiff Infirmary. It seems that though certificates to clubs and friendly societies are given without payment, the same indulgence has not been extended to certificates intended to serve as the basis of claims for compensation. In reality there are two questions at issue—first, whether such certificates are to be charged for; and secondly, to whom such fees, if paid, should belong. Looking at the question on its merits, it is evident that both custom and humanity justify the practice of giving certificates testifying to inability

to work for the purpose of obtaining club money. It is, on the other hand, obviously unfair to expect medical officers virtually to act as witnesses in actions brought to recover compensation without fee or reward, for that is what it comes to, and we strongly endorse the action of the medical staff in refusing to be coerced into doing so. With regard to the question of the right to fees paid for such certificates the infirmary can have no claim thereto. If the medical officer, having refused the certificate, were called as witness he would certainly expect to pocket whatever fees were forthcoming and the giving of certificates stands on exactly the same footing. The matter is being enquired into by a committee appointed for that purpose, and we trust that they will arrive at this common-sense conclusion.

The Opening of the London School of Tropical Medicine.

WE are informed that there is to be no formal ceremony at the opening of the London School of Tropical Medicine which is to take place on the 1st prox. The fact is the hospital buildings which adjoin the school have not yet been completed, and it is deemed preferable to defer the real opening ceremony until a later date. It is hoped that an endowment fund will be subscribed, and should the response be generous enough a museum and library will also be established in connection with the school.

Herbalist versus Surgeon.

AN odd instance of refusal to pay for medical attendance was heard last week before the County Court judge at Stonehouse, when Mr. Elgar Down sued an ex-patient for his fees in connection with the treatment of an injured knee. The defendant based his refusal to pay on the ground of wrong treatment, but the only evidence he was able to allege in support of his contention was the assertion of an old woman who practises as bonesetter and herbalist. The defendant had been advised to go into the hospital, but had refused to accede to the suggestion because, he said, his brother had been improperly treated there, an assertion which elicited from the judge the remark that he must belong to an unfortunate family. Ultimately, of course, a verdict in favour of the defendant was given. We may congratulate the plaintiff *en passant* on having been wary enough in such a case to call a fellow-practitioner in consultation, a course worthy of imitation, considering what damage to a surgeon's reputation an unfavourable issue must needs have.

A Taboo on Raw Cockles.

TYPHOID fever has been somewhat rife of late at Exeter, and suspicion has been cast upon raw cockles, a dietetic luxury of which school children in that part of the country are notoriously enamoured. A resolution has just been passed by the Exmouth District Council forbidding the sale of this bivalve in a raw condition, a decision which appears to have caused considerable local excitement. In view of

the fact that the river Exe receives the sewage from various towns and villages in its wake, it is evident that the shell-fish grown in its estuary are very likely to be contaminated, but it is rather a pity that the order only deals with the local sales. Customers at a distance are also entitled to protection, and what is not good enough for Exmouth ought to be discarded from markets further afield.

Stamp-licker's Tongue.

SOME months ago a paragraph was published in these columns upon the subject of "stamp-licker's tongue," a phrase that was created and evolved in our own office and thence issued to the world at large. The article in question enjoyed a wide popularity, and was quoted by a great many newspapers, both at home and abroad. The phrase has evidently taken a place in the English language, for last week we saw it in a prominent position in one of the London daily newspapers, to wit, the *Daily Chronicle*. It has been dignified, we find, with a further extension to label-licker's tongues, and no doubt, as time goes on, the list of specific articles giving rise to lickers' tongues will be considerably enlarged by journalists in search of novelty. As to labels, it is interesting to note, from the final report of the departmental committee of inquiry upon certain dangerous trades, the following passage:—"With regard to the practice of licking labels for use in threadmills and other factories, they state that in many cases artificial dampers are being introduced with obvious advantages. Therefore, without recommending that the licking practice be prohibited, the committee express the hope that manufacturers generally will abandon a method which is certainly unnecessary, and which carries with it possibilities of injury." It is even stated that some women lick several thousand labels daily. Without wishing to cause needless alarm, we may say that such a proceeding would be calculated, in our opinion, sooner or later to set up cancer of the tongue. In that way, moreover, the poison of syphilis and of other communicable diseases might be readily distributed upon the article labelled in so primitive a manner.

The Toxic Effects of Formaldehyde.

FORMALDEHYDE preparations used for antiseptic and germicidal purposes are quite strong enough to cause harmful, if not fatal, effects upon those who may inadvertently, or otherwise, imbibe them. A case of fatal poisoning, for example, is recorded as having occurred in a school in Indiana, where a youth, æt. 26, drank about 2 ozs. of a 4 per cent. formaldehyde solution used for treating seed potatoes. Death occurred about twenty-nine hours afterwards from asthenia. Some escharotic changes were visible at the post-mortem examination in the stomach, and the mucous membrane at the upper and middle thirds of the œsophagus was slightly inflamed. The immediate effect of swallowing the poison was to cause vomiting, the vomited matter containing traces of blood. In the treatment emesis was encouraged with a sub-

cutaneous injection of apomorphine, and large quantities of albuminous water were administered by the mouth without causing any discomfort while being swallowed. For a time the man seemed to make a good recovery, but at the sixteenth hour his pulse began to fail. Despite the subcutaneous injections of strychnine and of seventeen ounces of normal saline solution, together with doses of nitro-glycerine and sparteine by the mouth, death from heart failure, as mentioned above, took place. This is, we believe, the first recorded case in which a fatal result has ensued from swallowing a formaldehyde solution, and it is therefore of some toxicological interest.

Curious Deadlock in a London Parish.

It will be remembered that during the past summer a considerable stir was created in the South London Parish of St. Olave's over the removal of bodies from the Church of St Thomas. The Medical Officer of Health, Dr. Bond, was suspended by the Vestry, but that step has not received the sanction of the Government, who have directed the rescinding of the suspension order. The St. Olave's Board, however, have appointed Dr. Dixon Medical Officer of Health for Bermondsey, as temporary Medical Officer in place of Dr. Bond. This state of affairs presents a curious insight into the machinery of local health administration in the metropolis. St. Olave's includes a small but very wealthy area, and its good sanitation is a matter of no little importance not only to its enormous day population, but also to the many poor workers who dwell in that quarter. The sanitary administration, for all its size and complexity, is entrusted to the care of a Medical Officer of Health, who also has charge of the health interests of Holborn. The St. Olave's Board, having suspended Dr. Bond turn to Dr. Dixon, who already divides his energies between the cases of private practice and the sanitary charge of Bermondsey, with a population of some 80,000 souls. So busy is Dr. Dixon, that important health prosecutions in Bermondsey are generally conducted by one of his subordinate inspectors. Of a truth it is time Mr. Balfour reformed the terms of these important posts.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

LARGE CHARITABLE BEQUESTS.—By his will, the late Mr. Walter W. Pollock, of Rhindmuir, has left the following legacies, viz., Glasgow Royal Infirmary, £10,000; Victoria Infirmary, Glasgow, £10,000; Royal Glasgow Asylum for the Blind, £5,000; Western Infirmary, Glasgow, £5,000; and the Royal Infirmary, Edinburgh, also coming in for £10,000 by Mr. Pollock's will.

DEPLOABLE SANITARY CONDITION OF KILSYTH.—There has been a great increase in the number of cases of enteric fever and of scarlet fever during the last few weeks in this burgh, several deaths having resulted therefrom. The fevers have been spreading since the end of July, the cause of the outbreak being attributed to defective and untrapped drains. It was pointed out at a recent meeting of the Police Commissioners that the origin of the outbreak

was similar to that of the recent Paisley outbreak, there being no less than twenty-three direct connections from the sewers into the water-mains, and it was also mentioned that during the summer the ash-pits were allowed to overflow, while the towns'-men were engaged on work which should have been contracted for; liquid filth from ash-pits percolated through walls into washhouses and lay in pools around houses, giving off most offensive stench, which pervaded the houses. The meeting finally agreed that the Sanitary and Drainage Committee should meet and consider what steps should be taken to remedy this deplorable condition of matters, which is a glaring disgrace to the town.

GLASGOW CORPORATION BACTERIOLOGIST.—The sub-committee having sent to the Health Committee the two following names for the appointment of bacteriologist, which carries with it a salary of £350 per annum, viz., Dr. Robert MacNeil Buchanan, at present teacher of Medical Jurisprudence in Anderson's College and Mr. David McCrorie, L.R.C.P. Edinburgh, at present lecturer on Bacteriology in St. Mungo's College and Bacteriologist to the Glasgow Royal Infirmary, the voting for the appointment took place at the Town Council meeting on Monday last.

Correspondence

ANTISEPTIC v. ASEPTIC.—A PROTEST.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In one of the Notes in the current number of your journal, under the heading, "Successful Removal of Sarcoma of Brain," occurs the following:—"The brain has been brought within range of practical surgical therapeutics *simply and solely by the introduction of Lister's system of aseptic surgery.*" It is against the words in italic that I indignantly protest. Lister has no claim whatever, and must feel surprised that a claim is now made on his behalf, to the credit of having introduced aseptic surgery. It is to the late Mr. Lawson Tait and myself that this credit belongs; for it was we who initiated and promulgated, in the face of envenomed opposition, what is now called aseptic surgery. We were satisfied with the use of the simple English term "cleanliness." But aseptic is a word to conjure with. It is due to the memory of the late Mr. Lawson Tait that this claim, which requires no substantiation at my hands, should be thus publicly made. As for myself, I have ceased to expect that the part I have played in this matter would be publicly acknowledged, though I have never met with anyone in recent years who would venture to my face to contest or fail to admit it.

There appears to me to be much confusion of ideas prevalent with regard to the meaning of the terms "antiseptic" and "aseptic," for, while it is quite correct to speak of having just done an antiseptic operation, it is utter nonsense to say that one has just done an aseptic operation. I have little hope that men will cease to expose their negation of such an elementary principle as the use of words in their proper sense, so long as the existing prejudice and unreasoning faith remains.

I am, Sir, yours truly,
GEO. GRANVILLE BANTOCK.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. NURSES OF THE LATEST FASHION.

SIR,—I should like to add my quota of indignation to that of Dr. Walsh at the publication of the articles in your paper reflecting so unjustly upon the modern nurse.

To attempt to convict a whole class of professional women of education, high training and extreme value, because one or two of their number fail to attain to the high standard of their calling and fall by the wayside is unjust and unfair.

What would Mr. Gant say if some elderly matron were to write an article in a nursing journal detailing the

crimes of a "Dr. Collins" and head it "Modern Surgeons?"

The art and science of nursing has fortunately gone on progressing side by side with modern surgery; the modern patient has advantages at the present day when operated upon, which not even the skill of a Gant and the wealth of a Rhodes could have secured for him in the past.

Had not the modern nurse been more highly educated than her sister in the past, modern surgery would have been very heavily handicapped.

I am sure Mr. Gant will find very few, if any, of his colleagues who will support his views of the nurse as she is at the present time. The more highly trained she is, the less likely is she to fall into the errors as depicted by the imaginative writer.

It is strange how few people can write sensibly of the hospital nurse; they either describe her as an angelic being in a costly uniform whose sole duty apparently is to "lightly press the fevered brow of a patient with a cool hand," or as the extraordinary character whose sole existence lies in the imagination of a Gant or a Hall Caine.

The truth is, the modern nurse is as impossible to describe as the modern physician or surgeon. If she were mechanical or "typical" it would only show that she was unfit for her work. To be a good nurse she must be "personal," and bring to bear upon her duties individuality and tact. The only remark I can add is to hope that, if Mr. Gant ever becomes ill, he will find it more easy to meet with an honest nurse than he appears to imagine. I am quite sure that no accredited association could supply one *a la* Gant.

I am, Sir, yours truly,
ALF. BATEMAN.

49 Devonshire Street, W.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—I for one fail altogether to see the purport of Dr. Walsh's criticisms on Mr. Gant's interesting contributions on the above topic, nor is there anything I think that can be regarded as "a prurient and indefensible attack upon a sisterhood which deserves tender treatment from all mankind."

It is impossible to conceal the fact, which Mr. Gant has not overdrawn, that the tendency of the majority of trained nurses of the present day, and this no doubt due to the innate vanity of the female mind, is to supersede the ordinary medical attendant, and to take advantage of public credulity, and the practitioner of the rising generation must have the courage and firmness to put down any airs on the part of a nurse who attempts to play first fiddle by giving her as wide a berth as possible. I happen myself to have been brought into contact with more than one of these individuals, and there resides in the locality where I practise what is known as a parish nurse, appointed by an irresponsible Church community, a person of some refinement, and a good deal of mannerism, but as she altogether exceeds the duties of a nurse and carries on unqualified practice, I have felt it my duty, in accordance with the edict of the Medical Council which prohibits unqualified practice, to refuse in any way to recognise her.

I am, Sir, yours truly,
A GENERAL PRACTITIONER.
London, September 16th, 1899.

CHRONIC PHARYNGITIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In his letter in your last week's issue Mr. Lennox Browne dissents from two statements selected from my paper on "Chronic Pharyngitis."

He first suggests that the importance of nasal obstruction as an etiological factor in chronic pharyngitis was recognised long before a considerable number of these cases could have passed through my hands. In proof of this he quotes from the first edition of his work in 1878, "ten years before I took my degree," that "Nasal respiration is often obstructed in cer-

tain pharyngeal diseases." This is an abstract statement showing that the association of nasal obstruction with "certain pharyngeal diseases" had begun to be remarked on, but there is not a word of suggestion that any causal relation existed between the obstruction and the diseases. Mr. Browne has to come down so late as the 1890 edition of his work before he can show he was alive to the fact that the condition of the nose exerted any influence on the health of the throat. I can go further, and say that even in the 1893 edition nasal obstruction, the prime cause, as I hold, of chronic pharyngitis, is relegated to the tail of a long list of causes, a number of which are at the present date regarded as survivals of a laryngological middle age.

Again, when I said the necessity for rhinoscopy in throat disease was only pointed out a few years ago, I was not under the impression that the art of rhinoscopy was only then discovered.

I could hardly have gone through the Dublin School without knowing that the post-rhinal mirror was used by Sir William Wilde even before Czernak published his paper in 1859. But from this we have to skip an interval of time measured by quarter centuries before we come to the period when the regular examination of the nose in every case of throat disease was inculcated by the teachers in the subject.

And this, I think, justifies the statement, that though the art has long been known, the necessity for its practice in diseases of the throat is a matter of quite recent knowledge.

In conclusion, I have to thank Mr. Browne for his generous criticism of my paper.

I am, Sir, yours truly,

ROBERT H. WOODS.

39 Merrion Square, Dublin,
September 15th, 1899.

HOSPITAL CARDS AS ADVERTISEMENTS IN SHOP WINDOWS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—When will the leaders in medicine and surgery cease to have their names and qualifications placarded in this vulgar way? I see the hospital cards in various colours gradually creeping into the windows of pharmaceutical chemists, druggists, instrument makers, &c. What object can there be in so fulsome a display except letting the public know the names of physicians, surgeons, specialists, and consultants? Surely our clinical hospitals have not made their reputations by hospital cards. I don't believe any student is attracted to a hospital through such media. Hospitals are known by the work done inside their walls—sound teaching, punctuality of the staff, honest work done in the long run makes the name of a hospital, and attracts patients and students alike. If students before deciding on a hospital would go round the wards, say in October, and observe and listen, the hospitals with "drones" would find it easy to accommodate the class, and the genuine teaching hospital would be filled with young men anxious to learn their profession; otherwise it is obvious that the purpose and true interests of any clinical hospital cannot be subserved by the exhibition in a druggist's window of a partly coloured advertisement.

I am, Sir, yours truly,

DUBLIN CLINICAL TEACHER AND OPERATOR.

September 16th, 1899.

SCARLATINA CASES IN BUILDINGS IN CLOSE PROXIMITY TO GENERAL CLINICAL HOSPITALS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I think it is high time for the authorities to take the necessary steps to put a stop to the highly dangerous practice of having hot-beds of so deadly a disease as scarlatina admitted into wards in close proximity to the General Hospitals within the City. Smallpox and cholera are not admitted to such wards—why scarlatina? From start to finish scarlatina is most

dangerous, and, from the commencement of the desquamation stage, six weeks must elapse before such cases can be removed home or to a convalescent home. Independently therefore of the risk to the patients, nurses, and staff, the expense of such cases is very great. The beds occupied with patients convalescing from scarlatina for such a long period as six weeks is not only a great tax on the hospital funds but a great injustice to other cases, who are thus debarred from obtaining admission into the hospital wards.

I am, Sir, yours truly,
PROGRESS.

September, 1899.

New Surgical Appliances.

NEW UTERINE PREHENSILE AND COMPRESSION FORCEPS.

DR. ALEXANDER DUKE, of Cheltenham, has sent us the following description of a new instrument designed by him:—

The instrument here depicted will be found useful both as a hæmostatic forceps in cases of passive hæmorrhage from the unimpregnated uterus, metrorrhagia, &c., and also in cases of free hæmorrhage in impending abortion in the early months of pregnancy.

A duckbill or cylindrical speculum is first to be introduced and the parts cleansed by hot water (syringing or otherwise), my self-retaining tenaculum hooked into lip of "os" will draw cervix within grasp of forceps, the latter are now to be closed sufficiently to arrest the flow of blood, locked and left *in situ* so long as required, while patient lies quiet on bed or couch. To the busy practitioner on his rounds, the value of this instrument (by the saving of time alone) will be apparent, more especially in cases of impending abortion in the early months, when by retaining the blood in utero it will distend the cavity, separate the membranes, and hasten the evacuation of the uterus when forceps are withdrawn. It will also prevent the necessity for plugging the vagina, thus avoiding the discomfort to the patient by pressure on bladder, &c., and the unpleasant removal of an offensive tampon.

These forceps will in addition be found valuable during the operations of supra-vaginal amputation of cervix uteri and vaginal hysterectomy in cancerous cases, more especially when tenaculum or volsella fail to hold.

The convex shape of blades will also prove a guide to the preliminary incisions in vaginal roof when cervix or entire uterus is being removed from below, and by opening the blades to their full extent and pressing same upwards will stretch the vaginal fornices and facilitate the removal of cervix in the operation of abdominal hysterectomy, the instrument being held by assistant (like Mr. Bowreman Jessett's speculum), the rack at lock keeping blades in position.

The instrument has been most carefully made by Messrs. Arnold and Sons, West Smithfield, from my sketch and description. The rubber cord let into concave sides of jaws prevent injury to cervix from continued pressure. The blades are detachable and easily sterilised by placing in boiling water. I have found forceps most useful, and trust they may prove equally useful to others.

PERSONAL.

SIR WILLIAM TURNER, F.R.S., of Edinburgh, has been elected president of the British Association at the next annual meeting, which will take place at Bradford.

Literature.

ELEMENTARY PHYSIOLOGY. (a)

THIS excellent little manual has, professedly, been prepared for the benefit of "those who have no previous knowledge of the subject;" and with the earnestly expressed hope "that it may remove some of that deplorable ignorance which is so often met with, even among fairly well educated people, as to the general structure of their own bodies, and the actions which take place within them during life."

We congratulate the author on the result of his labour. He has made an excellent selection from the vast mass of his material, and has arranged it judiciously, and with the least possible amount of technical nomenclature. Following a general introduction, we have three chapters devoted to a description of the structure of the body: the skeleton and its articulations, the muscular system, and the viscera. Then the author proceeds to deal with the functions: circulation, blood, diet, digestion, absorption, and metabolism, respiration, animal heat, excretion, the nervous system, and the senses.

The text is illustrated by a series of 125 drawings, there is an appendix of well-selected practical exercises, and a series of questions by which the reader can test his progress and strengthen his memory as he proceeds with his reading. There is also, we are glad to see, a good index.

Accordingly, we consider that this volume has made a thoroughly honest "bid" for public patronage. We congratulate the author on the skill and judgment which he has brought to bear upon his task, and on the completion of the work as it lies before us. We also feel certain that it will meet at the hand of the general reader the cordial reception which it most assuredly deserves.

"TWENTIETH CENTURY PRACTICE." (b)

THIS important volume contains nine articles:—Influenza, by Professor Dittmar Finkler, M.D., Bonn; Typhus Fever, by Eduardo Licéaga, M.D., Mexico; Plague, the joint production of S. Kitasato, M.D., Tokio, Japan, and A. Nakawaga, B.Sc., M.D., Tokio, Japan; Glanders, by Frank S. Billings, M.D., Grafton, Mass.; Anthrax, by the same writer; Foot and Mouth Disease, by Ismar Boas, M.D., Berlin; Actinomycosis, by Emil Ponfick, M.D., Breslau; Rabies, by Nathaniel Garland Keirle, M.D., Baltimore; and Pyæmia and Septicæmia, by J. McFadden Gaston, M.D., Alanta, and J. McFadden Gaston, jr., M.D., Alanta.

The now vast subject of influenza is very ably treated by Professor Finkler. The frequency and mortality of the so widely diffused epidemics of this disease that have occurred of recent years have brought it so prominently before all members of the profession in all civilised communities, that the subject has been brought broadside in collision with the proud-crested wave of latter-day scientific research, and has in consequence been so thoroughly investigated in all its relationships, that, as Dr. Finkler truly observes, "influenza has given us occasion to test all the modern attainments of medical science." We thoroughly admire and proudly sympathise with the feelings which dictated the following:—"It may be truly said that influenza has become the teacher in many branches, and it has demonstrated to the world such thoroughness of methods on the part of physicians and investigators, that our profession has a right to feel proud of its members." This truly magnificent article occupies 249 pages of the volume before us; and it is hardly necessary to add that it omits nothing worthy of record that history or scientific research has hitherto taught the most reliable investigators on the

subject. It is a thesis which we must emphatically say does the highest honour to the scientific attainments, clinical discrimination, patient and thorough research and philosophical judgment in the selection and arrangement of material herein displayed by the author.

The second article in position—and in dimensions—is that on typhus fever. It may look a little strange to many of us British Islanders who see so much of this fever at home to have the future standard of the subject imported from Mexico. The article is, however, a very good one. The writer has, of course, to lament the non-discovery of the pathogenic microbe, and also of a specific remedy for the cure of typhus.

In the article on plague, Dr. Kitasato gives full instructions for the differential diagnosis between the *bacillus pestis* of Yersin and that which he has himself described. "Further bacteriological investigations of the plague are desirable, since it is necessary that the scientific world should come to some definite conclusion as to the etiological bacilli, before ortho-therapy and preventive inoculation can be instituted on a truly rational basis."

"Glanders" is ushered in by a definition which we felt irresistibly impelled to read a second time. It is worded as follows:—"Glanders is an endogenous, obligatory-parasitic, invasio-infectious disease, due to the pathogenic action of a specific bacillus within the body of a suitable host, which finds its historico-primary origin and its present genesis invariably among the solipeds, principally the horse, from which it is extended to other animals and to man, directly or indirectly, but not to cattle and swine." This definition did not lead us to expect too high a standard of scientific and clinical taste and discrimination; which, possibly, partly accounts for the fact that we were not disappointed.

The article on rabies is one which we perused with pleasure as well as instruction; it is extremely well written, and displays judgment and power of personal observation of a very high order.

The volume closes as it began, with an able and carefully-prepared article (Pyæmia and Septicæmia). In the introduction the authors express dissatisfaction with the position of the boundary line between medicine and surgery. "The line of distinction between surgery and medicine has been generally recognised as external and internal, but this does not give so good an idea of the difference as a division into organic and functional disorders. A mere temporary engorgement of structures which is not accompanied or followed by radical changes in the organisation of the tissues, and which is amenable to the action of drugs comes properly under the care of the physician. But a modification of structure as to size, shape, or density, whether internal or external, belongs to the domain of the surgeon." Whether or no the profession on our side of the Atlantic may think this definition eligible for all future use, we venture to say that there will be no second opinion as to the value of the article towards which it leads. We consider that it is one of the most carefully thought-out and sensibly-written of the many which have hitherto appeared in this magnificent encyclopædia.

AN EXPERIMENTAL RESEARCH INTO SURGICAL SHOCK. (a)

THIS beautifully-printed and well-illustrated volume places before its readers the results of a series of (approximately) blood-curdling experiments on many quadruped members of the animal creation, with the view of throwing some light on the nature of surgical shock when met with in the lordly biped, man. The experiments have certainly been carried out with great care; they were also originally selected with excellent judgment, as tending in their results

(a) "Elementary Physiology." By Benjamin Moore, M.A., late Sharpey Research Scholar, and Assistant Professor of Physiology at University College, London. With 125 illustrations. Longmans, Green, and Co., London, New York, and Bombay. 1899.

(b) An International Encyclopedia of Modern Medical Science. By leading authorities of Europe and America. Edited by Thomas S. Stedman, M.D., New York City. In 20 volumes. Volume XV., Infectious Diseases. London: Sampson, Low, Marston, and Company, Limited. 1898.

(a) "An Experimental Research into Surgical Shock." An essay awarded the Cartwright Prize for 1897. By George W. Crile, A.M., M.D., Ph.D., Professor of the Principles of Surgery and Applied Anatomy in the Cleveland College of Physicians and Surgeons; formerly Professor of Physiology in the Medical Department of the University of Wooster; Attending Surgeon to the St. Alexis and Cleveland General Hospitals, Philadelphia. London: J. B. Lippincott Company.

to throw the strongest lights on the dark places of the hitherto very obscure condition of surgical shock.

A great many of the conditions here artificially produced on members of the quadruped families will, we trust, be seldom met with in our practice on the persons of our biped *confrères*; but we consider the volume a very important one, and one which should be carefully read throughout by every practising surgeon. It is a most carefully-prepared contribution to the increase of our knowledge of one of the most mysterious conditions with which we have had to deal.

PASS LISTS.

University of Dublin.

At the first Examination for the Degree of Bachelor in Medicine, held this month, the following candidates satisfied the Examiners:—

Old Regulations.—1. Chemistry with Chemical Physics.—Ernest George Annis, M.R.C.S., L.R.C.P., D.P.H., Alfred James Bulger, M.R.C.S., L.R.C.P., Philip Gell Garrett, M.R.C.S., L.R.C.P., Ernest James Miller.

New Regulations.—1. Elementary Anatomy and Biology. Chemistry and Physics. Honours—First Class.—Arthur Gibson Dunn.

Honours—Second Class.—William Henry Peacock.

Pass List.—John Frederick Bridge, John Wilfrid Caton, Edgar Fletcher Edmunds, Evelyn John Evatt, Daniel Richard Gunn, Francis Jollie Gowans, George Brittan Gill, William George Thomas Hepplewhite, William Hughes, John Thomas McKay, Joseph Collingwood Stewart.

Chemistry and Physics. Frederick George Armstrong, Walter Donald Carruthers, Wilfred Ralph Levester Drawbridge, Margaret Douglas French, Arthur Henry Fullerton, Bryden Glendinning, William Edward Hopkins, Charles Robert Lease, George Edward Victor Morris, Flora Murray, Christie Muthuswamy-Anthonv, Harry Carlisle Sturdy, M.R.C.S., L.R.C.P., Gayton Warwick Smith, Herbert Hoyle Whaithe, Auburn Lawrence Wilkinson, John Robert Wylie.

Elementary Anatomy and Biology.—Ambrose Harold Bateman, Harold Linton Currie, William Watkiss Jones, Sidney Nix, Leslie Martin Roeten, John Malcolm Shaw.

Medical News.

Vital Statistics.

THE deaths registered last week in the thirty-three great towns of the United Kingdom corresponded to an annual rate of 25.2 per 1,000 of their aggregate population, which is estimated at 11,404,408 persons in the middle of this year. The deaths registered in each of the last four weeks in the several towns, alphabetically arranged, correspond to the following annual rates per 1,000:—

Birkenhead 18, Birmingham 28, Blackburn 24, Bolton 33, Bradford 23, Brighton 31, Bristol 20, Burnley 43, Cardiff 25, Croydon 18, Derby 26, Dublin —, Edinburgh —, Glasgow —, Gateshead 21, Halifax 19, Huddersfield 22, Hull 27, Leeds 18, Leicester 25, Liverpool 32, London 22, Manchester 32, Newcastle-on-Tyne 35, Norwich 23, Nottingham 27, Oldham 25, Plymouth 22, Portsmouth 21, Preston 28, Salford 31, Sheffield 30, Sunderland 31, Swansea 22, West Ham 22, Wolverhampton 36. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From measles, 3.2 in Burnley; from whooping cough, 1.4 in Cardiff; from fever, 1.8 in Sunderland; and from diarrhoea, 6.3 in Nottingham, 6.4 in Sheffield, 7.5 Bradford, 7.9 in Sunderland, 8.4 in Liverpool, 8.8 in Birmingham, 10.2 in Brighton, in Leicester, and in Hull, 11.5 in Manchester, 13.3 in Preston, and 13.8 in Bolton. The 70 deaths from diphtheria included 24 in London, 6 in Birmingham, 6 in Liverpool, 5 in Leicester, 4 in Leeds, and 4 in Sheffield. One death from small-pox was registered in Hull, but not one in any other part of the United Kingdom.

The Mortality of Foreign Cities

THE following are the latest official returns, and represent the last weekly death-rate per 1,000 of the several populations:—Calcutta —, Bombay 36, Madras 34, Paris 16, Brussels 17, Amsterdam 14, Rotterdam 21, the Hague 18, Copenhagen 22, Stockholm 17, Christiania 20, St. Petersburg 21, Moscow 29, Berlin 25, Hamburg 22, Dresden 25, Breslau 27, Munich 23, Vienna 17, Prague

23, Buda-Pesth 18, Trieste 19, Rome 14, Turin (ten days) 18, Venice 21, New York (including Brooklyn) 19, Philadelphia 15.

Typhoid outbreak in Kent.

A SERIOUS outbreak of typhoid fever in a range of cottages by the side of the river Stour, at Asford, Kent, is causing great anxiety to the authorities. Twelve out of thirty-three persons living in the cottages have been attacked. Owing to the great heat, the infant mortality for the past month is the highest on record.

Suicide of a Medical Man.

THE suicide by prussic acid of Mr. Marwood Sanderson, F.F.P.S. of Loftus (Yorkshire), which is reported to have occurred on the 11th inst., naturally caused much local excitement. The deceased was 60 years of age, and was possessed of considerable means. No reason has been discovered to explain the regrettable occurrence.

Yellow Fever in North America.

CLOSE upon two hundred cases of yellow fever are reported to have occurred at Key West, and three suspicious cases landed at New York, from a vessel hailing from Key West, have been diagnosed as yellow fever. With the approach of colder weather, it is hoped that no further spread of the disease will take place.

The Sunderland L.G.B. Inquiry.

AN inquiry, ordered by the Local Government Board, into the conduct of Dr. Burns, a Poor-law Medical Officer, has just come to an end after a nine days session. The question under consideration was whether or not the medical officer in question had been guilty of inebriety in the discharge of his duties, and the decision of the Board will be made known very shortly. Dr. Burns was defended by Lord Coleridge, who made a powerful speech on his behalf after the evidence had been taken.

The Bubonic Plague in India.

THE following gentlemen have been selected as volunteers to proceed to India for the purpose of ministering to the requirements of plague-stricken patients:—Harry Cowper Patrick, M.D., C.M., Glasgow, who was on plague duty in Bombay between 1898 and 1899, and was invalided home for enteric fever; Charles Thomas Costello, M.B., B.Sc., Dublin, who served on plague duty in Madras last year; William Morrison, M.D., Edinburgh, B.Sc., Biological and Public Health, Edinburgh, who has served as Medical Officer in China; James William Otto van Millingen, M.D., C.M., Glasgow, who served for two months on plague duty Alexandria; Reginald A. Farrar, M.D., B.Ch., M.A. Oxon, M.R.C.S., England, L.R.C.P., D.P.H., Cambridge; Alexander Samuel Faulkner, F.R.C.S., Edinburgh, M.R.C.S., England, M.R.C.P., L.M., Ireland, a retired surgeon-major of the Indian Medical Service; Edward Lewis Hunt, M.R.C.S., L.R.C.P., who served on plague duty Bombay 1897-98; Henry William Beach, M.R.C.S., England, L.R.C.P., London, D.P.H., Cambridge, who served two years plague duty in 1898-99; John Hackett Walsh, L.R.C.P., L.R.C.S., Ireland; John Hanna Murray, M.R.C.S., England, L.R.C.P., London, M.B., London University, D.P.H., formerly medical officer at Isolation Hospital, Nottingham; William Samuel Jagoe Shaw, M.B., B.Ch., B.A.C., University of Ireland, formerly assistant medical officer to the Stafford County Asylum; James Harry Horton, M.R.C.S., L.R.C.P., London, Durham prizeman at Guy's in 1881; Cuthbert Christy, M.B., C.M., Edinburgh, who served as senior medical officer in African Field Force, Nigeria; John Edward Sandilands, M.B., B.C., Cantab., M.R.C.S., England, L.R.C.P. London, formerly senior house-surgeon at the Metropolitan Hospital; George Taylor, M.D., Aberdeen, B.Sc., Edinburgh, who took the public health medal at Edinburgh in his year; Harry Cogill, M.R.C.S., England, F.R.C.P., London; Edward Head Moore, L.R.C.S., Edinburgh, L.S.A., London, medical officer Falmouth and surgeon-captain in the Army Medical Reserve; Percy Targett Adams, L.S.A., M.R.C.S., D.P.H., England, *pro tem.* resident medical officer to the General Post Office, London; Mark O'Brien, L.R.C.P., L.R.C.S., Edinburgh, L.F.P.S., Glasgow, who was this year on the West London Hospital course; and Alexander Macbeth Elliott, M.B., C.M., Edinburgh.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

REPRINTS.—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them, at half the usual cost, on application to the printers before the type is broken up.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

MR. W. S. BOYD.—In reply to our correspondent's inquiries the following works will be found reliable on the subjects indicated:—(1) Hutchinson's Syphilis, 9s.; Drysdale's Syphilis, 5s.; or the American Text-book, by Bangs and Hardaway, 42s. (2) Shield's Clinical Treatise on Diseases of the Breast, 15s. (3) A Physician's Sermon to Young Men, 1s. (4) Allingham's Diagnosis and Treatment of Diseases of the Rectum, 12s. 6d., all or any of which can doubtless be had in his neighbourhood of Messrs. Baillière, Tindall, and Cox, King William Street, Strand.

DR. J. STEWART.—If our correspondent will supply us with reliable data, we shall be pleased to investigate and to state our opinions.

A PROVINCIAL PRACTITIONER will find the subject is handled in a leader in our present issue.

FRIEND MANOR.—The accused is an LL.D., not a doctor of medicine. Unfortunately the public immediately jump to the conclusion that every "Dr." mentioned in the newspapers belongs to the medical profession.

INQUIRER.—Burning of the skin by the X-rays has been found to be due, not to the rays themselves, but to a high-tension induction current formed near the Crookes' tube.

MR. WILSON is thanked for his note. A discussion, however, at the present moment would be inopportune.

AGE AND SLEEP.

TESLAU says that negroes live to advanced age because they sleep so much. He believes that a man has just so many hours to be awake; and that the more of them he uses up in a day the shorter his life will be. A man might live to be two hundred if he could sleep most of the time. The proper way to economise time, therefore, is to sleep whenever there is nothing better to do.

A THIRD YEAR'S MAN.—The results will not be known before the end of October.

INCONTINENCE OF URINE IN ELDERLY OR NERVOUS WOMEN.—When there is a frequent desire to pass water, or it runs away in the act of coughing, sneezing, or laughing, it is generally due to the want of power in the vesical sphincter. In such cases tincture of cantharides will be found of the greatest service if given in small doses of one minim in water three or four times daily.

A NEW FEATURE IN BACTERIOLOGY.—One of our non-medical contemporaries is responsible for the following:—Mrs. Malaprop's country visitor had a sore back, and her kind hostess insisted on her seeing a distinguished bacteriologist, because, as she said, she had heard so much about recent advances in bacteriology that she felt sure he would do her friend good.

Vacancies.

Athy Union.—Analyst to the Board of Guardians.—Applications to the Clerk of Union.—(See advert.)

Barrow House Hospital for the Insane, Gloucester.—Junior Assistant Medical Officer. Salary commencing at £120 per annum, with board, &c.

Cambridgeshire, &c., Lunatic Asylum, Fulbourn, near Cambridge.—Assistant Medical Officer. Salary, £140 per annum, with board, lodging, and attendance in the Asylum.—Applications to the Clerk to the Visitors, Cambridge.

County Asylum, Prestwich, Manchester.—Assistant Medical Officer, unmarried. Salary commencing at £125, with board, apartments, washing, &c.

Cumberland and Westmoreland Asylum, Gariolds, Carlisle.—Junior Assistant Medical Officer, unmarried. Salary £100 a year, with board and residence.

Devon County Asylum, Exminster.—Two Assistant Medical Officers. Salary commencing at £120 per annum for the first, and for the second £100, with, in both cases, board, lodging, and washing.

Durham County Asylum, Winterton, Fairhill.—Assistant Medical Officer, unmarried. Salary commencing at £140, with board, lodging, washing, and attendance.

French Hospital and Dispensary, 172 Shaftesbury Avenue, London.—Resident Medical Officer, unmarried, speaking French. Salary £80 per annum, with full board.

Great Yarmouth Hospital.—House-Surgeon. Salary £90 per annum, with board, lodging, and washing, and £10 extra for Govan District Asylum, Crookston, near Paisley. Junior Assistant Medical Officer. Salary commencing at £100 a year, with rooms, board, attendance, and laundry.

Manchester Clinical Hospital for Women and Children, Park Place, Cheetham Hill Road.—House Surgeon. Salary, £80 per annum, with apartments and board.—Applications to the Secretary, 38 Barton Arcade, Manchester.

Metropolitan Asylums Board.—Two Assistant Medical Officers at Darenth Asylum, near Dartford, Kent, and one at the Leavesden Asylum, near Watford, Herts. Salary, £120 per annum, rising, conditionally, to £150, with board, lodging, attendance, and washing, subject to statutory deductions. Apply at the office of the Board, Norfolk Street, Strand, London. (See advert.)

Stoke-upon-Trent Union.—Resident Medical Officer for the Workhouse. Salary commencing at £100, with board, washing, and furnished apartments.—Apply to the Clerk, Union Offices, Stoke-upon-Trent.

West Riding Asylum, Menston, near Leeds.—Fourth Assistant Medical Officer. Salary commencing at £100, with board and apartments.

Appointments.

CLARKE, H. W., M.D. BRUX., L.R.C.P. Lond., M.R.C.S., Medical Officer for the No. 1 Relief District, Kensington.

ELMES, T. FRANCIS, L.R.C.S., L.R.C.P. Edin., L.F.P.S. Glasg., Resident Medical Officer to the St. Pancras Hospital, London, N.W.

ENSOR, E. T., M.D. Univ. N.Y., L.R.C.P. Ire., L.F.P.S. Glasg., Medical Officer for the Workhouse for Able-bodied Men and for the Casual Wards, Kensington Union.

FARRAR, E. A., M.D. Oxon., L.R.C.P. Lond., M.R.C.S., D.P.H. Cantab., has been appointed under the Indian Government to take up Plague Duty.

GAMBLE, M. F. H., L.R.C.P., L.R.C.S. Edin., L.R.P.S. Glasg., Acting Medical Superintendent, *pro tem.*, for the Sunbury Lunatic Asylum, Victoria, Australia.

LOFT, ARTHUR GEORGE BATEMAN, L.S.A. Lond., Medical Officer for the Chudleigh District of the Newton Abbot Union.

ORMEROD, E. W., L.R.C.P. Lond., M.R.C.S., Medical Officer for the Southam Workhouse and Sanitary District of the Union.

WILSON, A. GARRICK, B.A., M.B. Cantab., M.R.C.S., L.R.C.P. Lond., House Surgeon to the St. Mary's Hospital, London.

Marriages.

DOBIE—MORRELL.—On Sept. 8th, at All Souls', Belvedere, William Henry Dobie, M.B., C.M. Edin., M.R.C.S., son of William Murray Dobie, M.D., of Chester, to Alice Fanny, younger daughter of Commander George Trueman Morrell, E.N., retired, of Belvedere, Kent.

HERON—BOWLEY.—On Sept. 12th, at the Parish Church, Downpatrick, co. Down, J. Matthews Heron, M.D., of Downpatrick, to Annie Margaret Warner, eldest daughter of Lieut. Colonel P. F. Bowley (late 48th Regiment), Rathdune, Downpatrick.

REYNOLDS—ALLETSON.—On Sept. 14th, at St. Luke's Church, Liverpool, Cecil Arthur Reynolds, M.B., B.Ch. Oxon., eldest son of Henry Reynolds, J.P., of Norton Lodge, Halton, Cheshire, to Elizabeth, eldest daughter of Samuel Alletson, of Liverpool.

SCHARLIEB—TWEEDY.—On Sept. 14th, at St. Andrew's Church, Redruth, Cornwall, Herbert Johann Scharlieb, M.D. Lond., F.R.C.S. Eng., second son of the late William Mason Scharlieb, Esq., of the Middle Temple, barrister-at-law, and Mrs. Mary Scharlieb M.D., M.L. Lond., of London, to Edith, elder daughter of Charles Tweedy, Esq., of Redruth.

YOUNG—CHAPLIN.—On Sept. 16th, at St. Jude's Church, South Kensington, Hy. W. Pennyfather Young, B.A., M.D. Cantab., M.R.C.S., son of the late Thos. Young, of Eastbourne, to Constance, daughter of the late James H. Chaplin, of Lloyd's.

Deaths.

BUDD.—On Sept. 13th, at his residence, 8 Gay Street, Bath, Samuel Punnett Budd, M.R.C.S., L.S.A., aged 55 years.

EZARD.—On Sept. 10th, Helen Mary Ezard, wife of Edward H. Ezard, M.D., D.Sc., of Lewisham High Road, S.E., entered into her rest, aged 37 years.

INFLUENCE OF POSITION ON THE FORM AND DIMENSIONS OF THE PELVIS. (a)

By PROF. E. PINZANI, M.D.,

of Pisa.

WALCHER'S paper, published in 1889, on the variability of the conjugata vera, being of practical interest, gave a new direction to previous researches on the mobility of the pelvic articulations, I feel obliged to state here, that according to some authors, the merit of having made practical use of the current ideas concerning the mobility of the pelvic articulations is not due to Walcher, the position he describes having being recommended in difficult labours, by Scipione Mercurio (1595) according to some, by Sebastian Melli (1721) according to others. Allowing the question to pass whether Melli might possibly have copied the design of Mercurio, I wish to observe that neither the one nor the other can have had in view enlargement of the pelvic dimensions, as in their day the mechanism of the sacro-iliac articulations was unknown. Moreover it ought to be said that though the positions described by Mercurio and Melli have some analogy with Walcher's, there is nevertheless a fundamental difference, as in the former the lower extremities of the woman are always supported, whilst in the latter they are hanging, and by their weight draw the anterior pelvic ring downward and forward. I have examined sixty-two women during the puerperal state, successively in Melli's and in Walcher's position. In seventeen cases exact mensuration of the diagonal conjugata gave no difference, in the other forty-five cases there was a difference from 1 to 8 millimetres in favour of Walcher's position. Researches on five feminine cadavers gave the same result for the conjugata vera. Therefore I think, and Pestalozza is of my opinion, that the position with hanging thighs ought to bear Walcher's name.

Changes in the pelvic dimensions. Antero-posterior dimensions.—When a woman is placed on a table, with the head and shoulders slightly elevated and the buttocks somewhat projecting beyond the edge, a cushion being placed under the sacrum, the thumbs being placed on the superior iliac spines, whilst an assistant places the lower extremities first in the lithotomy and then in the horizontal position, finally abandoning them to their weight, the following is observed:—

The iliac spines describe part of a circle in a forward and downward direction, the lumbar lordosis increasing at the same time. Moreover when the lower extremities are in complete extension and allowed to hang downwards, the iliac spinal action continues without the lumbar lordosis being further

increased. There is first an increase of pelvic inclination, limited by the tension of the ligamentum longitudinale anterius and the intervertebral joints. By this tension the sacrum is fixed. The anterior pelvic arch being drawn further downward, the effect will not be perceived for the entire pelvis, but only for the iliac bones, without change of place in the sacrum. The transverse axis for the moment of the iliac bones lies behind the second sacral vertebra. This axis being situated under the promontory, the symphysis must be removed from the promontory by the rotation, whilst it approaches the point of the sacrum; the sagittal diameter of the brim being consequently increased and that of the outlet diminished. This action of the iliac bones is limited partially by the sacro-iliac articulations, partly by the posterior ligament, and somewhat by the muscles of the abdominal wall and by the psoas.

I need not say that pregnancy will be, generally, favourable to this dislocation of the iliac bones, but I ought to add that individual conditions may diminish, even in pregnant women, this mobility.

At the present moment there is no doubt that the conjugata vera increases progressively, when the woman is brought successively in the lithotomy position, the obstetrical position and Walcher's position. Difference of opinion exists only as to the degree of the augmentation. According to the researches of Walcher, Duhrssen, Fothergill, and Küster, the increase of the conjugata varies from 8 to 15 millimetres. Of those who object to those elevated cyphers, I quote Varnier, who says that there ought not to be a comparison made between the dimension found in the lithotomy position, never used in obstetrics, and that of Walcher, but between the measures found in the latter and in the obstetrical position. In this way an increase of 2 or 3 millimetres ad maximum can be obtained, according to his researches. Later experiments of Fehling contradict partially Varnier's pessimism. The results of cadaver-experiments by Walcher, Klein, Varnier, and Pinard, and Küttner being incongruous, and on the other hand the clinical observations of Kalt, Wehle, and others showing a considerable increase, I resolved to make some researches for myself.

In 102 women, nearly all in the second week after confinement and the others in an advanced state of pregnancy, I have measured with the finger with the utmost exactness, the diagonal conjugata in the lithotomy position, in the obstetrical position, and in Walcher's position. By the change of the first position into the third I have found an increase in the average of 7.5 millimetres maximum 17, minimum 2 mm. Between the first and the second position the difference was on the average 1.9, maximum 0 mm. Between the second and the third position (101 cases) the average of the increase was 6.1, maximum 12, minimum 2 mm.

The mensuration in the five female bodies gave smaller differences.

Is it true that the increase of the conjugata vera

(a) Abstract of paper read before the International Gynaecological Congress, Amsterdam, August 1899.

corresponds exactly to that of the diagonal conjugata? According to Klein the *c. vera* is less, according to Küttner more increased than the diagonal conjugata. In the five bodies I examined the difference between conjugata vera and *c. diagonalis* was the same in all three positions.

I do not exactly know why in the corpse the effect of the alteration of position is less than in the living.

My researches confirm the results of Klein, that in contracted pelvis the difference between the length of the diagonal conjugata in the obstetrical and in Walcher's position is on the average 8.7 mm. *i.e.*, superior to the general average difference (6.1 mm.).

Moreover I found a great variety, from one case to the other, in the degree of the increase.

The *coccy-pubic diameter* will, as I have mentioned, be shortened in a higher degree than the conjugata increases. I do not know whether exact mensurations of this diameter have been made, except those of Küttner and those I have communicated at the Fifth Congress of the Italian Obstetrical and Gynecological Society. I have been able to continue these researches, and in the five corpses I examined I saw by changing the lithotomy into the obstetrical position, an average diminution of the coccy-pubic diameter of 5.6 mm., and of 9.2 mm. by changing the latter position for that of Walcher. The entire difference between the two extreme positions was thus on the average 14.8 mm., and has varied between 26 and 9 mm.

I need not say that the *antero-posterior diameter of the wide part of the excavation* does not or almost not change.

Transverse diameter of pelvis.—Küster thinks that the movement executed by the sacrum is exactly the contrary to what has been observed in rachitic pelvis, and conforming to this idea he says he has observed a diminution of the distance of the iliac spines. I have examined in regard to this point 127 women in the puerperal state, and found that by Walcher's position this distance and that of the *cristæ* was not altered in 24 cases, was diminished in 22 and increased—average 5 mm.—in the other 81 cases. The experiments on the five corpses gave the same results. Contrary to Küster's opinion I believe that the action of the sacrum is not exactly opposed to that which occurs in rachitic pelvis. In Walcher's position the postero-inferior part of the iliac bones is drawn towards the median line and the postero-superior part must make a movement in the inverse direction. By this movement there must be a tendency to increase the transverse diameter of the brim. And really, my mensurations in five cadavers, have given by the change of the lithotomy position into that of Walcher, an increase of this diameter of 3.2 mm., on the average, 4 mm. in maximum, 2 mm. in minimum. My results are thus in contradiction to those of Klein.

Variations of the form of the pelvic cavity.—After my five cadaver mensurations I have constructed a design of the schematical form of the pelvic cavity, in sagittal sections, in the lithotomy position and in that of Walcher.

I shall not speak of the practical consequences of these considerations because they are clear enough, having moreover mentioned them in my paper read at the Fifth Congress of the Italian Obstetrical and Gynecological Society.

THE professorship of Ophthalmology in the Egyptian Government School of Medicine at Cairo is now vacant. The appointment carries with it the surgency to the Kasr-el-Ainy Hospital, and is likely to have many applicants. Particulars will be found in our advertising columns, or may be obtained of Mr. Hallett at the Examination Hall, Savoy, London.

ACUTE INFECTIVE ARTHRITIS AND CELLULITIS.

By JOHN O'CONOR, M.A., M.D., T.C.D.,

Senior Medical Officer, British Hospital, Buenos Ayres, Argentina.

In my first paper (1) on this subject, I suggested the expediency of substituting the term Acute Infective Arthritis for Acute Articular Rheumatism, as I contended that the latter was not consistent with the pathology of the disease, which in my opinion is an infective malady very analogous to gonorrhœal arthritis and pyæmia.

In more recent papers (2) I adopted the heading Acute Infective Arthritis and Cellulitis, for I found in some cases on which I have operated, that there was considerable cellulitis around such points as the ankle, wrist, and phalanges without any sign of arthritis after arthrotomy. Since those papers were published I have had the opportunity of finding both conditions co-existing in the wrists and ankles.

In a recent series (3) of twelve unselected consecutive cases of "acute rheumatic arthritis" incision, with irrigation and drainage, immediately cured the local trouble, and, moreover, caused prompt subsidence of the general toxæmic symptoms.

Being the first surgeon who advocated and practised arthrotomy in gonorrhœal (4) and "acute rheumatic" arthritis, I was anxious to hear what results this treatment would give in other hands, and I was gratified in seeing (5) that Dr. John Homans had found it most satisfactory in a case of gonorrhœal arthritis. So far as I am aware, no other surgeon has tried it in "acute rheumatism," but I was pleased to read a temperate criticism (6) of my paper (7) by Dr. Ewart, in which he admitted that there are some cases which do not respond to the "usual treatment," and that "the so-called rheumatic cases fall into two clinical groups, those which promptly recover under the usual treatment, and those which do not." In making this statement, Dr. Ewart has obviously struck a keynote, *viz.*, that the second group cannot be diagnosed until after a useless and positively detrimental treatment has had a trial, not to mention loss of valuable time.

Even admitting the empirical existence of two such groups, the question naturally arises, does metastatic endo or pericarditis ever supervene in cases where only one joint, or two symmetrical ones, are attacked? From an experience of twelve years' hospital practice, I can certainly answer this in the affirmative. In fact, the worst case of "rheumatic" endocarditis I have ever seen occurred in a patient who had only both knee-joints affected.

Dr. Ewart suggests the term, "for want of better," "acute rheumatoid arthritis." What purpose the meaningless word "rheumatoid" can serve I fail to comprehend, unless to mystify our sense of perception.

If anyone is interested in my views as to the pathology and treatment of this common complaint, I should like to refer him to the "Annals of Surgery," February, 1898, and April, 1899.

The two following cases, which are at present under treatment, tend to prove the practical truth of the above statements.

CASE XI.—P. G., married man, labourer, æt. 34, was admitted to hospital on July 18th, complaining of pain in the left ankle and both shoulder-joints. Temp. 103.4 degs., pulse 80, tongue furred, profuse perspiration, urine scanty, high coloured, no albumen, lungs and heart normal; with a history of rheumatic fever two and a half years ago.

July 19th. Left ankle became swollen, pains in the shoulders continued, and pain developed in left knee. Salicylate of soda, grs. xx, ordered ever

three hours, joints enveloped in warm wool, and sheets removed from bed. Milk diet and a saline purge.

20th.—Left ankle more swollen, red, and very painful, left knee swollen and distended with fluid.

21st.—Right ankle and right knee became swollen during the night. As patient was becoming progressively worse with both knees and ankles swollen, tender, and painful, and pain in both shoulders, with general symptoms more marked, medical treatment was abandoned.

22nd.—Arthrotomy of both knees and ankles was performed, and turbid serum removed from each, the joints were irrigated with 1 in 2,000 corrosive sublimate lotion, drainage tubes inserted into knee-joints, and sterilised gauze into ankle-joints. As considerable cellulitis existed on the dorsum of feet free incisions were made into affected areas, and wounds irrigated and stuffed with gauze. Although pain was complained of since admission in both shoulders I refrained from opening the joints, as I hoped the removal of the toxin from the other joints would effect a cure.

Second morning, temperature had fallen to 99 degs., sweating had ceased, and patient expressed himself as absolutely free from the former pains, excepting an occasional twinge in the shoulders.

Fourth morning, temperature remained normal, general symptoms had completely vanished, drains removed, free action movement of each joint without pain; as patient complained of hunger full diet was ordered. An uneventful convalescence ensued, and he was allowed out of bed as soon (August 14th) as wounds were sufficiently healed.

CASE XII.—J. B., *et.* 37, coachman, became suddenly ill on July 14th, with shivering, fever, and pains in shoulder and left knee. On examination he had temperature 102.3 degs., profuse sweating, dirty tongue, high coloured, scanty, non-albuminous urine, pulse 100, and loss of appetite. The left knee was painful to touch, but no swelling was found in it or shoulders, lungs and heart normal. "Rheumatic fever" being diagnosed, soda saylic, *grs.* xx, was given every three hours, and warm wool and blankets applied.

July 16th.—Left knee-joint swollen and distended, temperature reached 102 degs. each night, with a slight morning remission, pains continued in shoulders, general condition worse; treatment continued as before.

22nd.—Swelling, tenderness and pain of left knee increased, some swelling noticed on the palmar surface of metacarpo phalangeal joint of right middle fingers, and a coarse friction sound elicited for the first time, on auscultating præcordium. Patient looked very ill, with face flushed, pulse 110, temperature 103 degs., respirations 34, and he had no desire for nourishment. Six-hour hypodermic injections of strychnine and digitalis ordered.

24th.—As the condition was becoming grave, medication was given up and arthrotomy of left knee performed, and eight ounces of turbid serum evacuated. The joint was irrigated and a large drainage tube inserted. Two incisions were made into swelling in finger, serum oozed from the cut surfaces, and sterilised gauze was placed in wounds.

25th.—All pains had departed, sweating ceased, temperature 100 degs.; patient appeared a different being.

August 1st.—Pericardial friction sound less distinct; temperature reaches 100 degs. at night, and falls to normal each morning. Knee normal in contour, no pain or tenderness on manipulation, active movement through a right angle. Middle diet asked for, and given.

7th.—No abnormal sound found on auscultating cardiac area. Temperature remained at normal. Patient able to sit up in bed and partake of full diet.

Convalescence was rapid, and he was allowed out of bed with his colleague on August 14th.

In both these cases I forgot, in the hurry of concluding operation, to insert waiting silkworm-gut sutures, which I have frequently found most useful in accelerating the healing of knee wounds.

In conclusion, I wish to lay particular stress on a most important detail in the operation. Take care to establish thorough drainage, for an open non-draining knee-joint is a terrible surgical precipice. In order to avoid risk the joint capsule should be freely incised, and a well perforated drainage tube of at least one-third of an inch in diameter inserted into synovial pouch.

Given ordinary cleanliness and free drainage, arthrotomy (8) is one of the most simple and safe procedures in surgery, and rarely takes me more than five minutes to perform.

Finally, in the disease acute infective arthritis and cellulitis, do not wait for a cardiac murmur to confirm the diagnosis; operate immediately effusion is detected in a joint or joints. By so doing, metastasis can be certainly prevented.

A PLEA FOR MORE EXTENSIVE OPERATIONS IN THE TREATMENT OF MALIGNANT DISEASE OF THE JAWS. (a)

By J. PAUL BUSH, M.R.C.S.,
Surgeon, Royal Infirmary, Bristol.

THE following cases of malignant disease of the jaws are, I think, interesting, not only on account of the magnitude of the operations, but also because they were looked upon by some as cases too extensive for operative interference.

M. W., a young woman, *et.* 16, was sent to me for consultation at the end of last year. Some nine or ten months before she noticed pain in the upper jaw, and a month or so later her friends noticed that the upper lip appeared swollen. The upper jaw was enlarging in size, but the pain ceased.

Six weeks previously she had been admitted into a hospital, where a small tumour the size of a hazel nut had been removed from the left of the middle line. The operation wound had healed, but at the end of a couple of weeks the tumour was seen to be growing again, and now rapidly. The growth had been examined microscopically, and diagnosed as sarcoma. Four weeks after this first operation she was seen at the same institution, when the tumour was growing so rapidly that it was decided that nothing more could be done. When she came under my notice there was a moderately firm swelling situated more to the left but invading also the right superior maxillary bone, extending from above the first left molar, across the middle line to above the first right bicuspid tooth. This growth pushed forward the nose, and extended into the mucous membrane of the floor of both nares, which were considerably narrowed. There was also marked bulging down of the palate on the left side. The tumour was not growing from the margin of the

(a) Abstract of paper communicated to the Surgical Section, Portsmouth meeting, British Medical Association, August, 1899.

gum and the teeth, but appeared to grow from within the antrum. I kept her under observation for ten days, as it was thought we could do very little for her, during which period the swelling increased in size, the teeth became loose, and pain became extreme. At the earnest request of herself and her friends I decided to operate, this I did by the usual incisions on each side of the nose and division of the lip, after cutting through the vomer I was able to turn the nose upwards; I then sawed through the lower portions of the nasal processes downwards and outwards to immediately in front of the first molar on each side, having previously cut through the mucous membrane of the palate with the knife, I chiselled through the line of articulation of the palate with the superior maxillary in the mouth, and so removed the bodies of both superior maxillary bones together with the tumour.

There was considerable hæmorrhage, which was stopped by a large plug of iodoform gauze. The nose was fixed into position, and the divided lip sutured.

She made an uninterrupted recovery, and went out of hospital the end of February. About three weeks after operation my colleague, Mr. W. R. Ackland, made her a temporary upper jaw. This she only wore for some hours in each day to prevent the upper lip and nose from falling in. In March last there was no sign of any recurrence, and I re-divided the upper lip and performed a modified operation as for hare-lip, as the mucous membrane had been drawn upwards by the cicatricial tissue. An excellent permanent jaw with teeth was now fitted by our dental surgeon, and, thanks to his manipulation, the girl's appearance is so good that she has obtained a situation in a fashionable drapery establishment in the West of England. Very few would notice anything wrong in her appearance.

Under the microscope the tumour is evidently a rapidly growing small spindle celled sarcoma.

This case at any rate to me is most instructive, as it was doubtful whether one ought to attempt removal. So many months have now passed and the patient is so well that there is every reason to believe there will be no recurrence.

J. J., a man, æt. 60, came to see me at the Bristol Royal Infirmary in April, 1899, with a history of a sore tongue for six months. He had seen several doctors but they all advised him that nothing could be done to relieve his cancer, as it was too far advanced.

When I saw him an extensive epitheliomatous growth involved the anterior half of the tongue, and the whole of the floor of the mouth. Both sub-maxillary glands were affected, and there was a large mass of glands leading from these into the lymphatic glands of the neck on both sides.

The pain was extreme and the patient could not talk or move his tongue, and could swallow liquids only with great difficulty. Under chloroform I made a central incision through the lower lip down to the hyoid bone and then carried it horizontally on each side of the neck to just below the angle of the jaw. By these incisions I was able to tie the first one and then the other lingual artery close to the hyoid bone. I then sawed through the lower jaw on each side in front of the angle, and, having tied several vessels in this position, I cut away the entire tongue from its attachments to the epiglottis and, cutting freely with the scissors, cleared the muscles attached to the hyoid bone, thus taking away the body of the jaw, to which was firmly attached a large mass of infected salivary and lymphatic glands on each side of the neck. I further cut away all doubtful tissue and skin. At this stage of the operation considerable difficulty was experienced on account of the patient ceasing to breathe; but this was remedied by passing a silk suture through the

soft parts immediately in front of the epiglottis, and by an assistant holding it forwards and upwards. A large number of vessels were ligatured and the remaining skin was brought together in the middle line and sutured, a large tube was placed in the cavity and brought out immediately above the hyoid bone. Thus the whole of the tissues above the level and the hyoid bone as far as the epiglottis posteriorly were removed.

On being put to bed it was found that the glottis became closed unless dragged forwards continually. My dressers remained for some hours with the patient gently pulling on the silk suture above referred to.

The patient was carefully fed with a tube, and no nourishment was allowed to get into the mouth cavity.

The difficulty in the breathing ceased by the end of 48 hours, and in less than three weeks he was being fed with soft solids, and he went home some six weeks after operation.

He came a four hours journey to see me a few days ago, when he told me he was as "jolly as a sandboy," and doing some work. He has grown a moustache and beard, which helps to hide his deformity. There is as yet no sign of recurrence; he is absolutely free from pain, and is talking fairly distinctly. He has put on two stone in weight, and taking plenty of nourishment. He says he much prefers feeding himself with a short tube, as it makes him cough sometimes when he feeds without one. Under the microscope the growth is a typical epithelioma. In this case it is as yet too soon to imagine it will not recur, but even should it do so, we have given this man some months of comfortable life.

CARDIAC OVERSTRAIN IN THE YOUNG. (a)

By F. J. POYNTON, M.D.,

Casualty Physician to St. Mary's Hospital; Clinical Assistant to the Hospital for Sick Children, Great Ormond Street.

In this paper Dr. Poynton considered some of the problems that arise when dealing with the question of athletics as a cause of cardiac overstrain. The subject, one of growing importance, was by no means easy to investigate, because of the difficulties that surround accurate observation, and there was for this reason a danger on the one hand that an alarmist view might be taken of the question, and, on the other, that the damage that prolonged physical strain entailed upon the heart might be underrated. If, for example, a man who had been a good athlete and still took part in competitive exercises consulted a doctor for symptoms which were referable to the heart it was at once apparent how difficult it must be to estimate the actual part taken by the physical exertion, and if there be no valvular murmur the actual condition of the heart. Da Costa, Professor Clifford Allbutt, and others had contributed important clinical facts upon this subject, but there was still of necessity a lack of accurate knowledge upon the question.

Dr. Poynton then described some investigations that he had made at one of the large public schools by the following method. The subject lay upon the back with the left arm slightly abducted, and the deep cardiac dulness was percussed out and delineated upon the chest wall with a dermatographical pencil. The position of the impulse was noted, and any murmur or accentuation of sounds recorded, and the result transferred to tracing paper. This paper was then named and dated after the following land-

(a) Abstract of a paper read before the British Medical Association at Portsmouth, August, 1899.

marks had been made: the left nipple, the midsternal line, and xiphisternal notch. Finally, the pulse-rate and any peculiarities either of the chest or general physique were registered upon the paper, which was then preserved as a permanent record. Advantage was taken of the fact that the foot-races were held at the end of the Lent term, and fifteen likely athletes were examined upon the 6th of February, and upon the 6th of April, the day after the final heats nine of these boys were re-examined. The author pointed out that the results were too few for definite conclusions to be drawn, but the method appeared to be one that might be of considerable value, especially if applied to adults who were passing their athletic prime; that is at the time when pathological evidences would be most likely to become manifest.

It was of interest that in none of these cases was there any tachycardia, though in several an enlargement of the heart to the right and to the left and upward was apparent.

Dr. Poynton then briefly considered the question of athletics at the great schools. In some cases there were boys who could not possibly indulge in the games, but there were also some of the more weakly boys whose games were curtailed rather than stopped. It was to this question of curtailing games that he drew especial attention, as being one of much difficulty and importance. It necessitated an accurate knowledge of the exertion value of the chief games, which he ventured to think was not possessed sometimes even by experts upon diseases of the heart. It was important, because athletics took a very prominent part in a boy's life, and to interfere with them needlessly was to interfere with much of his life at school. It was difficult, because all the ordinary school games, if played well, involved considerable exertion, and advice to play them badly could hardly be given. The competitive exercises, running and the like, were violent, not only because of the continued exertion required, but because of the tendency there must necessarily be to better one's best when face to face with an equal or superior. The serious effect of such a form of exercise upon a damaged heart had been generally recognised, and was illustrated in this paper by the case of a young man, *æt* 26, who had been "out of sorts" for some days, and went for a row in a four-oar boat to shake off the malaise. On landing after this exertion he felt very ill, and died in three days with extreme tachycardia. At the necropsy Dr. Poynton found evidence of a previous pericarditis and valvulitis. Both forms of football were pointed out as violent exertions, and from the sudden strains that resulted from "tackling" liable to injure the aortic area of the heart. This danger to the aortic valves from a sudden strain, had been insisted upon by Professor Clifford Allbutt, and was illustrated in this paper by a striking case. A coast-guardaman, aged between forty and fifty, was in the habit of playing football every Saturday, and after one of these games, while sitting at home in the evening, thought he heard a steamer. He was so convinced of this that he actually went out of the house to look for her, but the sound was due not to a steamer, but to a murmur caused by a ruptured aortic valve. Hockey avoided the sudden wrenches of football, but was too fast a game for a boy with a really weak heart. Racquets and fives were not uncommonly thought to be a mild form of exertion, but in reality were if played at all well most trying, and boxing was quite out of the question. Cricket was on the whole a milder form of exercise, though fast bowling and much running between the wickets involved violent exertion. Among gymnastic exercises some were admirable as examples of graduated movements, but others such as climbing the rope, were far too severe a strain for a weak heart.

THE USE OF ANTI-STREPTOCOCCIC SERUM.

By FRANK F. BOND, M.R.C.S., L.R.C.P.,

House Physician, Westminster Hospital.

I PROPOSE to base my remarks on some cases which have come under my observation in the wards of this hospital, and I shall deal principally with the treatment of facial erysipelas, several cases of which have recently been successfully treated here by the anti-streptococcic serum. This form of treatment is now extensively used in the hospital in the various forms of streptococcus infection, and in no disease are the results more favourable than in erysipelas. The administration is commenced immediately after admission, and continued daily, usually in ten cubic centimetre doses, until the temperature falls to normal. In a moderately severe case three or four injections are generally sufficient for this purpose. The serum employed is the liquid preparation supplied by the Institute of Preventive Medicine. It can always be obtained in London at a few hours' notice either from the Institute or from any of the large wholesale druggists. It is injected with the usual antiseptic precautions, the skin being carefully washed and carbolicised and the syringe being rendered aseptic by boiling. The only local treatment employed consists in the protection of the affected part from the air by means of a lint mask, which is dusted with a powder consisting of two parts of zinc oxide and one of starch, and the patient is liberally supplied with brandy, the usual dose being half an ounce every three hours. No other medicinal treatment is used.

The notes of four cases recently treated in this manner are given below:—

CASE I.—A woman, *æt* 27, was admitted to Westminster Hospital at 4 p.m., on May 19th, 1899. She first noticed a tender swelling on the mucous membrane of the right nostril on the 17th. A few hours afterwards the outer surface of the nostril was red and swollen, and by the next morning the rash had extended to both cheeks. It continued to spread until admission. On admission there was extensive erysipelas of the face and neck. The whole face was involved, and the swelling extended upwards over the forehead as far as the roots of the hair. Both ears were affected, and the rash extended downwards into the neck as far as the level of the hyoid bone. The eyelids were considerably swollen, and partially closed. The temperature was 103 degs. F., and the patient was quite unconscious. Immediately after admission, ten cubic centimetres of anti-streptococcic serum were injected into the subcutaneous tissues of the abdominal wall, and the treatment described above was commenced. During the night the temperature ranged between 101 degs. and 103 degs. The patient was delirious and did not completely regain consciousness until five o'clock on the following morning. At 8 a.m. on the 20th the temperature had fallen to 101 degs., but during the day it rose again, and at 4 p.m. it stood at 104.4 degs. At 9.30 p.m. a second injection of ten cubic centimetres of anti-streptococcic serum was administered. The face at this time was still considerably swollen, and the eyes almost closed. The eyelids were bathed with a weak solution of boric acid. On the 21st the temperature fell to 99.8 degs., and did not at any times subsequently reach 100 deg. The swelling of the face was considerably less, and the eyes were fully open. Two more injections of serum were administered, one on the 21st and one on the 22nd. The temperature fell to normal on the morning of the 22nd, and remained at that point. On the 24th, the rash had almost entirely disappeared, and the face was desquamating in large flakes. She was well enough to get up on the 25th.

CASE II.—A girl, *æt.* 16, was admitted at 5 p.m. on May 20th, 1899. The patient had first noticed a red tender spot immediately below the left *alæ nasi* that morning. She had observed no abrasion there previously. The swelling rapidly spread to both sides of the face. On admission there was a red brawny swelling involving the nose, the upper lip and both cheeks, extending on both sides as far as the prominence of the malar bones. The nose and upper lip were much swollen, and there were a few vesicles on the *alæ* of the nose. The temperature was 100 degs. The treatment was commenced at 9.30 p.m. on the 20th, ten cubic centimetres of serum being injected. The temperature at that time was 100.2 degs. On the morning of the 21st the temperature had fallen to 98 degs. At noon a second injection of the serum was given. The temperature at midnight rose to 99.2 degs., but fell next morning to normal, and did not subsequently rise above 99 degs. A third injection was administered on the 22nd. On the 24th the nose was still a little swollen, otherwise the rash had disappeared. Slight desquamation was taking place along the edges of the *alæ nasi*, the rest of the skin was normal. She was able to leave her bed on the 25th.

CASE III.—A man, *æt.* 36, was admitted at 4 p.m. on June 3rd. He noticed pain and swelling of the left cheek at about 3 p.m. on June 2nd. The swelling rapidly extended over the greater part of the face. On admission the whole of the left side of the face was involved, and the rash had extended across the middle line as far as the prominence of the right malar bone. He said he felt drowsy, and complained of a tingling sensation in the face. The temperature was normal. Ten cubic centimetres of anti-streptococcic serum were administered at 5.30 p.m., and the patient was treated in the ordinary way. On the 4th the face was still considerably swollen, and the left eye partially closed. He vomited once in the early morning. The temperature rose in the afternoon to 99.2 degs., but dropped to normal in the evening. He still complained of feeling drowsy. No more serum was administered. On the morning of the 5th the rash was subsiding, and the eye was fully open. He stated that he felt quite well. Desquamation had commenced. By the 7th his face was normal, and he left the hospital on the 9th.

CASE IV.—A man, *æt.* 48, was admitted to the surgical wards on May 10th, 1899, suffering from right-sided mastoid abscess, which had perforated the bone and extended down into the neck, for which he was operated on by Mr. de Santi. He stated that seven weeks before admission he had erysipelas of the right cheek. He did very well until the evening of May 29th, when his temperature suddenly rose to 103 degs. It came down to normal, however the next morning, but on the 31st it rose to 101.6 degs., and on June 1st to 102 degs. During that day he complained of tingling in the left cheek, and on the following morning there was well-marked erysipelas on the left side of the face, apparently having no relation to the operation wounds, which were on the right side. He was transferred to the isolation wards on June 2nd, and at 5.45 p.m. ten cubic centimetres of anti-streptococcic serum were administered. The temperature at that time was 103.2 degs., and the pulse rate 120. There was a deep red blush on the left cheek, and the left side of the face, and a lighter red discolouration over the whole left side of the face, extending up into the scalp, and also across the middle line to the right side of the face and neck. There was very little discolouration in the neighbourhood of the operation wounds, and the wounds themselves looked healthy. There were patches of redness all over the back, extending down to the lumbar region. The patient was delirious

during the early part of the night. A hypodermic injection of a quarter of a grain of morphine with atropine (*gr.* 1-120) was given at 12.30. He slept well until 5 a.m. when he was quite rational, and said he felt much better. The temperature at 11 a.m. on the 3rd had fallen to 99.2 degs., the pulse rate being 100. The face was in much the same condition as the night before. The patches of redness had disappeared from the back below the angles of the scapulae. A second injection of serum was given at 11 a.m.

On the morning of the 4th the temperature had fallen to 97.8 and the pulse rate to 96 degs. The face was less swollen and not so red. The rash had almost entirely disappeared from the back. At 6.30 p.m. on that day the temperature suddenly rose to 101.6 degs. Ten cubic centimetres of serum were given at once, and the temperature fell again, standing at midnight at 99.2 degs. Next morning it was 97.4 degs., and did not at any time subsequently rise above normal. From that time the patient improved rapidly, and the rash had entirely disappeared by the 8th. Desquamation continued for four or five days after the disappearance of the rash.

The success of the treatment in these cases is very marked, especially in Cases 1 and 4; the disease in these cases was very extensive, and the constitutional symptoms were severe, but within a few hours of the administration of the first dose the temperature was considerably reduced, and the patients expressed themselves as feeling much better, and three or four doses were sufficient to overcome the disease. It may be mentioned that the injections did not cause any cutaneous symptoms, such as are sometimes seen after the administration of the anti-diphtheritic serum, with the exception of some slight tenderness at the point of inoculation, which passed off without treatment in the course of a few hours. The site chosen for the injection was the subcutaneous tissue of the anterior abdominal wall, in the iliac region.

The serum has also been used in other suppurative and pyæmic processes, with varying success; in some cases no benefit whatever has been obtained from its administration. But in these cases it is necessary to remember that the anti-streptococcus serum is only claimed to be of value in cases of streptococcus infection, and that it will obviously be of no service in diseases due to the presence of other organisms. A case in point occurred at this hospital a few weeks ago. A woman was admitted suffering from ulcerative endocarditis, following parturition. On admission her blood was examined bacteriologically and found to be sterile. Anti-streptococcic serum was administered every day for a fortnight, but with no signs of improvement. Subsequently her blood was examined a second time, and the presence of staphylococci was demonstrated. No streptococci were found. In this case the anti-streptococcic serum could not be expected to produce any benefit, seeing that the disease was due to other organisms. It is therefore advisable, before pronouncing this method of treatment to be a failure, to make sure that the disease for which it is used is due to the presence of streptococci; but it is not necessary to wait for the result of the bacteriological examination before commencing the treatment, as by so doing the disease is allowed to progress, and the chance of saving the patient's life may be lost, whereas, even if the injection do no good, it does not appear to produce any ill effects.

It is understood that Dr. Moorehead has withdrawn his candidature for the Professoriate of Medicine in Queen's College, Belfast, vacated by the death of Dr. Cuming, and that Dr. Lindsay, who has been temporarily doing the duty, will "walk over" for the appointment.

RECRUDESCENCE OF PLAGUE IN THE EAST.

By PROFESSOR W. J. SIMPSON, M.D., F.R.C.P., D.P.H.

THE sudden disappearance of plague from Europe is not to be accounted for by the commonly-received view that it was due to advancing civilisation. The absence of plague—even for a long period—is no absolute proof of the immunity of the locality. The city of Bombay was free of plague for nearly two centuries, and yet it would be impossible to state that the city, taken as a whole, is less protected now by sanitation than it was during the two centuries, or that the people and its government are in a less civilised state. Since its appearance in China the plague—notwithstanding the slow character of its extension—has travelled a great distance. In the first two years it travelled 3,000 miles westward to Bombay, and in the next three years it continued its course at about the same rate. Since its advent plague has caused in India over a quarter of a million deaths, the worst feature being its annual occurrence. Poona was but recently in the throes of its third epidemic, over 150 of her inhabitants dying per day, which, in a town of such small dimensions, is an enormous mortality, as may be gathered from the statement that if a similar mortality prevailed in London the metropolis would lose over 10,000 persons a day. The mortality in Poona is all the more serious as, from a personal inspection of the town and of the interior of the houses, I can state that, if inefficient drainage be excepted—which allows of waterlogging of the soil—it is no worse as regards sanitation and over-crowding than hundreds of towns of a similar size in Europe, and is certainly in a much better condition than many.

The re-appearance of plague in Egypt after an absence of fifty years, with its extension into Portugal, is a matter of profound interest, because it indicates that this plague from China partakes rather of the nature of a pandemic than an epidemic, and possesses that which other plague epidemics for nearly the last 200 years have lacked, viz., the quality of diffusiveness, which defies the precautions, even as revised by the Venice Conference, and hitherto adopted against its progress. The commercial conditions in the West are more favourable to its diffusion than those of the East. No danger practically existed of plague spreading from India to Europe by sea, as the commercial intercourse between India and Europe is maintained by Europeans who belong to a superior class, and who have hitherto enjoyed an exceptional immunity from plague. The danger to Egypt of infection by plague has been not so much in its commercial relations with India but in its religious pilgrimages, which bring Egyptian pilgrims in the Hedjeiz into very close relationship with Mahomedans from infected centres. The commercial relations between Egypt and Europe are, on the other hand, of the most intimate nature, kept up by fishermen, traders, and travellers, and extending to all classes, and including those likely to be affected with the disease.

Two discoveries of the first magnitude have been made, the one by Kitasato, showing that the bacillus is the cause of the disease, the other by Haffkine proving that from this bacillus a prophylactic may be prepared which has strong protective powers. These, combined with the fact that plague is a disease which only slowly gains a firm footing in a locality renders the checking or mitigation of an outbreak more hopeful and certain than before.

The danger of extension, as in some other infectious diseases, lies in our ignorance as to medium and agents by which the bacillus gains access to the

body, causing a dependence on general rather than special measures of defence. It seems to me to be of paramount importance that the governments of those civilised countries which are affected with plague should not be content in merely endeavouring to combat the disease by every known method at their disposal, such as isolation of the sick, evacuation and disinfection of infected houses, &c.; but they should systematically, as a part of the sanitary defence of the country, establish laboratories and special departments for organised research and inquiry into the mode of spread of the disease, for it is only by the adoption of these methods that success is likely to be attained.

To the precautions advised by the Venice Conference to prevent importation, I think two others should be added, viz., use should be made of the protective power of Haffkine's prophylactic, and rats should be dealt with at infected ports, on the voyage on ships from infected ports, and on arrival in healthy ports.

In connection with the checking or stamping out of plague, when it breaks out on land, the early notification of disease is of immense advantage, for it allows measures to be early and promptly applied, so that the sick can be isolated, the inmates of the house removed and watched, and the house disinfected.

It is possible with proper organisation to deal with plague as with an outbreak of small-pox. Large supplies of Haffkine's prophylactic are necessary in order that every possible contingency may be provided against, and the preparations of these supplies, which require time and a skilled organisation, ought not to be left to the last moment to meet plague. The organisation for defence requires to be placed on as complete and in as efficient a state of preparedness in every respect as the army and navy of the country would be if there was danger of invasion. The sanitary organisation of the country inspires confidence that all will be done which our present knowledge suggests, to protect the country against disease. But, as stated previously, that knowledge is very imperfect.

In the case of an outbreak of disease, such as typhoid fever, in this country, a scientific investigation is undertaken as to its cause and mode of spread. It is known that typhoid fever is caused frequently by contaminated water. This, however, does not prevent further investigation being made in order to ascertain if any new facts can be discovered with reference to the epidemiology of the disease. A similar inquiry is certainly called for in regard to the plague, which is a disease that this generation is happily not familiar with. The importance to this country of observing its behaviour as modified by conditions in Europe is such that the study of it in its epidemiological, prophylactic, and curative aspects should be undertaken by Government. To this end it would appear to me advisable that a small commission of experts of physicians, epidemiologists, and bacteriologists should be sent to the Peninsula for that purpose. It is a matter of imperial concern and admits of no delay.

[Subsequently a resolution confirming the suggestion for an official investigation put forward by the author was unanimously adopted by the section.—
ED. M. P. AND C.]

A Case of Catalepsy.

A PUPIL-TEACHER, æt. 16, living at Rodey (France), has just recovered from a well-marked cataleptic condition lasting thirty-six days. She passed the first month at home, remaining all the time plunged in a deep sleep, and as no improvement took place she was taken to the hospital. The patient recovered consciousness within a few days of her admission, without any treatment except measures designed to reduce her comfort to a minimum, and is now convalescent.

(a) Abstract of a communication read before the Sanitary Institute, Southampton, August, 1898.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, September 23rd, 1899.

THE PATHOGENESIS AND TREATMENT OF ECLAMPSIA.

In a recent number (September 6th), I gave an account of a brochure on this subject by Dr. Siegfried Flatau, on the present occasion I propose to devote a short space to a paper on the same subject in Volkmann's *Sammlung* from the pen of Professor H. Fehling. The subject is an exceedingly important one, and up to the present advances into the etiology of eclampsia have been slow.

As regards pathological anatomy Professor Fehling says that the organs principally implicated as shown by morbid changes are the liver, the kidneys, the organs of the fœtus, and some light has been thrown on the subject by animal experiment. The liver changes are by no means constant, and where present they are very varied in kind and intensity. Kidney disease or albuminuria has almost always been found, but the form of kidney disease has varied exceedingly (acute nephritis, chronic nephritis, frequently with recent changes), and above all a striking want of proportion exists between the severity of the clinical symptoms and the intensity and extent of the kidney disease. In the case of a dead fœtus, changes in the kidneys and liver are present, analogous to those in the eclamptic mother. The urine of eclamptic and also nephritic patients is in cases of intravenous injection far more poisonous than normal urine. In the former, in many cases thromboses are caused. The serum of eclamptics has not been proved to be more poisonous than that of healthy individuals, although the contrary has been stated. From all this it follows that whilst clinically eclampsia remains one disease, the anatomical condition and experimental results in individual cases are very changing.

The French theory of a hepatic toxæmia can be as little maintained as the old French's theory of uræmia. It is not impossible that a part of the liver changes are really consequences of the violent shocks.

According to the author, in arriving at an explanation of the pathogenesis of eclampsia, too little attention has been paid to the products of conception, to the fœtus itself. He is inclined to the following view in building up the fœtus, materials and regressive metamorphoses are formed which find their way into the maternal circulation by way of the placental veins and the inferior cava; these increase the toxicity of the maternal blood and put a greater strain on the excreting organs, the liver and kidneys. It has been determined that there is an accumulation of fibre-giving material in the blood of eclamptics, of globules, as an indication of disturbed tissue change, by which the occurrence of creatine, creatinine, leucomaines, and carbamic acid can be explained. By the accumulation of globules in the blood, the epithelium of the kidney first suffers injury, albuminuria is the first symptoms of the intoxication of the pregnant system. Through this injury to the renal epithelium, further accumulation of poisons takes place, the liver participates in the injury, and at last the attacks break out. If the fœtus is the fount of the injury, the frequency of eclampsia in twin pregnancies is explained.

Prophylaxis is the chief thing, with systematic ex-

amination of the urine. If albuminuria comes on, strict rest in bed and a milk diet are the best remedies (Tarnier). According to the author's experience the attack comes on in half the cases during pregnancy; and when they once occur labour almost always comes on. Early rupture of the membranes acts favourably. The author ruptures the membranes at once after the first attack, and he is in favour of early delivery by forceps and moderate incisions with living children, and with dead by perforation. He is not in favour of Cesarean section, the less so as in a divided operation in one case the first fit came on. Venesection should be useful as it unburdens the overcharged circulation; excitation of the excretory organs, the skin and kidneys is better. He therefore injects $\frac{1}{2}$ to $\frac{1}{4}$ of a litre of physiological saline solution subcutaneously thrice daily, and applies hot wet cloths over the loins. Narcotics (morphia, opium, chloral, chloroform), if used at all, should be made use of with caution.

It is unfortunate for the practitioner that in the case of a rather frequent and very dangerous disease there should be such little unanimity as to its nature and etiology, and consequently of the correct and best treatment to be applied.

WOUND OF THE LEFT VENTRICLE—RECOVERY.

Sanitäts Rath Dr. Pagenstecker, Elberfeld, reports the following cure in the *D. Med. Wochens.*, 32/99:—

A lad of 17 was stabbed in the breast by a comrade with a dagger-like knife. The writer saw the boy half an hour after the receipt of the injury. There was deep syncope, a small punctured wound in the left intercostal space below and inside the nipple. The pulse could not be felt, there was scarcely any respiratory movement, and the conical reflex was abolished. Cardiac dulness increased to the left, the sounds were distinct but very feeble. Operation was performed sixteen hours after the injury was inflicted, by this time dulness had extended over the whole of the left chest. The fifth rib was cut down upon and a portion 6 cm. in length resected from the cartilage outwards. On enlarging the opening, the wound in the pericardium was plainly to be seen, it was smooth and sharp-edged, and was about 2 cm. in length. This opening was enlarged, and the edges held by forceps. The wound in the ventricle now became visible. It lay 3 cm. above the apex, was 3½ cm. in length, it was sharp-edged, and gaped only slightly. A small stream of bright red blood trickled out persistently. There was no or very little blood in the pericardium. Three deep sutures of celluloid thread and one superficial one were placed in position. The hæmorrhage caused no difficulty, the only one experienced lay in inserting the uppermost posterior suture, as it was only when the heart rolled forwards that it could be inserted. By this suture the heart could be drawn forwards, so that all difficulty now ceased. The deep suture did not go through the endocardium. The manipulations did not interfere with the movements of the heart. The bleeding ceased on tying the sutures. On enlarging the opening in the pleura, in order to arrest any possible hæmorrhage there, a big wave of dark fluid blood and clot flooded the field of operation, and after this came bright fluid blood. The whole thoracic cavity was quickly filled with sterilised and iodoform gauze alternately packed in, whereby at last the bleeding was stanch. The wound in the pericardium was made smaller by catgut sutures, and the ends of the sutures of

the myocardium, that had been left long, were brought out through the opening to serve as a drain. The after course was favourable. On the ninth day two sutures came away on pulling on them, and in ten days more the remainder were removed. Complete recovery took place. The operator saw the patient 10 months afterwards, and found him in good and blooming health.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, September 23rd, 1899.

OFFICIAL REPORT ON BUBONIC PLAGUE.

THE Imperial Commission appointed in 1897 to proceed to Bombay for personal examination and scientific inquiry which might guide the Austrian Government in its management of the disease, should it unhappily be conveyed to the Empire, have just issued their report in two parts. The first deals with the history of the disease, and is illustrated with five plates; the second may properly be called the scientific and experimental. On February 20th, 1897, Drs. Müller, Albrecht, Ghon, and Pöck arrived in Bombay on their scientific expedition, and, as previously arranged, proceeded at once to Arthur Road Hospital, where a temporary laboratory was arranged for local investigation.

From February to April 22nd the inquiry seems to have been of a general character, clinical and post-mortem. After this date the Commission began to collect and preserve specimens for more minute examination, histologically and bacteriologically, on their return to Vienna, which they reached on May 17th. The report goes on to record the catastrophe which occurred last year when Dr. Müller and two of the attendants succumbed to the disease. It condemns the unsuitable rooms for such pathological examination, and affirms that their half-equipped improvised laboratory in India was much superior to that of Vienna.

Dr. Müller's report consists of the clinical history of one hundred cases with detailed analyses of the urine and blood. The complex symptoms and buboes are described at great length, the latter occurring as primary lesions as well as secondary, undergoing great changes during the course of the disease. The primary fresh pneumonia cannot be distinguished from the croupous form of pneumonia. The sero-sanguinolent form of pneumonia with profuse sputum is a good augury for recovery. A thick deposit on the fauces and pharynx is also a common symptom.

Müller dissents from the older established view of the plague carbuncle and cutaneous ulcers being the primary gate of invasion. He is of opinion that these are local secondaries or lymphatic metastases, just as the bubo is the bacterial metastasis. Rare cases with lymphangitis ascendens as a primary affection were admittedly observed. The primary gland swelling of the skin seems to be the initial point.

The channels of invasion are evidently in the order of their importance—the skin even when no obvious lesion exists, the tonsils, and the lungs. Intestinal infection cannot be supported by any inference. Of all the cases examined only one had secondary ulceration of the bowel.

Bacteræmia is a common attribute of the initial stage of the disease, but is not constant enough to found

a conclusive opinion on; indeed many severe forms of bacteræmia recover. The rapid forms of death are due to cardiac failure. The rapid small pulse with little fever is a bad omen. This condition of the heart often occurs when the disease is well advanced, and usually proves fatal. A common associate in the symptoms is a cerebral disturbance resembling that observed in tuberculous meningitis, which Müller interprets as evidence of absorption of bacillary products of a toxic nature. The complications are pus formations and open buboes.

As to the epidemiology of the disease, it may be mentioned that none of the medical staff or nurses of Arthur Road Hospital have at any time fallen victims to the disease, even when they have had open wounds on their person; thus wound infection cannot be accepted as a channel of admission. The most successful treatment is extirpation of the primary gland swellings.

The pathological part, based on 48 post-mortems, is given by Albrecht and Ghon. They divide the cases into (1) primary buboes in the neck, axilla, and inguinal region; (2) where no positive proof of primary bubo exists unless general swelling of all the glands be reckoned as such; (3) and lastly, two cases of secondary infection terminating in marasmus. Both authors agree in the characteristic morbid appearance of enormous hæmorrhagic infiltration of the lymphatic glands which goes on to necrosis and formation of a creamy pus. Secondaries may be traced along the lymphatic vessels to fresh inflammatory hæmorrhages. In the effused blood and primary affected glands large members of the plague bacilli can be found also in the perivascular spaces, more particularly the venous terminals in the sub-endothelial hæmorrhages which seems to be the invading point of the bacilli in entering the circulation. The spleen is greatly enlarged, giving a peculiar deep red on section, and is of firm consistence.

The pneumonia is lobular with confluent centres. The section is speckled red and yellow, but not granular, while multiple metastatic centres are strewn over the surface. As the disease advances the bacilli increase in the blood till bacteræmia is produced frequently, producing different degrees of ecchymosis in the skin and mucous membrane. In a few cases pyæmia may be the immediate cause of death.

The histological and bacterial examination point conclusively to the lymphatic tissue as the principal nutrient of the bacilli, which make their way into the surrounding tissues and along the various vessels. Their product acts as a toxic to the cells, and finally produces necrosis. This poisonous product acts violently on the cerebral tissues and heart.

Albrecht and Ghon, in summarising their results, are inclined to believe the mode of infection to be through a lacerated or abraded surface of the skin. The germ having gained admission incubates for from four to seven days, and this is speedily followed by primary bubo or swelling of some of the glands. This view is supported by the absence of lymphangitis, which is a rare exception in the disease. Experiments on animals are followed by similar results.

Pöck's part of the report deals with the experiments of injection and transmission. The secondary disease of the throat is not due to poison from the lung *via* the sputa, but rather to the general glandular enlargement

The Operating Theatres.

CANCER HOSPITAL, BROMPTON.

ABDOMINAL HYSTERECTOMY FOR CHRONIC FIBROID THICKENING OF THE UTERUS.—Mr. CHAS. RYALL operated on a married woman, æt. 35, who had been suffering for many years from menorrhagia, dysmenorrhœa, and frequent attacks of abdominal pain. She had been curetted several times without any relief. On examination, the uterus was found to be retroflexed and fixed in Douglas's pouch, and the fundus enlarged to about the size of a cricket-ball. It felt as if the site of a small fibroid tumour. It was therefore decided to perform hysterectomy because no relief had been afforded by former treatment, and the abdominal route was selected for operation owing to the apparent fixation of the uterus in the pouch of Douglas, and the more ready means of dealing with adhesions through an abdominal incision. After the patient had been anæsthetised the abdomen was opened through a median incision, and the patient was placed in the Trendelenburg position. It was found that the fundus uteri was adherent to the peritoneum of Douglas's pouch and to the sigmoid; the adhesions were carefully broken down and the uterus drawn out through the abdominal wound; on examination no tumour could be found, but the uterus was greatly enlarged, its walls were hard and thickened, and beneath its peritoneal investment one could distinctly recognise great excess of fibrous tissue. The cervix appeared normal. Hysterectomy was then performed in the usual way, a small cervical stump being left behind, and the pelvic floor was completed by suturing together flaps of peritoneum removed from the anterior and posterior surfaces of the uterus. The abdomen was then closed in three layers. Mr. Ryall said that the case was of interest because of the nature of the trouble. Here was a patient suffering from chronic symptoms which could not be relieved by less severe means; drugs and curetting he considered to be absolutely of no use in these cases of chronic fibroid thickening of the uterus; the disease was a fairly common one, though the literature on the subject was very limited; it was essentially inflammatory in origin, and might occur as a sequela of septic endometritis, though it has been known to take place in virgins where such a cause could not be discovered. The pathology of the affection consisted in the thickening of the uterine walls by fibrous tissue, and in the disappearance in part of muscle fibre; there was always associated hyperplasia of the endometrium. The result is that the uterus loses its tone, its cavity becomes enlarged, and the organ itself is liable to displacement, owing to its increased weight, as well as to its loss of tone. With regard to the formation of flaps in the operation, he pointed out that the anterior flap was dissected from the uterus from above downwards, and, after the cervix had been cut across, the posterior flap was dissected from below upwards, as he found that this latter procedure was a great saving of time and trouble. In the ordinary method of dissecting the posterior flap from above downwards he always had found a difficulty in separating the peritoneum from the uterus, which difficulty is obviated by employing the method he had utilised. He considered the closure of the abdomen in three layers rendered the

patient less liable to hernia, and common-sense, he thought, dictates that in the closure of any wound, it is more anatomically correct to approximate similar divided structures. He said he thought it a good plan to get the patient's bowels to act in twenty-four hours' time after the operation.

It is satisfactory to state that the patient made an uninterrupted recovery, and was allowed out of bed three weeks after operation.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR A SERIES OF INSERTIONS:—Whole Page, thirteen insertions (weekly, fortnightly, or monthly), at £3 10s. 6d.: twenty-six insertions (weekly or fortnightly) at £3 3s. 0d.: fifty-two insertions (weekly) at £3 each. Half Page, thirteen insertions at 35s.: twenty-six at 32s.: fifty-two insertions at 30s. each. Quarter-page, thirteen insertions at 18s.: twenty-six insertions at 16s.: fifty-two insertions at 15s. each. One-eighth page thirteen insertions at 9s.: twenty-six insertions at 8s.: fifty-two insertions at 7s. 6d.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d.: Half Page £3 10s. 0d.: Quarter Page, £1 5s.: One-eighth, 12s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books &c.—Seven lines or under, 4s. per insertion; 6d. per line beyond.

Letters in this Department should be addressed to the Publishers.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 27, 1899.

PUBLIC ANALYSIS AT SECOND HAND.

THE responsibilities attached to the post of public analyst are heavy and onerous. Not only do they demand the exercise of the highest technical skill, but they involve the giving of evidence which may determine grave issues, not only affecting property but also the liberty and even the lives of individual citizens. To take one further detail, their labours are essential to the maintenance of the purity of the food of the people, an object of prime importance to the welfare of the community. Nor is there any need to insist upon the personal nature of the work of the public analyst. As a rule, he is chosen on account of his high scientific qualifications, and the condition is implied that evidence given by him in court is the result of his own observations and investigations. It is not a little startling, then, to learn that it is the custom of at least one well-known Public Analyst to hand over his laboratory work to a subordinate. This information is gathered from the report of the prosecution last week of an ice-cream vendor by the St. Olave's District Board of Works in South London. A sample of the stuff purchased from one of defendant's barrows had been sent to Dr. Stevenson, the Board's Analyst, and a certificate had been received

signed by that gentleman stating that the ice-cream contained twenty millions of microbe organisms per one cubic centimetre. Dr. Stevenson attended as a witness, and in the course of cross-examination admitted that the analysis had not been made by him personally, but by his bacteriological assistant. This admission was naturally seized upon by counsel for the defence, who urged that according to the Act the public analyst must do the work himself. The magistrate agreed with that contention and dismissed the summons. He observed that he would have accepted the certificate without suspicion as the result of an analysis made by Dr. Stevenson himself, but for that gentleman's admission. The state of affairs thus disclosed cannot be regarded as anything other than serious. Here we have a highly-paid expert coming into court and signing certificates of analysis which clearly misled the magistrate as to the authenticity and weight of the special evidence furnished by the analysis. Well may one ask how many of our fellow citizens are being convicted upon the analysis made by an unknown and irresponsible assistant. It is obviously the fact that it is impossible for many public analysts to analyse every sample themselves. The obvious answer is that a man holding such a post should not undertake more work than he is able to perform. It may interest our readers to consider some of the facts concerning these appointments as disclosed in the pages of the "Medical Directory" under the heading of Metropolitan Vestries. We find that Dr. Stevenson holds the post of Public Analyst to the counties of Surrey and Bedford, and to the parishes of St. Leonards, Shoreditch, and St. Pancras, and to the Board of St. Olave's, Southwark. When we recall the fact that the same gentleman is Official Analyst to the Home Office, lecturer at Guy's Hospital, and examiner both at Cambridge and London, there is little wonder at his inability to undertake complicated bacteriological examinations. This question of plural public health appointments in London, and to a less extent in other parts of the United Kingdom, has grown to be little short of a scandal. Pursuing our inquiries, we find Dr. W. R. Smith acts as Public Analyst for Woolwich and for Lee. He is also medical officer of the large district of Woolwich, holds a Professorship at King's College, and is medical officer of the School Board. To ask a man holding so many offices in places miles apart to conduct minute chemical and biological analyses on the result of which may hang issues of vital individual and general importance is to run the risk of disaster, for human capabilities are finite. Dr. Muter and Mr. Stokes hold the posts of Public Analyst to four Vestries; Mr. Colwell and Mr. Cassell to three and many others to two. In some cases the Medical Officer of Health holds the post, but that we regard as inadvisable, for the sanitary duties of the smallest parish in London, if properly discharged, are far more than enough to occupy the full time and energies of any single man. The fact that many of the Vestries want as

little as possible done in the way of efficient work should not be permitted to stop the way. Plurality has been the bane of sanitary administration in the metropolis. In the particular department with which the analysts are concerned it has no doubt done much towards encouraging the adulteration that pervades the national food supply to a well-nigh incredible extent. It is to be hoped that in the readjustment of parochial affairs which will take place shortly under Mr. Balfour's new Act that the undesirability of plural appointments will not be lost sight of by those who are entrusted with the responsible duty of electing public officers.

THE VACCINATION QUESTION.

"Time hath my lord a Wallet at his back wherein he puts alms for oblivion; a great sized monster of ingratitude."

It is well for us at this near end of a century, when a balance of accounts must interest many, to be careful how we allow alms to be put into Time's Wallet. There seems to be a singular desire on the part of some to do this in the matter of vaccination. They apparently wish that Jenner had never lived, and they would like to wipe his name out of their list of creditors. How is it that this idea has arisen? Is there any justification for it? After all, what are really the questions we have to consider when dealing with vaccination from all points of view. Is vaccination of value in preventing the malign influence of a terrible malady or not? In asking this question we desire it to be understood that we ourselves entertain no shadow of doubt that the answer must be emphatically in the affirmative, and we put the question simply to formulate the opposite opinion. Knowledge of every kind can be used for good or bad. There are some who fully admit the value of vaccination, but do not admit that the liberty of the individual should be interfered with in any such way as the legal enforcement of vaccination inflicts on them. The right of the individual to deal as he pleases with his child is in the opinion of some not to be questioned. The relation of the individual to the State has from earliest times been one of greatest interest; and how far the State may interfere with the parent in his relation to his child has been a subject of much contention. If a parent thinks that he ought to be left free to do as he pleases with his child, he may make up his mind to choose some other country than this, for we shall certainly not agree to let parents do what they please, if what they do, in public opinion, is injurious to the child. If a man had to deal with a question of purely personal and individual interest it would be a very different matter, though the question might arise whether we should care to let those live among us who might become dangerous from being, like an explosive machine, liable to damage others as well as themselves. The question whether vaccination will prevent small-pox or not prevent it cannot be raised by any but those who are wilfully ignorant or maliciously inclined. What Jenner proved years ago time has

confirmed, and to no one in the profession is the world more indebted than to Edward Jenner. Why then are there many good and sensible men who would leave a parent to do as he likes in having his children vaccinated or not? If we go into this question carefully we find that the reason given is that the advantages of security against small-pox are counterbalanced by the risks of injury that may be done by vaccination. What are those risks which seem to alarm some people so greatly? Is there any sense in the view that it is better to run the risks of small-pox than the risks of vaccination? This is a question which cannot be decided by any but the members of the medical profession, and if they are not able to decide it we cannot be surprised at any view being taken of it by others. There is undoubted evidence that if vaccination is not properly performed it is possible that under exceptional circumstances ill results may arise, and if it can be shown that the profession has neglected to protect the public against such risks, or at least to explain them clearly, the consequences must be unpleasant. The use of calf lymph in preference to human lymph is an acknowledgment of this possibility, and of the disquietude of the popular mind on the subject. The disease that has been most feared is syphilis, and there has been a great change in opinion since Jenner's time on this particular point. It is well to give John Hunter credit for the work he did; at the same time it is unwise to claim for him more than he deserved. Those who are constantly harping on the memories of the past are not the men who contribute to progress. They are generally men who have done nothing themselves, and are jealous of those contemporaries who have done something. Now, there is not the least doubt but that a healthy child may possibly be infected with syphilis if vaccinated with lymph taken from a syphilitic one. It is of no use to deny this, for to do so is practically to deny the truth. It is better honestly to admit the validity of the charge that is thus made against it, and to do the best to make some compensation for what was done, not in malice, but in ignorance. But having disposed of the possibility of syphilitic infection by vaccination, the question that would at once be asked is whether there are not other maladies that may be similarly communicated. If the lymph that is used is not healthy lymph, it must be allowed that some ill consequences may follow its inoculation. The simple fact is that if lymph is taken later than is proper, or if, in preserving it on points or in tubes, proper care is not observed, there are undoubtedly risks of infection with a poison which may seriously injure a healthy child. While admitting the possibility of transmission of inoculable diseases by careless vaccination we recognise that the proved cases of such transmission have been so extremely rare as compared with the enormous number of vaccinations that we may claim that the exception proves the rule that the operation is of infinite value, and entails little risk. Nevertheless, we are

bound to satisfy the apprehensions of parents until we are able to assume them that there is no risk whatever. The great principles of antiseptic surgery depend on the prevention of infection from the use of instruments in surgical operations which might possibly convey a poison. If it can be shown that those principles can be applied, and they most certainly ought to apply, to vaccination; and that if they are, the fears of many may be allayed, it is probable that the real cause of opposition to vaccination will be removed; that cause being the fact that some have suffered from neglect of the precautions which would have prevented the injuries apparently due to it. Even such an easy and commonly neglected matter as the treatment of the vaccine pustule in its various stages when an open wound is liable to infection, requires attention, and many of the troubles that have followed vaccination could be traced to their neglect. We might criticise the Royal Commission and the work it did. It hardly struck one as having been constituted on a strictly impartial basis, for it was distinctly composed of some who held strong views on one side, and some on the opposite side; and the witnesses were treated as though they always appeared for the prosecution or the defence. This is a subject, however, which we can defer for future consideration. At present we are more interested in showing what is due to Edward Jenner when balancing the accounts of the nineteenth century and in not letting Time's wallet get alms it has no right to.

THE TREATMENT OF GLAUCOMA BY RESECTION OF THE CERVICAL SYMPATHETIC.

THE etiology of glaucoma still remains a problem which ophthalmologists have failed to solve. It is true that we are a little nearer that solution than was the case when Graefe alighted upon that brilliant method of treatment which has since saved so many eyes from becoming blind from glaucomatous tension. But the fact nevertheless remains that beyond the knowledge that the glaucomatous process is mainly associated with increased intra-ocular tension, nothing very definite is known concerning this most serious and mysterious malady. However, it is not from any lack of investigation that this present unsatisfactory state of affairs exists. Ocular pathologists and others have from time to time carried out painstaking researches with a view to throwing light upon the mystery. Various theories have been evolved tending to show the ocular conditions present in, and the causes which underly, an attack of glaucoma. But it cannot be said that any of these theories are satisfactory, or that they supply the deficiency in our knowledge in regard thereto. On the other hand it might be considered that, after all, whatever the true etiology of the disease may be, the bright feature concerning it is the success of its treatment by iridectomy. The brilliant results of this treatment are likely to be maintained as long as glaucoma remains a disease to be treated. But here the "rift within

the cloud" is that these results can only be said to apply to the acute cases. In chronic glaucoma iridectomy has often little, if any, restraining influence upon the disease. Herein, then, becomes apparent the significance of the insufficiency of our knowledge regarding its etiology, for while an early iridectomy for acute glaucoma may permanently restore the vision of an eye, in the chronic cases the glaucomatous processes may, nevertheless, progress, with scarcely any perceptible increase in the tension. Thus, in the latter cases, it is quite possible that an iridectomy, if performed, might be productive of more harm than good, and in many of these it is an open question whether the operation should be performed at all. In view, then, of these facts it is not surprising that investigators should have gone further afield than the ocular region in order to throw light upon the etiology of glaucoma, and in this connection attention has been drawn to the influence of the cervical sympathetic upon the disease. The pioneer in this field of inquiry has been Jonnesco, of Bucharest, who has now upon eight occasions, resected the cervical sympathetic for the relief of glaucoma. The cases upon which the procedure was practised varied greatly in the degree of their intensity, but in all the results, as claimed by the operator, were most gratifying. For example, there were noticed immediate and lasting reduction of the tension—presumably where this existed—marked contraction of the pupil, cessation of the ciliary pain, and of relapses, noteworthy and lasting improvement of the vision in those cases in which atrophy of the optic nerve had not previously ensued. Thus it can be readily gathered from these results that the operation in its beneficial effects eclipsed those which would probably have followed the performance of an iridectomy, and the good influence thus brought about is attributed by Jonnesco to the physiological effect upon the eye caused by the removal of the sympathetic ganglia. The disturbance of the nutrition of the eye upon which glaucoma presumably depends is further regarded by Jonnesco as a nerve change due to an irritation of encephalic or medullary centres from which fibres pass to the sympathetic. By removal, then, of the superior cervical ganglion, the pathway of evil influences, by which disturbing nutritional changes can ensue in the organ of vision is thus cut off. However, it is not needful here to discuss further the results which Jonnesco claims to have obtained. It is natural that he should be enthusiastic in regard to his novel procedure, and it is natural also that he should have evolved theories in support of his ingenious contentions. But, obviously, before his treatment can come to be regarded as sound in principle, it will have to be put many times to the test by independent observers. Meanwhile, from the point of view of the patient, it may be said that an iridectomy is a trifling mutilation in comparison with the procedure required for the removal of the superior cervical ganglion, and moreover, if the

latter operation were to supplant the former in the treatment of glaucoma, the question would come to be raised whether the general surgeon would not supplant the ophthalmic surgeon in its performance

Notes on Current Topics.

Morbid Self-Assurance.

THE confidence in self which begets what is generally known as self-assurance is a very variable quantity. Often conspicuous by its absence it occasionally presents itself in an extreme degree without warranting the suspicion of mental degeneracy. In this, as in respect of many other mental characteristics, there is what may be termed a normal for each individual, and, however exaggerated, this, the salient feature of a given temperament, may be, it cannot be regarded as a disease. It is, of course, quite otherwise when it develops late in life. A degree of self-assurance which would only excite amusement in an adolescent might justly excite grave apprehensions in a man who has passed the meridian of life, and who has previously been of a modest and even retiring disposition. An unduly inflated idea of the importance of self, if of fortuitous occurrence, is often the first outward and visible manifestation of incipient general paralysis of the insane, a malady which is so often ushered in by the mania of grandeurs. Following up a line of research which he has made peculiarly his own, Dr. Harry Campbell recently brought before his fellow members of the British Medical Association an interesting little monograph on this very subject, wherein he makes it clear how difficult it must always be to draw a line of demarcation between constitutional and morbid self-assurance. Apart from personal idiosyncrasy circumstances of environment exert a powerful influence in developing an exaggerated idea of the importance of self. The privileged position accorded in the old world to the scions of noble families irrespective of their intellectual attainments or moral qualities tends, as a natural and inevitable result, to foster this morbid sense of self-importance. Conscious that merit alone does not explain or justify the deference shown to their persons, they are driven to assume that there must be something inherently superior in their composition, and this belief expresses itself in gesture and behaviour. As we have already pointed out it is difficult, if not impossible, to assign a limit to physiological, as distinguished from pathological, self-assurance, and the physician is fain to look out for corroborative evidence of nervous degeneration before he can safely classify it as a symptom of disease. Nevertheless, in an exaggerated form, self-assurance is unquestionably a deformity, akin to the deformities which impair the symmetry of the body. It is quite possible to be deformed yet healthy, and so, in this respect, it is possible to display this intellectual asymmetry without a sufficient impairment of mentalequilibrium to warrant inclusion

among the insane. When this want of balance affects only one intellectual feature it may pass muster as eccentricity unless, indeed, it takes a form susceptible of causing damage to the community. When this is the case, Society quits the philosophical consideration of such anomalies and promptly sequesters the victim of the anomalous tendency.

Motor Carriages and Country Practice.

RECENT improvements in the mechanism of vehicles propelled by benzoline motors, and their sale at a price which, if still excessive, is yet within reach of the country practitioner, are sure to lead to their taking the place of the grey cob and gig. The advantages, in point of view of convenience and cost of maintenance, of these self-propelled conveyances are obvious, but, on the other hand, they are complicated and somewhat fragile mechanisms. In large towns nothing more than temporary inconvenience is likely to be occasioned by a break-down, since every facility is at hand for carrying out repairs. Such is not the case in the rural districts, and if their use becomes general, a post-graduate course of instruction in the anatomy and physiology of the motor-car will become absolutely necessary. This is never likely to form part of the medical curriculum; but a working knowledge of their mechanism is really indispensable, unless their owners are prepared to put up with unexpected and disconcerting mishaps. Often a little adjustment of a valve or the tightening of a nut is all that is required; but, failing special knowledge, the country boor will be treated to the spectacle of the grey-haired physician engaged in trundling his recalcitrant motor back to the stable. He would be jeered at as were the men in the fable who carried the donkey, and with less reason.

Primary Syphilis in a Leper.

INSTANCES of primary syphilis in a leprosy subject are sufficiently rare to confer interest on all well-authenticated cases of the sort. In a recent number of the *Vratch* Dr. Messaroché records the case of a man, æt. 44, who presented himself in the condylomatous stage of syphilis, but who also presented two small brown patches on the abdomen together with a hard swelling of the left testicle and œdema of the scrotum of some standing. Under the influence of specific treatment the syphilitic symptoms promptly disappeared, but as these subsided a further crop of similar brown patches made their appearance on the skin of the abdomen and these patches were anæsthetic. The subsequent history of this patient confirmed the double diagnosis and left no doubt in the minds of observers that the case was one of syphilis in a leper. The points to note are that in this case the leprosy taint exerted no modifying action either on the syphilitic infection, which ran its usual course, or upon the action of the anti-syphilitic remedies. It was noted that the administration of iodide of potassium appeared to favour the spread of the leprosy cutaneous manifestations.

The Mercenary Doctor.

AN inquest was held a few days since at Scarborough on the body of a child who had died without medical treatment owing to the refusal of a local practitioner to attend when summoned late at night. Several members of the jury waxed very wrath and passed some very severe strictures on the doctor's "heartless conduct" in thus refusing to attend, merely (!) because he was told that no fee was to be had. As the medical practitioner in question happened to be the police surgeon it would perhaps have been policy either not to answer the bell or to have responded to the summons—but the virtuous indignation of the jurymen is certainly out of place and one wonders what their attitude would be if roused in the small hours to furnish bread or brandy to a sick or starving person, especially if they were duly warned that the applicant could not pay. We are strongly of opinion that it is the duty of the public to provide medical attendance in urgent cases at all hours of the day and night, irrespective of the means of the sufferers, but if public opinion coincides with ours, it is only necessary to follow the example of most foreign municipalities in organising a night service of medical men who are willing to undertake this class of work at stated fees payable out of the city funds. To pretend to impose this duty on private practitioners without fee or reward is unjust and even preposterous. Gratuitous medical attendance at hospitals and dispensaries has led the public to suppose that they have a vested and inalienable right to prompt attention, even when they are not prepared to pay for it, and this pauperisation is the natural outcome of a vicious system, against which the profession have at last begun to kick.

The Prolongation of Life in Incurable Cases.

FROM time to time we are asked to discuss the ethical question whether it is right for the medical man to avail himself of the means which science places at his disposal to prolong life in cases which are of their nature hopeless. Every practitioner must have asked himself this question when confronted with the spectacle of a patient whose unhappy existence he is perhaps reluctantly the means of prolonging. To this question, however, there can be but one answer, that the duty of [the practitioner is to alleviate suffering and to prolong life under all circumstances. To admit any exception to this rule would be to introduce a dangerous element into medical conduct, for by so doing the medical man would virtually be assuming the right to decide when life should come to an end, a responsibility which few, we hope none, would knowingly accept. Moreover, medical science is not infallible, and it is not within our power in a given case to be absolutely sure that the condition is as hopeless as it seems. We are constantly being reminded of instances of recovery after the sufferers have been "given up" by the Faculty, and deceptions in the matter of prognosis are sufficiently frequent to make one hesitate to state dogmatically that

death is imminent and inevitable. Lastly the patient has a right to be heard, and although it is by no means uncommon for people to declare that they would welcome release from suffering, in the majority of cases life with all its pains is preferred to the grim and uncertain future. Again, if the principle of non-intervention were conceded in cases of incurable disease it would logically apply with equal force to the weakly and the infirm among the young, a conclusion from which humanity recoils with a shudder.

Lunacy in Scotland.

It is a significant fact that the steady increase in the proportion of lunatics which, south of the Tweed, is ascribed to life at high pressure, obtains also in the country north of that boundary where one might have supposed that the conditions of existence were less exacting. Recent returns show that in Scotland, during the years 1859-63, the average number of patients was 5,129, while for the last statistical year the number had risen to 12,482, entailing an expenditure three times in excess of that for the earlier period. No doubt a share of this startling difference may be put down to the more ample accommodation provided for a class of lunatics who were formerly allowed to wander at large, but this cannot explain the extraordinary increase manifested during the last two or three years, 487 new cases in 1898 as compared with an average of 245 for the five preceding years. As might be expected, the incidence of lunacy falls principally upon the inhabitants of towns and cities, the rural returns remaining almost stationary. It is not the half-starved proprietors of three acres and a cow who

"Go mad and beat their wives,
And, after shocking lives,
Plunge razors and carving knives
Into their gizzards."

but the anxious busy tradesman, the ruined stockbroker, the harassed doctor or the disappointed barrister. Agricultural pursuits involving a laborious life in the open air, comparatively free from intellectual preoccupation and professional stress, are eminently favourable to mentalequilibrium, while, on the other hand, the abuse of alcohol and tobacco and the manifold opportunities for nervous excitation which characterise city life, tell heavily on those whose nervous organisation is inherently deficient in stamina.

The Cure of Inebriety by Restraint.

THE report of the Dalrymple Home at Rickmansworth, near London, presents some very interesting figures. Since its establishment it has treated 518 patients, whose average age was 36.3 years. Of these 35 were medical men, and the influence of idleness and opulence in encouraging intemperance may be discerned in the fact that 124 were men of property with nothing to do, and 56 were merchants. The result of the treatment is, however, the most important consideration, and we derive from the report that, of the 518 cases, 169 did well after their liberation, and 27 were improved,

but of 97 nothing had been heard, and it was known that 181 had relapsed into inebriety. This would be a disappointing result did we not realise that, by the law under which such institutions are administered, the term of restraint was voluntary, and usually was totally insufficient to admit of complete recovery, being on an average only about six months. The inebriate was seldom willing, even in his most penitent mood, to sign himself in for a longer period, and the expense of his maintenance in the institution was so considerable that his friends were not willing either. Everyone experienced in this form of disease knows that a permanent cure cannot be looked for unless the patient can be isolated from alcohol for at least a year, and the principle of restraint is therefore not discredited by the relapse of many after half that period.

Alcohol Dressings in Psoriasis.

THE most recent method of treating psoriasis is that suggested by Dr. H. Lau, to whom it occurred that spirit dressings might be expected to have a beneficial influence upon the œdema and congestion of the papillæ which characterises this affection, and the experiments which he carried out appear to have fulfilled his expectations. His method consists in applying every evening to the affected areas compresses of absorbent cotton steeped in rectified spirit containing 2 per cent. of salicylic acid. The compresses are covered with a layer of protective and left on all night. The next morning the patches are scrubbed clean by the aid of soap and a sterilised nail brush. Should the skin become chapped or excoriated he interrupts the treatment for a day or two and applies lanoline ointment. He asserts that the results are, at least, as good as those obtained by tar, pyrogallol, chrysarobine, &c., and the spirit dressing has the advantage of being cleanly and easy of application.

An Infectious Diseases Hospital for Dublin.

THE conference of the Sanitary Boards of the Dublin district held last week, under the auspices of the Public Health Committee of the Corporation, inspires us with the hope that at length something practical may be done to avert the dangers to the citizen which the present slipshod system of sanitation involves. It is scarcely necessary to spend time in enunciating the necessity for enlarged and more effective provision for infectious diseases within the district. The existing accommodation for such cases consists practically of one special hospital of 120 beds (of which about eighty are usually occupied)—one branch of a general hospital containing 120 beds, and such minor accommodation as can be offered by small wards in two or three general hospitals. Such accommodation for infective diseases is, doubtless, enough for every day use, but insufficient for occasional exacerbations of disease which are quite frequent in all large cities, and altogether ridiculous as a provision when a serious epidemic occurs. When such a catastrophe has hereto-

fore arisen the sanitary authorities have sought to meet it by setting up shanties of corrugated iron and wood which temporarily protected the fever patients from the weather, and this they would have to do if a grave epidemic broke out to-morrow. It goes without saying, therefore, that increased permanent accommodation for infective cases must be provided, and Sir Charles Cameron suggests two alternative methods, the immediate object of which is to provide funds for the erection of one, or perhaps two, hospitals for infective disease. The first is that all the sanitary authorities in the vicinity of the city shall combine to form a Hospital Board which shall obtain, by provisional order, the requisite power to tax the whole area for the purpose, and the second is that the Corporation alone should undertake the cost of building and maintenance, receiving from the extra-corporate sanitary authorities a contribution, per week, for each fever patient whom they send into the hospital. It may be stated at once that the first of these propositions is the best, but that the second is much the most easily carried out, because the first would involve an application for a provisional order, and would thus involve the letting out of a thousand oppositions. Among the opponents would be (1) the hospitals which would see their function, *pro tanto*, abolished and their students forced to go elsewhere for the study of infective diseases; (2) the denizens of the localities where it might be proposed to erect the new hospitals would certainly avail themselves of every legal formality to thrust off the incubus of the infective hospital on their neighbour; (3) the Dublin ratepayers, who, having recently had to swallow the nauseous dose of £91,000 for providing villas for artisans, are firmly determined to block every proposal for large expenditure of money on any scheme which is not absolutely indispensable; and (4) the boards of guardians, who, probably, would resist any scheme which would merge their control and influence in a central hospital board, while compelling them to contribute to the expense. Notwithstanding these hindrances we trust that the proposal for a provisional Order and a combined hospital board will be adhered to as being the only stable alternative. That, in a city like Dublin, it should be necessary, as Sir Charles Cameron expresses it, to "hawk about" an infected patient, failing to find accommodation in hospital, is an intolerable barbarianism, and, if the provision of sufficient accommodation can be obtained without architects' vagaries and builders' jobs, it ought to be done without further parley.

The Patient Stomach.

THE rush of modern civilisation leaves little time for the average man to think of anything outside the immediate tether of his own absorbing pursuits. He is content to eat, drink, sleep, and take his pleasures as they come, without encroaching upon the period of his scant recreations by such solid labour as that involved in consecutive thinking. In this way eating and drinking are regarded much as breathing, or the

complex nervous and muscular acts that take place in walking or talking; all are accepted as matters of course. Indeed, it is just this easy way of treating vital functions that only too often leads to their abuse. Let the reader pause for a few moments and think how he treats, and has been in the habit of treating, his own patient stomach. Does he begin the day with a heavy breakfast, including several cups of strong tea? Does he take a meat luncheon, with wine or other alcoholic drink? Does he indulge in afternoon tea and wind up with a dinner of half a dozen courses, tempered with more alcohol? If a man does he distributes odd alcoholic drinks over the whole day's programme? If of either sex, is tobacco included in the daily trials of the stomach? A steady course of public dinners would, in time, ruin the digestion of a rhinoceros or an ostrich. The three square meals a day of the average country house quickly upset the digestion of the visitor, who is used to think highly and live plainly. Indeed, no great intellectual activity can be permanently associated with gluttony. The amount of abuse the modern civilised stomach can withstand is an eternal monument to the perfecting powers of the evolutionary survival of the fittest.

A "Certified" Midwife and "Stillbirth."

LAST week a coroner's inquiry at Westminster upon the infant child of a single woman revealed a state of affairs that deserves more than passing comment. It appears that the "certified" midwife took women into her house for confinement. The child was stillborn, but no attempt was made at artificial respiration. The medical evidence showed that the child was prematurely born, and the lungs were not inflated. These facts alone suggest a serious state of matters, the investigation of which may be left in the hands of the police. There is a further serious element in the case, however, namely, this midwife was in the employ of the Western Dispensary. It is obvious that no public medical charity should employ a midwife except she be of approved skill and of the highest character. Most people will form their own conclusions as to how far those conditions were fulfilled by this particular woman. Does no responsibility rest with the honorary medical staff of this institution? We find that Dr. Allchin is honorary consulting physician, and Mr. Thomas Bond consulting surgeon, while Dr. J. B. Potter is the honorary consulting accoucheur. Surely these gentlemen cannot willingly be associated with such proceedings as those that formed the subject of the above-mentioned pertinent inquest. It is, of course, a well-recognised fact that honorary medical staffs absolve themselves from the acts of the committee of management. Sooner or later, however, a day of reckoning must come between the medical charities, so called, and the main mass of general practitioners, and those consultants who are wise will disassociate themselves from institutions in the management of which medical men have no voice.

Sanitary Removal by Force.

LAST week an incident occurred in South London which is fortunately rare in the annals of preventive medicine. Diphtheria has recently raged in a certain quarter of Southwark, and a boy of ten was certified to be suffering from the disease. The family in the house consisted of father, mother, and four children, the latter aged respectively 17, 15, 13, and 10 years. The mother violently resisted the removal of the child, and tore up the certificate. Thereupon an application was made for a compulsory removal order to a hospital to Mr. Slade, who granted the order. The English Act states very definitely that proof must be given that the patient is without proper "lodging or accommodation" before an order for compulsory removal be made. It is to be presumed that an experienced magistrate like Mr. Slade demanded full and satisfactory evidence as to the patient's surroundings before he took the extreme steps of signing such an order. Anxiety to avoid running counter to the prejudices of the people was evidently a main principle in the mind of the framer of the Act. We note, however, with no little wonder, that the application in this highly important matter was made by a sanitary inspector, and it is to us perfectly incomprehensible how a London magistrate should listen to anyone but the responsible Medical Officer of Health of the Parish. If this outraged mother is of the ordinary British bull-dog breed, the Vestry, whose zealous sanitary inspector has procured this ill-starred magisterial authority, may expect further legal complications in other and higher courts.

The Outcome of Midwives' Registration.

THE State Board of Health of Illinois affords us an object lesson which enables us to anticipate the probable working of Midwife Registration if it should be introduced into this country. The State Board, finding that the registered midwives had gone in wholesale for practice as physicians and surgeons, has found it necessary to issue to each of them a peremptory circular which warns them that "midwives are forbidden by the law to call or advertise themselves as physicians or doctors, and prohibited from using any drug or medicine and from attending other than cases of labour," and it threatens that a "violation" of the regulations will subject (you) to a prosecution and will be deemed a "sufficient cause for revoking (your) certificate." Inasmuch as the peremptory infliction of such a penalty would be found extremely difficult in Great Britain, it stands to reason that we should be the more cautious in giving midwives an inch, being convinced that they would certainly take the proverbial ell.

Dermatology for the General Practitioner.

LIKE all special branches of medical science dermatology is more or less buried beneath the mass of its own learning. The accumulation of facts has gone on at a great pace, while the generalisations in causation and treatment have in many cases yet to

be made. In the case of ringworm, for instance, immense strides have been made in the differentiation of the fungus, but the cure of the disease has not been advanced one jot. If the general practitioner desires to refer to any special condition, he finds himself confronted by many large books of reference, but he may as well look for a needle in a haystack as attempt to identify any condition with the name of which he is not already acquainted. For many conditions there are half a dozen names, and the medical leaders in each town insist upon opposite theories. Yet there are some who advocate adding the diseases of the skin to the already bewildering curriculum of the medical student. As yet no satisfactory classification of the subject has ever been devised, which is another way of saying that the fulness of knowledge is not yet at hand. A short, terse, plainly written book on dermatology, dealing only with the commoner conditions likely to be met with in every-day practice, would be likely to fill a gap in the shelves of the general practitioner.

Hospital Reform Association.

THE forthcoming Conference under the auspices of the above body is likely to prove of an interesting and instructive character. We think the Association has been well advised in asking gentlemen to take up specific points in their papers rather than to deal with the whole question of Hospital Reform. There can be no doubt that more light is wanted on the subject of inquiry into the circumstances of patients. Then again the subject of patients' payments is one that requires to be dealt with in a vigorous way. For our own part, we look upon the out-patient payment system as likely to increase rather than diminish the amount of abuse already rampant in our out-patient departments. We should like to hear the experience of the staff of the London Hospital on this particular point—that is to say, if they have not altogether surrendered their consciences and beliefs to the lay philanthropists who know little and care less about the interests of general practitioners. We are glad to hear that representatives of provincial charity organisation societies have promised to attend the conference.

Sanitary "Trop de Zele."

WE have repeatedly remonstrated with sanitary authorities who seem to have striven to bring the Adulteration Acts into disrepute by instituting prosecutions on the most frivolous grounds. No doubt it is a technical infraction of the law that soda-water should not contain the ultimate atom of soda, and that a dispenser should add two grains of iodide of potassium more than the prescription indicated, but we should think that a fine of one penny and no costs would "fit the crime." We make this observation in view of the decision of Mr. Rose, the magistrate at the West London Police-court, who dismissed the last-mentioned prosecution because, as he said, he did not think that the Act of Parliament was made to cover such homœopathic infringements.

Gelatine Injection for the Cure of Aneurysm.

THE recent announcement by M. Lancereaux that aneurysm, even of the aorta, may be consolidated by the hypodermic injection of gelatine, has been confirmed by Professor Stoicesco, of Bucharest, in the *Journal de Medecine Interne*. If the statements of these physicians are to be believed—and they are entitled to every confidence—we are about to enter on a new phase of the treatment of an affection hitherto regarded as almost hopeless.

M. Scheurer-Kestner.

THIS gentleman, who died last week, was best known to the public as an apostle of the Dreyfus cult, but he was also a distinguished chemist. During the sixties he was an active member of the Paris Chemical Society, and published a learned work on the "Elementary Principles of the Chemical Theory of Types Applied to Organic Compounds," besides many other paper on chemical questions. He afterwards became the manager of an important chemical factory.

The Serum Industry.

THE development of the treatment of various diseases by inoculation with serums has been followed by a severe run on the Pasteur Institute, which has been engaged for a considerable time in preparing them. The anti-rabic serum is, of course, of old standing, but more recently a demand has arisen for anti-tetanic, anti-diphtheritic, and, lastly, anti-plague serums. Most of the latter has been sent to Portugal and its vicinity, but the directors of the Institute assure us that they have still an abundant supply of all these prophylactics on hand.

PERSONAL.

PROFESSOR SIMS WOODHEAD, M.D., F.R.S., will deliver the Introductory Address at the Royal Veterinary College, London, on Monday next, at 12 o'clock.

MR. JAMES PRIOR, M.R.C.S., who has occupied the post of house-surgeon to the Dewsbury and District Infirmary for the last four years, has, on resigning the post, been presented with a clock in oak case in recognition of his past services.

DR. M. A. ADAMS, who did such good service in the recent typhoid epidemic at Maidstone, and who has held the position of Medical Officer of Health to the borough for upwards of twenty years, has now resigned the appointment to the great regret of the Council.

DR. E. SYMES THOMPSON, M.D., F.R.C.P., Gresham Professor of Medicine, will commence a course of four lectures at the Gresham College, Basinghall Street, on Tuesday next, at 6 o'clock, on "Earth, Air, Water and Insects in Relation to Disease." These "Foundation" lectures are free to the public, and will be continued on Wednesday, Friday, and Saturday at the same hour.

DR. REGINALD FARRAR, M.A., M.D. Oxon, D.P.H. Cantab, who has been selected to go on the Plague Commission in India, is a son of the eminent author and preacher, Dean Farrar, of Canterbury Cathedral. Dr. Farrar is a former House Surgeon of St Bartholomew's Hospital, London, and has recently filled the post of Surgeon to the Rutland and Stamford General Infirmary, and to the Post Office.

At the election last week of a bacteriologist for the City of Glasgow, a good many personalities were introduced into the contest. Dr. Erskine, in urging the claims of his candidate, volunteered the statement that the City Council had not much respect for the profession. Another Councillor who knew what "doctors' certificates" were worth, would not give a snap for them. Eventually Dr. Robert Buchanan, of Anderson's College, was elected by 29 votes to 27 of his opponent.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

EDINBURGH INSTITUTE OF PUBLIC HEALTH.—The plans have now been passed for this new institution in connection with Edinburgh University, the cost of the erection of which will be entirely defrayed by Sir John Usher, Bart., of Norton. The building will consist of three stories, consisting of a centre block and two wings. The ground floor will be occupied on the east wing by a large museum and the janitor's premises. In the centre there will be research rooms, a gas analysing room, and lavatories, and in the western wing there will be workrooms and cellars. The first floor would consist in the east wing and centre, of chemical laboratory, optical room, water analysing room, research rooms, and reading-room; while the west wing of this and the top flat would be occupied by a very extensive lecture theatre, capable of holding a large number of students. Besides the theatre, the third storey will contain a bacteriological laboratory, observation and research rooms, and adjuncts to the professor's laboratory.

GLASGOW UNIVERSITY LORD RECTORSHIP.—It has been officially stated that owing to certain considerations affecting his position in the diplomatic service, Lord Cromer has found it impossible to contest the election for the Lord Rectorship, and his Lordship's decision to withdraw from the contest has caused universal regret, which, however, is modified by the fact that the Conservative students have approached Lord Kelvin, who has consented to become the Unionist candidate, as there is no impediment to his being returned as Lord Rector, as he has recently resigned his chair as Professor at the University. As it will be fully a month yet before the students will be up, it is not quite fully known how they will, as a whole, consider the change of candidates, but at the same time the feeling among Conservative clubmen in town is that Lord Kelvin's popularity will make him even a more favourable candidate than Lord Cromer, as the occasion will thus enable the students to pay the highest honour in their power to a favourite teacher and friend, both to themselves, to the University, and to the world generally.

LARGE BEQUESTS TO THE GLASGOW INFIRMARIES.—The agents for the trustees of the late Mr. Alexander Boyack, of Partick, Glasgow, have intimated that the residue of the deceased's estate has been bequeathed in equal proportions to the Glasgow Royal and Western Infirmaries; and it is further stated that the bequests represent a sum of £13,500 to each infirmary. Lately, the Royal Infirmary has fallen heir to very large sums of money, which ought to go far towards the rebuilding of the infirmary, unless the directors put them into the sinking

fund, and go a-begging for more funds to carry out the reconstruction scheme. With regard to the reconstruction the matter seems to be at a standstill, in consequence of which complaints are being freely made regarding the undue delay on the part of the managers and professional staff in settling the plans of the interior which must first of all be completed before any practical step can be taken by the executive committee of the subscribers towards obtaining elevation plans. The explanations given at a recent meeting were ascribed to the difficulties experienced by the managers in satisfying the many requirements demanded in a modern hospital; it is, however, expected that the block plans will be in the hands of the executive not later than the end of October.

Correspondence.

THE ALLEGED INCREASE OF LUNACY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—My attention has been directed to three editorials of very grave importance, published respectively in your issues of August 16th, 23rd, and 30th, on "the alleged increase of Lunacy," my name being mentioned in connection therewith. It is a matter for congratulation that a journal of such high standing has taken up the question and opened a debate upon it in a way which I venture to predict will eventually lead to far-reaching results. As a close student of this painful subject, for a long series of years, and one who contends that the increase is not only real, but of great magnitude, I hope you will give me space for a statement in your columns, which I will make as brief as possible.

The article of August 16th deals with the fifty-third, the last report of the English Lunacy Commissioners, which, like all their reports, *from first to last*, shows a substantial annual increase in the number of registered insane. This report begins as follows:—"The total number of lunatics in England and Wales on January 1st, 1899, was 105,086, being an increase on the corresponding number on January 1st, 1898, of 3,114, the largest increase we have yet had to record." The second article opens with the following observation:—"We are driven irresistibly to believe that sooner or later the conclusion which will infallibly impress itself upon the public is that insanity is not increasing." I have great respect for the authority of the MEDICAL PRESS AND CIRCULAR, but I must distinctly and emphatically traverse this statement, or rather opinion.

You say: "Mr. Corbet, M.P., who has written much on the subject, appears to rely mainly on the official statistics." And again: "Mr. Corbet is going on the broad ground of a crusade in the cause of humanity." Both these assertions are strictly accurate, and constitute in my judgment a solid foundation. Basing myself upon official statistics, and in the cause of humanity, I have through the medium of papers published from time to time in the *Fortnightly Review*, the *Westminster Review*, and other magazines, endeavoured to bring the public mind to realise the terrible fact of the progressive increase of insanity. The subject is such an exceedingly distressing one that very few outside of those who are immediately interested care to read about it or to familiarise themselves with the gruesome details.

For myself, except by giving prominence to the statements of high medical authorities on the predominant factor in the propagation of insanity (heredity), I have never ventured beyond statistical facts, feeling, as a layman, unqualified to deal with psychological mysteries.

The following passage in the article of August 16th has particularly impressed me:—"In the cause, and for

the sake of a great variety of interests, it is now obviously desirable that the much-debated question of insanity should, if not cleared up—which it can never quite be so long as the existing conditions of human nature exist—be at least put on a more satisfactory basis." This is wise counsel, and the readers of the MEDICAL PRESS AND CIRCULAR will do well to take it seriously to heart. The first thing to be cleared up, however, is whether the immense increase of the numbers of registered lunatics, coupled with the great cost of providing expensive and ornamental asylum accommodation for them, together with the large annual increase of maintenance expenditure, indicates an actual increase of lunacy or not.

In one of its articles the MEDICAL PRESS AND CIRCULAR says: "We know the greatest statistician this country ever produced (Dr. Neilson Hancock) could prove anything" from statistics. This is a doubtful compliment. My first paper on the subject was read at a meeting of the Statistical Society of Ireland in 1874, presided over by Dr. Hancock, whose authority as a statistician could not be doubted. At that time—to come to close quarters with the question of real or apparent increase—the registered insane, in Great Britain and Ireland, were, in even numbers, 77,000, having advanced to these figures from 55,500, at which they stood at the beginning of the preceding decade—thus showing a rise in ten years of 21,500. This rate of increase has gone on, without intermission, from year to year, and decade to decade, until the numbers have reached, in even figures, the enormous total of 139,700, England 105,100, Ireland 19,600, Scotland 15,000, or an actual increase in round numbers of 63,000 insane persons. For a long series of years the annual increase averaged about 2,000, but for the last five years it has risen to 3,600, while in the last year of all, namely 1898, the increase has run up to 4,150, the largest ever recorded. It is difficult, in the face of these figures, to see where any room for doubt as to the reality of the increase exists. Especially when one reflects that concurrently the asylums have been doubled in number, more than doubled in capacity and expenditure, and are yet unable to keep pace with the demands upon their resources.

The accumulation of numbers from a variety of causes it still, it appears, chiefly relied upon by the upholders of the "apparent increase" theory. It cannot be denied that the prolongation of the lives of the insane consequent upon improved methods of treatment, the comforts by which they are surrounded, and the nutritious food they get must necessarily cause some accumulation of numbers; but a careful study of the information furnished by the Medical Officers of Asylums will convince any reasonable mind that the true cause of the increase is to be found in quite another direction.

The Special Report of the Inspectors of Lunatics called for in 1893 by Mr. John Morley, then Chief Secretary for Ireland, and furnished from information supplied by the Resident Medical Superintendents of District Asylums, which is before me as I write, contains incontestable proof not only of the reality of the increase but of its origin and magnitude. Of the twenty-two asylums, most of them having had to be enlarged several times in consequence of overcrowding, all had a substantial increase to record, heredity being the main cause assigned.

The Richmond district was naturally given the greatest prominence. Here is what the inspectors had to say about it:—"The actual increase in the number of persons of unsound mind under treatment in this asylum during the last ten years has been remarkable—rising from 1,055 at the end of 1883 to 1,467 at the end of 1892." The inspectors go on to observe:—"The question of heredity as a source of causation is discussed with much force and intelligence in the report, but no sufficient body of specific facts is, it is stated, available to throw light on the point as to whether the improved treatment of the insane may not indirectly tend to perpetuate, or at least increase, the prevalence of insanity. At the same time. . . it is not thought that the facts warrant the conclusion that there has been

during the period any very marked increase in the tendency to insanity amongst the inhabitants of the district."

These are ominous reflections, indicating, as they do, a possibility that the present costly system of housing, treating, and curing (?) the insane may be after all entirely wrong; that so far from tending to arrest the spread of insanity this lavish expenditure has had an opposite effect, resulting, as it has done, in a great annual increase in the numbers of the insane population.

What is the fact? Since those reflections were made by the Inspectors who described the increase of 412, for the ten years ending 1892 as "remarkable," the increase in the Richmond district has further increased by 500, not in ten, but in seven years.

It is necessary to make a brief retrospect in order to realise how universal and continuous the increase has been. On examination before the Select Committee of 1859, when the registered insane in England and Wales were only 35,982 as against 105,086 at the present time, Lord Shaftesbury, who filled the office of Chairman of the English Lunacy Board for forty years previously, stated, even at that period: "The increase of lunacy is certainly unquestionable," prefacing his reply to the question (No. 51) by saying, "I am almost afraid of giving an opinion, as it may be the commencement of the most awful controversy, for there is a great difference of opinion on that point." The "awful controversy" predicted by Lord Shaftesbury has been slow in coming, owing to a variety of causes, but it has come at last, and here we are, forty years after, debating whether an increase from 35,982 to 105,086 in England and Wales with proportionate increases which bring the total in Great Britain and Ireland up to nearly 240,000, is real or only "apparent." Every way one turns it is an all-round increase—increases of numbers, of asylums, of expenditure, of admissions, of discharges, of deaths, and the worst feature of it is, that in spite of all that human sympathy and medical science can do the increase under each of these heads grows larger and larger every year, like a ball of snow that gathers bulk as it progresses. All this, as suggested in the MEDICAL PRESS AND CIRCULAR article of August 16th, requires to be checked, but how is it to be done so long as the fact of any actual increase is denied, while the only official solution offered is to keep on building costly asylums to provide accommodation *ad libitum* for the ever increasing increase of numbers? The disentanglement of this most perplexing problem rests with the medical and surgical professions, who alone are qualified to consider it and to suggest a remedy for the evil. As all attempts made in Parliament to induce the Government to promote an international conference on the subject have failed, the medical and surgical bodies in Ireland might themselves take the matter in hand.

In conclusion, I am not an alarmist, at least not a false alarmist, but simply one who has had special opportunities of noting the increase of insanity for over thirty years, and can now only raise the danger signal.

I am, Sir, yours truly,

W. J. CORBET.

Spring Farm, Delgany, Co. Wicklow.

CURIOUS DEADLOCK IN A LONDON PARISH.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—There is nothing so very singular in a difference of opinion between the Local Government Board and a sanitary Board which is attended with a certain amount of delay in settling matters as to constitute a "curious deadlock." There has been no interruption to sanitary administration in the St. Olave's District. That might have been the case if the St. Olave's District Board had not had the good sense to appoint a temporary Medical Officer of Health to act during the holidays, and until the difference between that Board and their own medical officer had been determined. The Board selected me, without my

knowledge or consent, presumably because I was already acquainted with the district, resided close to it, and was in a position to act at once, if any emergency arose. I am pleased to inform you that the course adopted involved no pecuniary loss to Dr. Bond, whose salary is paid in full. If that had not been the case I should have been happy to have acted for him. If you object to Dr. Bond being permanently appointed to two districts, or to my being temporarily so, I would remind you that there are several districts in London and elsewhere, under the charge of one Medical Officer of Health, in which the area, population, and ratable value exceed that of Holborn, St. Olave, and Bermondsey combined. It is not correct to say that my energies are divided between the cases of private practice and the sanitary charge of Bermondsey, as I am not engaged in private practice, and the Vestry has not contracted with me, and does not pay me, for the whole of my time. Neither is it the fact that important health prosecutions in Bermondsey are generally conducted by one of the subordinate inspectors. They are conducted by the clerk and solicitor, with the assistance of the Medical Officer of Health and the Chief Sanitary Inspector. In minor cases the magistrate is generally satisfied with the evidence of the Inspector only, which I believe is customary in other districts. All prosecutions are directed by the Vestry, on the report of the Public Health Committee, after hearing the opinion of the sanitary officers.

I am, Sir, yours truly,

JOHN DIXON.

183, Jamaica Road, Bermondsey,
September 21st, 1899.

[The facts that Dr. Bond is suspended by St. Olave's, while his reinstatement is ordered by the Local Government Board, that Dr. Bond is drawing salary for doing nothing, and that Dr. Dixon has been appointed to supersede Dr. Bond appear to justify the term "deadlock." We do not blame Dr. Dixon for holding a "half time" appointment, but we altogether condemn the system that permits the existence of such a post. Our impression that Dr. Dixon is not conspicuous in sanitary prosecutions in his own parish may possibly be a misconception, but the actual evidence in court of the Medical Officer of Health is usually regarded as crucial. We are glad to publish Dr. Dixon's statement that he is not engaged in private practice, as the ground is thereby to some extent cleared. The general impression in his own district, however, is that, at any rate, until quite recently, he has been engaged in extensive practice.—Ed.]

HOSPITAL REFORM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It will be a source of gratification to many of your readers to know that there is every prospect of a successful gathering at our conference on the 10th and 11th of October next. Our aim has been to have the subjects set down discussed by men who have had personal experience of them; and when I mention the following names it will be allowed that we have been successful in that respect. Dr. Arnold Lea, Manchester; Dr. Bertram Rogers, Bristol; Dr. Brown Ritchie, Manchester; Colonel Montefiore, London; Mr. C. W. Warren, London; Dr. Francis Waring, Brighton; Dr. Richardson Rice, Coventry, Mr. Hawkins-Ambler, F.R.C.S.E., Liverpool, are gentlemen who have devoted a great deal of time and study to the subjects which they propose to treat. Mr. Timothy Holmes, F.R.C.S., has, I am glad to say, promised to preside at one of the meetings, and the Rev. Russell Wakefield, Rector of St. Mary's, Bryanston Square, at another. The absence of so many men from home at this time has prevented our making arrangements for the chairmanship of the third meeting, but I have no doubt that we shall succeed in obtaining the services of a competent chairman before long.

Having done so much on our part, it now remains for the general practitioners of the country to support our efforts. Conferences in London cannot be held without incurring expenses, and we shall be glad to have contributions towards defraying them.

I am, Sir, yours truly,

T. GARRETT HORDER,
Hon. Sec.

Cardiff, September 23rd, 1899.

THE ABUSE OF MEDICAL CHARITIES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—A few weeks ago you referred to a case in which Sir Sydney Waterlow maintained that a clerk in receipt of £200 a year would be unable to pay a surgeon the fee for an ordinary operation. It so happens that I am in possession of the facts of a case where an applicant was rejected from St. Bartholomew's Hospital some weeks ago, and in my own mind I have little doubt he was the "clerk" to whom Sir Sydney referred. The facts are these. Some years since, this person had a son who suffered from nasal obstruction. He obtained a personal letter of introduction from a private patient to one of the surgeons of the hospital. The boy went into hospital, and the surgeon performed the operation. This same applicant wanted a similar operation performed on a second son, and naturally turned again to St. Bartholomew's. On this occasion, however, his circumstances were taken into consideration by the committee, who rejected his application, and the surgeon turned a cold shoulder to him. He then went to a small special hospital, and one of the surgeons performed the operation for five guineas, while four guineas a week was paid for the boy in a private hospital. This clerk, it is true, has only £200 a year salary. His wife, however, is a Court milliner, and part of their house is let off to consultant at a high rent. They live in a style that cannot be approached by many a consultant and specialist and general practitioner whose interests are ignored by philanthropists of Sir Sydney Waterlow's stamp.

I am, Sir, yours truly,

London, September 23rd, 1899.

IGNOTUS.

NURSES OF THE LATEST FASHION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Allow me to endorse what Dr. Walsh has said with regard to Mr. Gant's article on what he is pleased to call "nurses of the latest fashion." As a contribution to the economics of nursing, Mr. Gant can hardly be expected to be taken seriously, despite the all-embracing title he has selected. If that gentleman had headed his paper "Some Nurses of the Latest Fashion," and had stated clearly whether the characters were imaginary or drawn from active life, then possibly no great exception could have been taken to the subject, although doubtless opinions might have differed as to the good taste or otherwise of his contribution. As matters stand, if Mr. Gant has really had any experience such as he describes, it would seem to be his duty to the profession to publish the names of the nursing institutions concerned. But even in that case, to brand all nurses as bad because a few may have criminal tendencies does greater credit to Mr. Gant's imagination, than to his reasoning powers. The title of Mr. Gant's articles, to which I have already alluded, makes it impossible to conclude that his attacks are not levelled at the entire nursing sisterhood. I am sorry that such egregious material should find any place in the pages of a sober medical periodical.

I am, Sir, yours truly,

SYDNEY STEPHENSON.

33, Welbeck Street, W.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Although I agree with your correspondents, Dr. Walsh and Dr. Bateman, as far as they appear to go, that nurses of the latest fashion are an arduous class of

workers, there can be no doubt that the tendency of the majority of the present day is to assume a false position before the public, nor do I think Mr. Gant can be accused of any exaggeration on account of the style in which he has so ably depicted them.

I remember myself, some years ago, attending a rector's wife, since deceased, who resided in a country village, and on that occasion I suggested at the bedside milk as an article of diet, whereupon, to my surprise, the nurse suddenly blurted out something about milk causing phlegm. The family being highly educated and somewhat highly connected I thought I displayed better form by remaining mute, but on going down stairs the son, who, by the way, was a late Fellow of his college, took me to task for not showing more decision. I, however, pointed out to him the necessity of preserving equanimity in a sick room, and advised him to quietly follow the directions, but told him plainly to laugh up his sleeve, and he appeared satisfied.

On another occasion more recently in this very district I happened to attend a confinement, and to my great astonishment on visiting the next day the room was taken possession of by two females, one of whom turned out to be the superintendent, who was attired in a somewhat ghastly uniform, the like of which I had not seen, and who had been called in as a kind of consultant, but although I had the responsibility of the case, I was treated as though a nonentity.

Many a few of your readers may have read the life of the late Sister Dora, a name that will be justly cherished in this country, but it is impossible to conceal the fact that there was here a type of mind which made it difficult even in an organised institution to conduct business, and, if I am correct, it is easy to conceive the difficulties which confront the majority of medical practitioners with "nurses of the latest fashion," and this is, of course, accounted for owing to the difficulty of keeping the female mind under proper control, so, under all circumstances, I think now if your correspondents need shed tears over a class whom the present state of society regard as indispensable.

I am, Sir, yours truly,

CLEMENT H. SERS.

Queen's Road, Peckham, S.E., September 25, 1899.

[It is only fair to Mr. Gant to point out that, in his introductory remarks, he expressly repudiated any desire to formulate an indictment of properly trained and certificated nurses, or of nurses as a class. His strictures obviously apply only to certain, possibly numerous, exceptions, occurring in the ranks of those whom we may dub the unqualified. It is well-nigh inconceivable that women who have been through the prolonged and exacting training and supervision which certification implies, or ought to imply, would display such deplorable moral characteristics. The weakness of moral fibre which characterised Mr. Gant's heroines would scarcely have escaped notice during their period of probation, and we all know the severity with which such delinquent tendencies would be treated by the ladies who direct our large nursing institutions. We repeat, then, that Mr. Gant's remarks were intended to warn the profession only against *soi-disant* nurses, whose aptitudes and trustworthiness are, to put it gently, matters of conjecture. Ed.]

The Mortality of Foreign Cities

THE following are the latest official returns, and represent the last weekly death-rate per 1,000 of several of the populations:—Calcutta —, Bombay 37, Madras 31, Paris 16, Brussels 19, Amsterdam 12, Rotterdam 20, the Hague 14, Copenhagen 24, Stockholm 17, Christiania 21, St. Petersburg 22, Moscow 27, Berlin 25, Hamburg 19, Dresden 26, Breslau 30, Munich 24, Vienna 18, Prague 24, Buda-Pesth 21, Trieste 25, Rome 13, Turin 16, Venice 16, Cairo 45, Alexandria 38, New York 16, and Philadelphia 16.

Obituary.

SURGEON-MAJOR-GENERAL LITHGOW, M.D., C.B.

MEDICAL circles in Edinburgh were last week surprised to hear of the sudden death of Surgeon-Major-General Lithgow at his country house near Malrose. He had only been ill for a few days, and little word of the fact had reached Edinburgh or the Edinburgh Royal Infirmary, of which he had been the medical superintendent since December, 1892. His military career was most distinguished and successful; the *Scotman* gives the following description:—"Major-General Lithgow could almost be said not to have had any illness of consequence until the last and fatal attack occurred. He was attached to the Army for thirty-six years, frequently on active and foreign service, and never required a single day's sick-leave." In his last post he proved himself just, able, seemingly severe as befitted his responsible position in the control of a vast institution, in reality one of the kindest of men, duty for him came before pleasure, went often against inclination, but was done, and done rightly.

MR. JAS. VOSE SOLOMON, F.R.C.S., OF BIRMINGHAM.

WE regret to announce the death of Mr. James Vose Solomon, F.R.C.S., who died on Wednesday at his residence, Handsworth, at the age of 82. Mr. Solomon was a native of Birmingham, where his father was a physician practising in this city. He studied at Birmingham and St. Bartholomew's. In 1838 was admitted to the licentiate of the Society of Apothecaries. He also became a member of the Royal College of Surgeons, England, and in 1854 he was elected a fellow of the college. Among general appointments he held were those of surgeon to the gaol, to the General Dispensary, to the Orthopedic Hospital, and to the Birmingham Police. In the development of the Birmingham Eye Hospital he played an important part, and for many years he was the honorary surgeon to the hospital. For some years he was the professor of ophthalmic surgery at Queen's College. In 1869 he founded the Birmingham and Midland Counties Branch of the British Medical Association, of which he was the first president.

Literature

A SYSTEM OF MEDICINE. (a)

THIS system of Medicine is now rapidly reaching its completion, and as this is the penultimate volume the Editor's troubles will soon be at an end. He still continues to bemoan his own shortcomings, but he should take heart of grace and remember that he is now fairly convalescent. We are not aware that any sequelae follow the production of a work of this description, and we have no reason to suppose that there will be a relapse in the shape of a System of Forensic Medicine, or even of *Materia Medica*. The compilation of this work must have been in itself a liberal education, and if the Editor has read all the contributions of his "many writers," he should have added very considerably to his stock of knowledge.

This, the seventh volume of the System, is devoted entirely to diseases of the nervous system, a subject which was commenced in the preceding volume, and will be concluded in the final one. The present instalment contains Diseases of the Spinal Cord, Diseases of the Brain, and a somewhat indefinite group called "Other Diseases of the Nervous System." Many of the articles are exceptionally good, and, taking it all round, it is probably the best and most important volume of the series. Some of the contributors are "nerve specialists," whilst others are physicians attached to general hospitals. The article on "Myelitis," by Dr. Frederick Taylor, of

Guy's Hospital, is a sound and careful bit of work. He explains very clearly the nature of the different varieties of this disease, and the reader is made familiar with the importance to be attached to acute and subacute, chronic, transverse, diffuse, focal, and disseminated inflammation of the spinal cord. The charm of this contribution is that that the information is conveyed in language which is comparatively free from technicalities.

The article on "Diver's Paralysis or Caisson Disease," is contributed by Dr. Andrew H. Smith, of New York, who had exceptional opportunities of studying the disease in connection with Brooklyn Bridge and the Hudson River Tunnel. His suggestion that the patients should be treated by placing them under atmospheric conditions similar to those which produced the disease is ingenious. He thinks that a chamber should be constructed in which a cot containing the patient could be placed, and to which compressed air could be admitted through a pipe connected with the caisson. The chamber would resemble a horizontal boiler of convenient dimensions, having a door or opening at the end. It would be properly ventilated, and would be lighted by electricity from without, the light being admitted through a series of portholes or bull's eyes. It would, of course, be furnished with a telephone so that communication could be kept up between the patient and his attendants. With the addition of a portable earth-closet and other similar appliances it could be made quite a charming temporary residence.

The article on "'Disseminate' Sclerosis" is by Dr. Risien Russell. The nomenclature strikes us as being somewhat strange, for by most writers the disease is spoken of as "disseminated sclerosis," whilst by others it is called multiple or insular sclerosis. This is one of the great drawbacks of the nerve specialist; he never seems to be happy unless he can coin a new name for an old disease, and the result is that his nomenclature becomes day by day more and more complicated. The author passes somewhat lightly over the differential diagnosis of disseminated sclerosis and paralysis agitans, and thinks that, in spite of tremor being common to both, it is not easy to suppose that any real difficulty in diagnosis could arise. As a matter of fact, students at examinations constantly do experience this difficulty, and are rarely able to state the points which distinguish the two diseases.

"Tabes Dorsalis," by which, of course, is meant locomotor ataxy, is the joint production of Dr. Ormerod and Dr. Mott, the latter being responsible for the pathology and morbid anatomy of the disease. Both contributors have done their work well, and the article is one of the best in the book. Dr. Ormerod is by no means satisfied that all cases of locomotor ataxy are syphilitic in origin. He points out that it is impossible to maintain that tabes is pathologically identical with syphilis, and urges that generally speaking, it is not amenable to anti-syphilitic treatment. The ever-increasing tendency to name symptoms after some particular individual is well illustrated by the complaint. Thus we have "Westphal's sign," or loss of knee-jerk, the "Argyll-Robertson's sign," reflex iridoplegia, or loss of pupillary reflex under the stimulus of light, "Romberg's symptom," or staggering when the eyes are shut, and finally, "Charcot's disease," or joint. Moreover an allied condition, Hereditary ataxia is commonly known as "Friedreich's Disease" or congenital ataxia. To make things still more complicated in some cases, two totally distinct diseases have been named after the same individual and in more than one instance several authors claim the honour of having the same disease named after them. This savours of puerility, and does not add to the dignity of neurology. Dr. Ormerod has, of course, simply followed a well-established custom in naming names, and has done nothing to add to our difficulties. Both he and his colleague have done their work well, and Dr. Mott's contribution to the pathology of tabes is of the greatest possible value.

Syringomyelia, or cavity of the cord, is not an especially interesting subject. The most prominent symptom of the complaint is what Charcot called "dissociated anaesthesia," that is, a loss of sensation of pain and

(a) "A System of Medicine." By Many Writers. Edited by Thomas Clifford Allbutt, M.D., F.R.C.P., F.R.S. Vol. VII. London: Macmillan and Co. 1899.

temperature in a part, with retention of tactile sense in the analgesic area. The majority of the patients do not know that they suffer from this condition until their attention is called to the fact. It is urged that the sense of pain is a great protection as it gives warning of injury and assures care and rest of the part. If a man is burnt and does not experience any pain he is generally satisfied, whereas he ought to recognise that he is suffering from an abnormal condition and take steps to get himself cured?

There is some doubt as to whether amyotrophic lateral sclerosis constitutes a separate disease apart from progressive muscular atrophy and chronic bulbar paralysis, but Dr. Beevor has made the most of the material at his disposal, and contributes a very interesting article.

Infantile Paralysis, or Poliomyelitis Anterior Acuta is dealt with at considerable length by Dr. Allan Starr, of New York, who enters pretty fully into the subject of treatment. He thinks that massage is of the utmost importance in these cases. He makes a suggestion, however, which causes us to wonder if he employs the term in the same sense that it is employed by Continental writers. He says that among the poorer classes it is well to instruct the mother how to do this so that it should be given with persistence. This, of course, is absurd if he is using the term massage in the sense in which it is employed by Metzger, Von Mosengeil, and other writers. The statements made by an American writer on massage in an early volume of this work were of such an extraordinary description that one cannot help thinking that the term massage is used by a certain section of the profession in the United States to indicate a mode of procedure to which the name would not be applied in this country. If this be so it is certainly strange, for Douglas Graham, of Boston, is a recognised authority on the subject, and would certainly not countenance the idea that a person without anatomical or physiological knowledge would be competent to treat a case of infantile paralysis by massage.

Ferrier's article on the "Regional Diagnosis" of cerebral diseases is an admirable summary of the whole subject. It must be remembered that it is only within the last twenty years that the chaotic darkness of clinical medicine has been illuminated by experimental methods in this particular department. Before that little or nothing was known on the subject beyond the facts that in hemiplegia the lesion was in the opposite hemisphere, that a lesion of Broca's convolution was the cause of certain forms of aphasia, and that Jacksonian epilepsy was due to irritation in the Rolandic area. Now all this is changed and thanks to the researches of Ferrier, Beevor, Horsley, and Schäfer, we know exactly what symptoms, irritative and destructive lesions of the various lobes and centres of the brain will produce. It is an enormous advance and one of which English physiologists naturally feel proud. It is a curious circumstance but one which has been ascertained experimentally and verified clinically, that injury, even amounting to removal, of the prefrontal region, gives rise to no discoverable symptom either sensory or motor. Injuries to other regions—the Rolandic, for example—produce well marked effects, all of which are duly set forth in this article. We have only one criticism to offer. We are afraid that the average reader who has not a brain, or a working model of a brain, before him will have much difficulty in following Dr. Ferrier's article without constant reference to the diagrams on p. 274. It is annoying to have constantly to refer back, and the difficulty could easily have been obviated by printing these outlines on a separate sheet, set out in such a way as to be visible to the reader at any point of the article. We are glad to find that Dr. Ferrier acknowledges his indebtedness in the preparation of his contribution to Dr. W. Aldren Turner and to Dr. Ashley Mackintosh. This is as it should be, for it is only right that the devil should have his due. We trust that all the other contributors have been equally conscientious.

Another first-class article on the "General Paralysis of the Insane" is by Dr. Savage and Dr. Goodall, of Caermarthen, whilst Sir Wm. Gower's deals with the subject of epilepsy. Epilepsy affords ample scope for

the discussion of treatment, of which the author has availed himself fully. He still thinks well of borax, which he gives in doses of from 4 to 10 grams three times a day. He mentions the psoriasis which it so often induces, and finds that it speedily disappears when arsenic is added to the borax mixture.

The subject of "Chorea" is dealt with by Dr. Risien Russell, who contributes seven articles to this volume, not including an article of which he is joint-author. This is certainly rather a large allowance for a physician whose name until the last year or two was comparatively unfamiliar to the medical reader. We do not suggest for one moment that the confidence is misplaced, or that the work is not admirably done, but there are now so many young physicians devoting themselves to the study of neuropathology, that it seems almost a pity not to have given more of them an opportunity of distinguishing themselves.

One word more and we have done. These volumes when first issued presented an extremely attractive appearance in their scarlet and gold covers. Some of them, although not exposed to sun or damp, and kept in a room not lighted by gas, now present a very dingy appearance, the original scarlet, especially at the backs, having assumed a dirty brown and in places a blackish hue. This is a great pity, and probably points to some faulty method in the binding department.

We shall look forward with much pleasure to the publication of the eighth and concluding volume of this valuable and useful System of Medicine.

SELECTED PAPERS ON STONE. (a)

THE first of these interesting papers is an abstract of the Bradshaw Lecture, Royal College of Surgeons, 1896. In it the author does not entirely view with satisfaction the almost entire disappearance from modern surgery of lateral cystotomy. Among other subjects, castration and vasectomy for enlarged prostate are dealt with, and a note of warning is given to surgeons on the uselessness of either operation in cases of fibrous or carcinomatous prostate; the utility of perineal lithotomy in some cases is mentioned, and also the importance of litholapaxy in children, and regrets are expressed that the Röntgen rays have not been found sufficiently reliable for the diagnosis of vesical calculus. The next paper contains a dissertation on a table of 110 cases of litholapaxy, after which comes an article on vasectomy, followed by an interesting chapter on sacculi and pouches of the urinary bladder. A short paper is devoted to cases in which a non-malignant communication exists between the bladder and intestines; the next paper describing a new operation for extroversion of the bladder contains a very instructive case; this is followed by chapters on treatment of albuminuria by reni-puncture, on some suppurations of the urinary organs, on urethral stricture and its treatment, on some forms of acute urine fever; on a mode of stretching some urethral strictures, this includes a description of an instrument constructed on the lines of a Holt's dilator, which should admirably answer the purpose for which it is intended; next come some notes on hæmaturia, followed by an instructive case of large pelvic hydatid treated by perineal incision and drainage; the last paper deals in a practical way with urethral irrigation. These various papers condensed in a volume of 190 pages will well repay perusal, the precepts laid down being always sound, and the author's ideas being always set forth in a practical, plain, and concise manner. The illustrations are not many, but they bring under the reader's eye very clearly the various conditions, &c., which they are intended to depict.

"ASEPTIC SURGERY." (b)

IN the preface to the second edition of this very useful work the author says that no alterations of any moment have been made in it, yet we are glad to give a hearty wel-

(a) "Selected Papers on Stone, Prostate, and other Urinary Disorders." By Reginald Harrison, F.R.C.S. 190 pp. London: Churchill.

(b) "Aseptic Surgery." By C. B. Lockwood, F.R.C.S. 246 pp. Edinburgh and London: Young J. Pentland.

come a second time to a book which contains such a large amount of invaluable information and of useful advice to all, from the highest to the lowest, who practise the art of surgery. Almost the first phrase in the introduction should be regarded as a golden rule; Mr. Lockwood writes:—"It is quite impossible to practise aseptic surgery with success unless not only the surgeon and his assistant, but also the sisters and the nurses have a clear and distinct knowledge of its principles." Starting from this standpoint it is evident that the perusal of the succinct but lucid descriptions in the 200 odd pages that follow will amply repay all those concerned in the author's dictum. Part I. gives a short but very clear account of the various micrococci and bacilli. Part II. deals with the sources of infection divided into infection by air, by water, by contact, by the human skin, with a passing reference to auto-inoculation and to immunity. In Part III. disinfection and antiseptics are dealt with, the author keeping strictly to the definition he had already laid down in his introduction, that the former kills the bacteria outright, whilst the latter prevent or retard their growth. The last Part (P. IV.) is devoted to surgical technics. Some very useful and practical hints are given to the surgeon, to the assistants, to the nurses and sisters. With regard to the disinfection of the skin of the patient we quite agree that it should not be done in a routine manner, for, as the author says, "the methods which are necessary to disinfect the harsh, thick, neglected skin of hospital patients would be harmful to the delicate skin of a child or lady." Next the preparation of the instruments, ligatures, &c., is given, and some surgeons might with benefit bear in mind, as Mr. Lockwood very justly says, "... how irrational it is to disinfect instruments and then allow them to touch what is infected." The author prefers the biniodide of mercury lotion to the perchloride solution, he gives his reasons, and they certainly seem conclusive. A few necessary words are said about the operation itself; the application of the dressings is fully dealt with, and the after treatment briefly touched upon. The last chapter gives a summary of the good results of aseptic surgery. The idea of the whole work may be summed up by a sentence of the author's in dealing with the field of operation. He says:—"An operation founded on the principles of aseptic surgery is a bacteriological experiment."

"ON THE ORIGIN AND PROGRESS OF RENAL SURGERY." (a)

THIS volume comprises the three Hunterian Lectures for 1898, together with a fourth lecture, which was originally published in the *Edinburgh Medical Journal* for January, 1899, and which has been revised with additions. It is hardly necessary for us to say that these lectures, coming from a surgeon whose name is so intimately connected with renal surgery, are well worthy of being published in the form of a book. They practically embody all that is known up to the present day on the subject, together with the lessons the author has derived from his own great experience. The fourth lecture on "Rupture of the Ureter" is specially interesting in view of the rarity of the lesion, and of the difficulty in the diagnosis owing to the paucity of the symptoms; it is at the same time very instructive, and much may be learnt by its perusal and by the consideration of the eleven cases regarded as subcutaneous ureteral injuries, the abstracts of which are given with it. The work contains some excellent illustrations.

"GLEET AND CHRONIC DISEASES OF THE URETHRA AND PROSTATE." (b)

THERE is nothing very new in this little book, but the descriptions of the methods of treatment are good and practical. The application of irrigation to the urethra by means of the instrument used by the author should be of great use, and is well worthy of a trial in trouble-

some cases of persistent gleet. We heartily agree with Mr. Dalton when he says, "the supposed development of stricture from too rapid a cure of gonorrhoea is a myth, the more speedy the cure, the less likelihood of a stricture forming."

LECONS DE CLINIQUE CHIRURGICALE. (a)

THIS volume contains twenty clinical lectures given during August and September, 1897, at the Hotel Dieu, Paris. The author in his preface expresses his regrets that circumstances prevented their earlier publication, and expresses a hope that his readers will find in his work the exposition of new and personal ideas. These hopes will be found ably carried out. In the lecture on Uranoplasty, Delbet discusses at length the question of the age most suitable for operation, and follows Trélat in choosing the sixth year as the most favourable; before that period he considers surgical intervention to be coupled with many dangers, not the least of which is ulterior atrophy of the maxilla. All the following lectures are certainly of great value; among those of special interest we may mention the one on congenital thyro-hyoid cyst, in which the anatomy and pathology of the affection are fully dealt with; the one on cicatricial stricture of the oesophagus in which the advantages of retrograde catheterism of the tube after gastrostomy are fully explained; a very instructive dissertation on fracture of the spinal column, and another on cirroid aneurysm; the text of the lecture on carpus curvus is embellished by several illustrations, which help the reader to realise the anatomy of the displacement; the valvular insufficiency of the internal saphenous vein in cases of varicose veins of the lower limb is brought forward in the twelfth lecture; the next deals in a most efficient manner with the complications and deformity following Dupuytren or Pott's fracture, and the operative measures for their relief; the fourteenth and fifteenth lectures describe intestinal occlusions, the former (illustrated) by twisting of the whole of the small intestine, the latter by chronic obstructions; the next two lectures are taken up by the treatment of hydatid cysts of the abdomen; and, finally, the last two deal with appendicitis and salpingitis and their treatment. The style and language are vigorous, clear, and eminently practical, and the type essentially readable.

YEAR BOOK OF PHARMACY. (b)

OF the leading contents of the volume we may fitly give first place to the account of the liquefaction of hydrogen recently accomplished by Dewar. Its liquefaction has been accomplished by submitting the gas to the combined influence of a temperature of 205 per cent. C. and a pressure of 180 atmospheres, under which it assumed the form of a colourless liquid.

The researches of M. Constan and of von Haussen have resulted in producing a new class of oxidising substances known as percarbonates, of which the potassium salt $K_2 C_2 O_8$ is a good example. It splits up when heated into potassium carbonate, carbonic anhydride, and oxygen, and decomposes water at the ordinary temperature with liberation of oxygen and the formation of potassium bicarbonate.

Messrs. Porsbrand and Richelmann have isolated from coffee a new alkaloid which differs from caffeine by its insolubility in chloroform, its failure to give the mercurial reaction, and by its forming a precipitate with picric acid.

The influence of alcohol on the digestive action of pepsin is discussed by C. Symes and also by R. H. Chittenden, Wendel, and Jackson. The effect of boric acid in retarding the assimilation of proteid and fatty food is shown by the investigations of Chittenden and Gies. The whole book is worthy of careful reading by

the general practitioner, and makes a useful addition to the medical library.

A TRAGIC DEATH

A CURIOUS case of accidental poisoning has occurred to both doctor and patient at Eastbourne, necessitating the holding of an inquest on the body of Dr. Dick of that town. From the report to hand it would appear that on the 14th inst. a patient called at the surgery and was given a bottle of medicine, which she took home. After taking the first dose she became ill, and on Dr. Dick calling next day he was informed of the circumstance. In order to assure his patient that there was nothing wrong with the medicine he drank a quantity in her presence, and before leaving the house took a second dose with the same intent. On his arrival home, however, he fell against the door, foaming at the mouth and betraying other symptoms of poisoning. He had strength enough to suggest the stomach pump, and medical aid was immediately summoned, but he succumbed; while his patient, who had swallowed one dose only of the medicine, recovered. At the time of our going to press we hear the analysis of the medicine showed it to contain a large quantity of strychnine.

Laboratory Notes.

FLUORINE PRODUCTS.

WE have received from Messrs. T. Christy and Co. samples of three new products with fluorine as a basis, viz., Antitussin, Fluor-Rheumin, and Epidermin, together with a substance to which the name Malarin has been given. *Anti-tussin* is an ointment containing difluordiphenyl, and it is introduced as "a certain cure for whooping-cough and diseases of the throat and neck," a rather large order in its vagueness. It is directed to be rubbed in vigorously over the previously-cleaned skin of the neck, breast, and back, and it is said to "cure" whooping-cough in about a week. *Fluor-rheumin* is an ointment containing one in five of fluorphenetol-difluordiphenyl, and when rubbed well into the skin over the affected parts it is claimed to be an exceedingly efficient drug in the treatment of various forms of rheumatism and neuritis. *Epidermin* contains one part of fluoryl and four parts of difluorphenyl mixed with ninety-five parts of a fatty base. It is powerfully antiseptic, and appears to be a preparation well adapted for the treatment of certain affections of the skin. *Malarin*. This is described as a condensation product of acetophenon and phenetidin. In virtue of its molecular constitution it is an energetic antipyretic though practically non-poisonous. Its effects are pronounced even on the normal temperature, and this too in comparatively small doses (4 to 6 grains), without any corresponding influence on respiration or on the pulse. The antipyretic action is associated with a hypnotic effect, which soothes the nervous system at the same time as it reduces the pyrexial temperature. *Malarin* promises to be a useful addition to the series of agents at our disposal for reducing fever and abolishing painful manifestations of various origins.

We should like, however, to enter a formal protest against the system of nomenclature which here reaches its unwelcome apogee. The only admissible plan of naming new products is to select a syllable or syllables from their chemical description roughly indicative of their nature. All names based on supposed therapeutic action are objectionable because they are apt to prove misleading, and they savour far too much of the popular nostrum.

Medical News.

Deaths From Small-Pox at Mexborough.

A DEATH from small-pox is reported from Mexborough in the person of a child eighteen months of age, imported from Hull.

Vital Statistics.

THE deaths registered last week in thirty-six great towns of the United Kingdom corresponded to an annual rate of 21.1 per 1,000 of their aggregate population, which is estimated at 12,786,832 persons in the middle of this year.

Birkenhead 17, Birmingham 25, Blackburn 20, Bolton 22, Bradford 19, Brighton 25, Bristol 16, Burnley 28, Cardiff 16, Croydon 13, Derby 15, Dublin 35, Edinburgh 20, Glasgow 22, Gateshead 25, Halifax 17, Huddersfield 17, Hull 21, Leeds 18, Leicester 19, Liverpool 30, London 18, Manchester 26, Newcastle-on-Tyne 24, Norwich 10, Nottingham 21, Oldham 17, Plymouth 17, Portsmouth 18, Preston 31, Salford 32, Sheffield 21, Sunderland 29, Swansea 20, West Ham 19, Wolverhampton 31. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From measles, 1.4 in Burnley; from scarlet fever, 1.1 in Bradford; from fever, 1.0 in Sheffield, 1.1 in Halifax, and 1.4 in Birkenhead; and from diarrhoea, 5.8 in Hull, 5.9 in Birmingham, 6.5 in Nottingham, 6.9 in Manchester, 7.2 in Liverpool, 8.0 in Brighton, 10.0 in Wolverhampton, and 16.0 in Preston. In none of the large towns did the death-rate from whooping cough reach 1.0 per 1,000. The 73 deaths from diphtheria included 22 in London, 10 in Leeds, 8 in Sheffield, 6 in Leicester, 5 in Birmingham, 4 in Liverpool, and 3 in Portsmouth. Three deaths from small-pox were registered in Hull, but not one in any other part of the United Kingdom.

Stale Medicine.

MR. BRAXTON HICKS, the coroner, recently volunteered the advice to the public never to take stale medicine, he having just recovered from illness caused by a dose of cough linctus which had undergone decomposition.

Gresham College.

THE subject of the lectures to be delivered by Dr. E. Symes Thompson, the Gresham Professor of Medicine, on October 3rd, 4th, 5th, and 6th (6 p.m.), will be "Earth, Air, Water, and Insects in Relation to Disease."

University of Durham—Faculty of Medicine.

AT the Examination for Degrees in Medicine and Surgery during September, the following Candidates passed the Second Examination for the Degree of Bachelor in Medicine—

Honours—Second Class.

Manning, Ernest J., St. Mary's Hospital.
Waters, James B., College of Medicine, Newcastle-upon-Tyne.
Brunyate, Annie T., London School of Medicine for Women.
Clapham, Stanley C., M.R.C.S., L.R.C.P., Guy's Hospital.
Ellis, Henry R., M.R.C.S., L.R.C.P., St. Bartholomew's Hospital.
Emmerson, William M., College of Medicine, Newcastle.
Fox, Ida E., London School of Medicine for Women.
Molony, Lucy S., London School of Medicine for Women.
Nevin, Robert W., College of Medicine, Newcastle.
Robertson, Monica L. M., College of Medicine, Newcastle.
Rutherford, Thomas C., St. Thomas's Hospital.
Benton, Ralph M., College of Medicine, Newcastle.
Turner, Sydney D., M.R.C.S., L.R.C.P., St. Thomas's Hospital.
Walker, Norman B., College of Medicine, Newcastle.
Wetherell, Marmaduke C., Guy's Hospital.

Society of Apothecaries of London—September, 1899.

THE following candidates passed examinations during September, in:—

Surgery.—N. H. Bonnerjee (Sections I. and II.), A. F. Carlyon (Sections I. and II.), A. McC. Dallas (Section I.), E. F. Lamport, A. Orme (Section II.), and W. Rigby (Sections I. and II.).
Medicine.—W. P. Allen, A. F. Carlyon (Sections I. and II.), F. Elias, F. Marriott, H. J. Pickering (Section II.), W. Rigby (Sections I. and II.), L. L. G. Thorpe, H. E. Weston (Section II.), and H. Whittaker.

Forensic Medicine.—W. P. Allen, A. F. Carlyon, R. F. Ellery, F. Marriott, W. Rigby, and L. L. G. Thorpe.
Midwifery.—F. P. Bush, W. Rigby, W. C. Stanham, and G. H. Watson.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—N. H. Bonnerjee, A. Orme, W. Rigby, A. F. Carlyon, and L. L. G. Thorpe.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS and CIRCULAR, may now be had at either office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

REPRINTS.—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them, at half the usual cost, on application to the printers before the type is broken up.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

FILTHY LUCRE.

THE bacteriology of coins would certainly constitute a fruitful field of investigation. If one would take the trouble to wash a handful of money in a detergent alkaline solution, the turbidity of the resulting liquid would not fail to surprise. In a more enlightened age the Government may perhaps make arrangements for the periodical cleansing of the coinage, but this very hygienic measure is not yet within view. One can only wonder at the carelessness of bus conductors and others who deliberately stick coins between their lips while counting out the change.

DR. E. WHITE (Burlington, Canada).—The subject of "Dry Catarrh of the Middle Ear" will be found fully treated in an article which appeared in the first week in January, 1898, of this journal by Dr. Dundas Grant.

THE INDIAN MEDICAL SERVICE.

THE next Examination for Appointments in Her Majesty's Indian Medical Service will be held in London in February next. Regulations may be obtained at the India Office, particulars of which will be found in our advertisement columns.

L. G. M.—Night terrors in the young are very commonly associated with the presence of intestinal parasites, but the condition has also been noticed in association with circulatory troubles, such as incipient cardiac disease. Circulatory weakness, associated with too rapid growth, has also been credited with its production.

THE WEIR-MITCHELL TREATMENT

A CORRESPONDENT asks whether there exists a recent monograph on what is commonly described as the Weir-Mitchell treatment. If not, where can detailed information thereof be obtained?

DR. E. N.—Carbolised solutions, whether in oil or water, dull the edge of all cutting instruments. If left long in ordinary spirit steel instruments rust. It is best to keep surgical needles in a saturated solution of ordinary washing soda, or, if preferred, in a saturated solution of chloride of calcium in rectified spirit.

THE TREATMENT OF STUTTERING.

M. L. asks whether there is any institution in London where a working man who stutters could undergo a course of training with the object of overcoming the defect. He adds that anything beyond nominal fees would be quite out of the question in this case.

NURSE J.—To remove blood from the hands always use clean water and a nail brush first, as soapy water does not readily dissolve inspissated blood.

SOMEWHAT IGNORANT!

DOCTOR (to dispensary patient): "Now, remember, my man, three or four drops of this mixture three times a day—and inhale." Patient: "Be I to take it in four or six ale, gov'nor?"—*Exchange.*

Vacancies.

Bethnal Green Infirmary.—Medical Superintendent for the New Infirmary, Cambridge Heath. Salary £500, with unfurnished apartments, coals, lights, and washing. Apply to the Clerk to the Guardians, Offices, Bishop's Road, Victoria Park, N.E.

Borough of Maidstone.—Medical Officer of Health. Salary £200 per annum and £150 a year for water analysis. Applications to the Town Clerk, Maidstone.

Cumberland and Westmoreland Asylum, Garlands, Carlisle.—Junior Assistant Medical Officer, unmarried. Salary £100 a year, with board and residence.

Durham County Asylum, Winterton, Ferryhill.—Assistant Medical Officer, unmarried. Salary commencing at £140, with board, lodging, washing, and attendance. *2*

Egyptian Government School of Medicine, Cairo.—Professor of Ophthalmology. Applications to F. G. Hallett, Esq., Secretary, Examination Hall, Victoria Embankment, London.—(See advert.)

Govan District Asylum, Crookston, near Paisley.—Junior Assistant Medical Officer. Salary commencing at £100 a year, with rooms, board, attendance, and laundry.

Hospital for Consumption and Diseases of the Chest, Brompton.—Resident House Physicians for six months. Honorarium £25 each. Also an Assistant Resident Medical Officer. Salary £100 per annum, with board and residence.

Nottingham Hospital for the Insane, the Coppice.—Assistant Medical Officer, unmarried. Salary £150 per annum, with apartments, board, attendance, and washing.

Leeds Hospital for Women and Children.—Non-resident House Surgeon for six months. Salary at the rate of £125 per annum.

Huddersfield Infirmary.—A Senior House Surgeon and a Junior House Surgeon. Salaries £80 and £60 per annum respectively with board, lodging, and washing.

Loughborough and District General Hospital and Dispensary, Loughborough.—Resident House Surgeon. Salary £100 per annum, with furnished rooms, attendance, and board.

Fulham Parish, London.—Resident Medical Superintendent of the Infirmary and Medical Officer of the Workhouse. Combined Salary at the rate of £300 per annum, with residence, fuel, lights, and washing.—Applications to the Clerk to the Guardians, 75, Fulham Palace Road, Hammersmith, W.

Royal South Hants Infirmary, Southampton.—House Surgeon. Salary, £100 per annum, with rooms, board, and washing.

Victoria University, Manchester.—External Examinership in Anatomy for three years. Applications to the Registrar before Nov. 1st.—(See advert.)

Appointments.

BARNES, J. SANDERT, M.B.C.S., L.R.C.P.Lond., Junior Medical Officer to the Borough Asylum, Portsmouth.

BROWN, E. ARCHER, M.B. Edin., M.B.C.S., L.R.C.P.Lond., Second Assistant Medical Officer to the St. Marylebone Infirmary, Notting Hill, London.

BUCHANAN, E. MCN., M.B., C.M.Glasg., F.F.P.S.Glasg., Bacteriologist by the Corporation of Glasgow.

FORSYTH, C. E., M.B., Ch.M.Aberd., Assistant Medical Officer to the County Asylum, Dorchester.

HUNGERFORD, GEOFFREY, L.R.C.P. and L.R.C.S.Irel., Assistant Medical Officer to the Wonford Hospital for the Insane, Exeter.

HUSKIS, J., M.B., C.M. Edin., Public Vaccinator and Medical Officer for the South Sefton Sanitary District of the West Derby Union.

JOYCE, R. C., M.B., C.M. Edin., Medical to the Standard Colliery, Ynyahir, South Wales.

MACLEAN, MADGE S., M.B., C.M.Glasg., House Surgeon to the Victoria Hospital for Sick Children, Hull.

MILTON, JOHN PENN, L.R.C.P.Lond., M.B.C.S., Medical Officer and Public Vaccinator for the Parishes of Penzance Civil, Penzance-in-Maldray, and Paul, Cornwall.

OWEN, E., L.R.C.P., L.R.C.S. Edin., Public Vaccinator for the District of Sefton North of the West Derby Union.

PEARCE, G. H., L.R.C.P., L.R.C.S. Edin., L.F.P.S., Medical Officer of Health by the Darton Urban District Council.

WILLIAMS, W. J., L.R.C.P. Edin., L.F.P.S.Glasg., Medical Officer to the Carnarvon Isolation Hospital.

Births.

ACHESON.—On Sept. 22nd, at St. Ronan's Road, Southsea the wife of Surgeon J. H. Acheson, R.N., of a daughter.

BATTLE.—On Sept. 18th, at Harley Street, London, W., the wife of W. H. Battle, F.R.C.S., of a son.

MACVOY.—On Sept. 19th, at 41 Buckley Road, Brondesbury, N.W., the wife of H. J. Macvoy, M.D., B.Sc.Lond., of a son.

JONES.—On Sept. 23rd, at 8 Church Terrace, Lee, S.E., the wife of George Jones, M.B., of a daughter.

Marriages.

FRENCH—DEACON.—On Sept. 18th, at Christ Church, Lancaster Gate, London, Louis Alexander French, M.B.C.S., L.R.C.P., of Emperor's Gate, to Florence Elizabeth, youngest daughter of the late Samuel Deacon, of Polebrook Hall, Northamptonshire.

FOOT—COALBANK.—On Sept. 19th, at St. Alban's Church, Teddington, Lieutenant Charles Montague Foot, R.N., youngest son of the Rev. C. N. Foot, of Teddington, to Nora, eldest daughter of Isaac Coalbank, M.B.C.S., of Teddington. No cards.

GRIFFITH—WILLIAMS.—On Sept. 19th, at St. Mary's, Lisca, Edward M. Griffith, M.D., son of the Rev. E. M. Griffith, Rector of Cloacanog, North Wales, to Muriel, daughter of the Rev. Basil Williams, M.A., Vicar of Risca, Monmouthshire.

LAYER—CONOR.—On Sept. 21st, at St. Andrew's, Ashley Place, London, S.W., Philip Guyon Layer, L.R.C.P., M.B.C.S., second son of Henry Layer, M.B.C.S., J.P., of Colchester, to Constance Mary (May), only daughter of Colonel Cecil Conor, late Comdg. 1st Batt. Duke of Wellington's Regt.

Deaths.

COLLINGWOOD.—On Sept. 23rd, at Ringwood, Hants, David Collingwood, M.D., F.R.C.S., late of Sydney, aged 41 years.

ROPE.—On Sept. 13th, at Harley Street, London, W., Henry John Rope, F.R.C.S., of St. Mary's Court, Shrewsbury, aged 51 years.

WHITE.—On Sept. 24th, at Eastbourne, Joseph White, F.R.C.S. Edin., of Southwell Gdns., S.W., late of Nottingham, aged 77 years.

Vienna Clinical Lecture.

A NEW METHOD OF ESTIMATING LITHATES IN THE URINE.

By Drs. FREUND AND TOPFER,

Directors of Pathological Chemistry in "Rudolf-Stiftung," Vienna.

[FROM OUR OWN CORRESPONDENT.]

At the laboratory class of the Rudolf-Stiftung Freund explained a handy clinical method for determining the amount of urea present in the urine, which he and his colleague, Dr. Töpfer, had practised in the laboratory during the past year with entire satisfaction.

The following method was the result of laborious experiments in accurately eliminating the total nitrogen contained in the extractives, and after a perusal of Prof. Gottlieb's method of estimating urates in the different tissues of the body.

Freund said the methods usually given in class-books for the estimation of urates were neither speedy nor accurate.

Whether we applied Bunsen's method, or the Bunsen-Pflüger analysis, there were errors to be found in our results; with the phosphate of Tungsten, boiling with phosphoric acid, or "caustic baryta-chlorbaryum" in alcoholic ether, no better results can be obtained by the precipitates. In all these different forms of analysis we have no assurance that the whole of the urates are estimated, neither can we eliminate the other cognate bodies containing nitrogen. It was strange, however, that the most insoluble salt was so little used as a test for urates in their estimation, knowing that it was an acknowledged axiom in chemistry that the most insoluble salt in the group was the most suitable for titration. In the usual textbook the detection of urates is described as giving characteristic reactions with nitric and oxalic acids which are insoluble in ether or amyl-alcohol, which is usually attributed to Brucke's observations.

With this information before them Freund and Töpfer have endeavoured to perfect a system of titration founded on the insoluble oxalate of urea in the urine, which is an important constituent in morbid conditions of the body. In health this constituent is variable, but an average has been taken of 10 to 16 grammes (154.3 to 246.8 grains) of nitrogen in 1.5 litre (0.33 gals. or 2.64 pints) in the 24 hours, or a percentage of nitrogen equalling 0.67 to 1.07; or, in other words, $N=14$ is equivalent to $C_2H_4N_2O = 30$, giving a percentage of 1.4 to 2.3, which would equal 21.5 to 34 grammes per 34 hours. But this total of nitrogen eliminated by the kidneys is not all urea ($C_2H_4N_2O$).

According to Pflüger and Bohland the average amount of nitrogen used up as urea is 86.6 per cent. of the total nitrogen eliminated, the extremes being 84 and 90.3 per cent., thus leaving 13.4 per cent. of the total nitrogen in combination with uric acid,

xanthin bases, kreatinin, hippuric acid, initial albumen, ammonia and other extractive or pigmentary substances. In febrile conditions the same authors found this relation disturbed to an average of 84.6, extremes, 81.9 to 86.6. Averages of separate authors, however, cannot be accepted as accurate standards, as they vary so widely, as for example, Bödtker, who fixes it in the healthy at 90.1 per cent. of the total nitrogen excreted. Sjöqvist records two perfectly healthy men who regularly passed 91 per cent. of the nitrogen in that form of urea. The diet has a marked influence on the elimination of urea, but in this analysts differ. According to Gumlich, living on

A mixed diet gave 85.1 urea, p.c., NH_3 4.39, remainder 10.36.

Animal diet gave 86.8 urea, p.c., NH_3 4.84, remainder 8.39.

Vegetable diet gave 80.5 urea p.c., NH_3 4.29, remainder 15.73.

Cammer obtained still more varying results with the hypobromite of soda:—

Mixed diet, 88.3 urea, 1.50 uric acid, 0.27 xanthin.

Animal diet, 93.3 urea, 1.29 uric acid, 0.10 xanthin.

Vegetable diet, 86.4 urea, 1.84 uric acid, 0.49 xanthin.

From these results we need not be surprised with the pathological variations. In two cases of phosphorus poisoning that recovered the urea was 80, NH_3 13. Two fatal: urea 55.1, NH_3 37.6, remainder 17.3. In another hepatic case with extensive degeneration of the liver the urea was 85 per cent. Atrophic cirrhosis has a reduction of $C_2H_4N_2O$, but the NH_3 is doubled, thus increasing the total amount of nitrogen eliminated although the urea is reduced. In catarrhal icterus the changes are slight. In cases of syphilis and carcinoma of the liver the urea is also found to be diminished, while the NH_3 is increased. Prott records cases of carcinoma of the liver with 77 of urea and 2.83 of uric acid; Gumlich 82.6 of urea and 5.3 NH_3 ; cirrhosis of the liver 73.8 of urea and 10.7 NH_3 .

An interesting experiment in this connection is recorded by Hahn and Nencki, who operated on healthy dogs. Their results led them to conclude that the healthy dog eliminated one part of ammonia for every 40 to 70 parts of urea. In order to determine the changes occurring in the liver an Eck fistula was made in the portal vein and hepatic artery ligatured, when the ammonia rose to one in 13 to 33 of urea. If poison were used it rose as high as 7.6 to 16.1 of urea to one of ammonia.

By destroying the liver by injecting sulphuric acid in the gall ducts the relation of ammonia to urea was little if anything altered till the terminal symptoms of coma set in. By tying the gall duct the elimination of urea and uric acid is increased. Although these relations of 86.6 per cent. of urea and four of ammonia are given as averages, Bödtker tests many with 90 or 91 per cent. of urea and 7.11

of ammonia with functional derangement of the liver or congestion, and no other morbid condition present.

Having learned from the foregoing that the urea ($\text{C}_2\text{H}_4\text{N}_2\text{O}$) eliminated in the urine during twenty-four hours averages 86.6 per cent. of the total nitrogen, the rest being ammonia (N H_3), uric acid ($\text{C}_5\text{H}_4\text{N}_4\text{O}_6$), xanthin ($\text{C}_5\text{H}_4\text{N}_4\text{O}_5$), hippuric acid ($\text{C}_9\text{H}_8\text{N}_2\text{O}_5$), kreatinin ($\text{C}_4\text{H}_7\text{N}_5\text{O}$), thiocyanic acid (C N S H), indoxyl ($\text{C}_8\text{H}_7\text{NO}$), albumen, &c. From this it would be easy to estimate the total nitrogen as is usually done, and deduct the urea. We have also seen that the N H_3 is three to four per cent. of the total nitrogen in health, but according to Hahn and Nencki the ammonia may be raised to four times this quantity by tying the hepatic artery. In this case the ammonia may be suddenly raised in the urine, while the urea may be greatly reduced, and the estimate giving still the 86.6 per cent. of urea. If the urea could be estimated absolutely this error would be averted, and a better value of secretion obtained. With this object in view Freund and Töpfer directed their attention to a method that might be both practical and accurate for daily use. For this purpose the oxalate of urea is the most reasonable to work with ($\text{C}_2\text{H}_4\text{N}_2\text{O}_2$) + $\text{C}_2\text{H}_2\text{O}_4$, which, when concentrated, throws down rhomboid crystals easily soluble in water but difficult to dissolve in ether, and by some in alcohol and amyl-alcohol. To arrive at their present knowledge several essays had to be undertaken with control experiments.

The first was performed by taking a small quantity of urine, 5 to 10 cubic centimetres, to which was added oxalic acid, gently evaporated to concentration, and finally washing the crystals with ether. It was found that the urates in the oxalic acid and ether solutions when filtered were almost negligible. It was suspected, however, that some went off with the oxalic acid in evaporation, although it must have been very small. Another hypothesis was that it formed the oxalate of soda, but the oxalate of lime gave no credence to this. Chalk was added to the ether washing, but with no better result. The experiment was next performed in cold water with the same result.

It next occurred to them that no positive error would arise if alcohol were first added to the 5 or 10 cubic centimetres of urine, and accordingly as much alcohol as urine was taken. Again, at the point of evaporation, when all the water was driven off, a little more alcohol was added to prevent a syrupy consistence. It was then rubbed up in this water-free alcoholic solution, and again evaporated with an oxalic ether solution.

This result was not so satisfactory as was anticipated, as the oxalic ether solution was prevented from acting uniformly owing to the dryness of the alcoholic solution.

It was finally arranged to add the oxalic ether solution to the alcoholic extract after partial evaporation, which had the desired effect of depositing the urine crystals in pretty white masses that were easily filtered out and washed with ether to cleanse them of all soluble matter. After many experiments testing the solution for urates, it was finally resolved that the quantity left in the solution after crystallisation and washing with ether was so small that a factor was useless; besides, it could not be calculated on the ether, as there was alcohol in the solution of crystallisation, notwithstanding the evaporation before adding the ether.

The urate rhombic prisms of oxalic acid ($\text{C}_2\text{H}_4\text{N}_2\text{O}_2$, $\text{C}_2\text{H}_2\text{O}_4$) are now dissolved in distilled water and transferred to a Kjeldahl flask, and titrated with a fourth normal solution of soda with phenol phthalein indicators. After repeated analyses by

this method, it is found that the difference between the actual drying and weighing, and trituration of the nitrogen varied between 0.012 to 0.025 per cent. of the solution giving a difference of 0.013.

The utility of the method, it may be perceived, rests on the fact that the urates alone are estimated, not the total nitrogen in the urine as is obtained in the formula $\text{C}_2\text{H}_4\text{N}_2\text{O} + (\text{Na Br O})_3 = 3 \text{ Ba Nr} + \text{CO}_2 + \text{N}_2 + 2 \text{ H}_2\text{O}$ as usually given for the estimation of the urates, but correctly speaking is an estimate of the total nitrogen present in the urines.

In order to obtain more exact data for this method a known quantity of pure urea was dissolved in a definite quantity of distilled water, and the different forms of analysis applied.

Experiment.	Amount of Urea added per cent.	Amount of Urea present.			
		Triturated with Oxalic Acid Method.		The Estimation of Nitrogen present.	
		P.c.	P.c.	P.c.	P.c.
I.	3.94 per cent.	3.89;	3.90	3.92;	3.91
II.	3.94 "	3.88;	3.89	3.90;	3.92
III.	3.94 "	3.89;	3.89	3.89;	3.89
IV.	3.94 "	3.88;	3.87	3.93;	3.92

These parallel results must convince the severest critics that this is a trustworthy method of estimating the urates. The presence of albumen or sugar in the urine does not interfere with accuracy of the results. After long practice with this method of analysis Freund and Töpfer put it forward as unassailable.

In conclusion the method modified may be briefly repeated. About 5 cubic centimetres of normal concentrated urine to which an equal quantity of a 95 per cent. of alcohol is added. (It is always better to take two similar samples as controlling each other). Place on a water bath and evaporate, rubbing well with more absolute alcohol. To the alcoholic extract 70 cc. of a pure ether oxalic solution is added and allowed to crystallise; the crystals are again washed well with ether and filtered, about 80 cc. more of ether being required. After drying filter and dissolve the crystals in a Kjeldahl flask with two drops of phenolphthalein and titrate them with a fourth normal soda solution. One cubic centimetre of this $\frac{1}{4}$ normal solution corresponds to 0.015 grammes of urea, $\text{C}_2\text{H}_4\text{N}_2\text{O}$.

OPEN-AIR TREATMENT OF CONSUMPTION.

By JOHN C. THOROWGOOD, M.D., F.R.C.P.,
Consulting Physician to the City of London Hospital for Diseases of the Chest, Victoria Park.

COINCIDENTLY with Koch's discovery of the tubercle bacillus, now recognised as the essential accompaniment of the worst cases of tuberculosis, there has come over all thinking people a great and most advantageous change in the methods of treating cases of pulmonary consumption. Many years ago the victim of phthisis could not be kept in too warm an atmosphere. The ingress of fresh air was carefully excluded from the apartment, and if change of air was made part of the treatment, the invalid was usually sent to some most enervating climate where, in a short time, stomach and liver troubles were added to complicate the disease already established in the chest.

Things now are changed indeed. The consumptive invalid is encouraged to face cold in the mountain parts of Switzerland or in Colorado and Denver City. Cough mixtures are thrown away; tonics taking their place, and, as the digestive powers in

crease, a liberal and abundant supply of good food with moderate allowance of wine is urged upon the now hopeful patient.

My own experience affords to me instances of complete recovery from phthisis due to a sojourn in the cold of Canada, and that, too, in the case of one who had frequent severe attacks of hæmoptysis, and who was liable to subacute inflammations.

Everyone cannot manage to go far away from home for a cure, and for such we have now well-planned establishments for the open-air cure. This, I need hardly say, is no new thing, but as put before invalids, it comes as a new method of treatment and so let them take it, for the idea that he is trying a "new cure" does much to help both doctor and patient. Abundant evidence is now at hand to show that the consumptive invalid must be on a dry soil. This is most essential; next the elevation should be moderate, for cutting winds will not help the treatment, though these even are not so pernicious as sudden draughts in badly arranged apartments.

An objection I have found raised to the Sanatorium plan is that it is not well to have many consumptives under one roof. I do not think this much of a drawback. Cases must of course be selected with a certain amount of discretion and experience, and then the community is likely to be a cheerful one. In the consumption hospitals of London and in the provinces the patients seem, as a rule, happy and cheerful, though few of them like the idea of quitting Ventnor or Bournemouth to return to work in smoky London.

As experience increases it will be found that some—I should say the majority—do best, as far as cure goes, from living near the sea.

Sea air contains a certain amount of saline matter, and what better inhalation can a patient have than constant small doses of chlorides of sodium and other salts deadly to the tubercle bacillus in the lungs?

A sea voyage in a sailing ship to Melbourne and back is the best way of using this saline inhalation. To undertake such a cure requires courage, and though I have been amazed to see the wonderful good that this voyage can do even in advanced consumption I would not advise any one far gone in the disease to try the ocean cure.

I have noted many cases in every walk of life who have made the Australian voyage, and my own experience is most favourable. Patients have returned home improved both in general health and in physical signs to a degree I could never have expected. Many years ago I remember how very strongly my late teacher, Dr. Walshe, urged on a young chemist in Regent Street, who had one lung well on in phthisis, to take the Melbourne voyage. Soon after his arrival we heard of him as perfectly well and growing quite fat.

So there is in the open-air treatment and its concomitants very much to cheer and encourage the tuberculous invalid, and he must not be faint-hearted, but make up his mind to do the cure thoroughly in all points.

THE FREQUENCY OF SICKROOM INFECTION IN TYPHOID FEVER. (a)

By HERBERT PECK, M.D.,

Medical Officer of Health, Chesterfield Rural District.

HE said it was generally accepted that the immediate cause of enteric fever was the bacillus typho-abdominalis of Eberth, and that invasion might take place in various ways. On the other hand, cases of the

disease were rarely traced to a definite source of infection, so that a well-known medical officer recently stated, "In probably over 80 per cent. of the reported cases of typhoid fever, the origin of the infection cannot be ascertained with any certainty." (1)

He attributed this to the fact that many cases arose under conditions in which it was impossible to say which of several causes may be to blame. This was more frequently the case in urban than in rural districts, but the number of cases in rural districts is often too small for sound deductions.

His deductions were based upon inquiries into 206 cases of typhoid fever notified to him while Medical Officer of Health of the West Lancashire Rural District during the six and a half years ending September, 1898.

Definitions.—He said: Before giving particulars concerning the class of cases with which this paper chiefly deals, I consider it advisable to define as accurately as I can the class of cases included under each heading of the following table.

Soil Infection.—This includes the cases attributed to emanations from soil containing typhoid bacilli. The experiments of Dr. Robertson (2), and Sidney Martin (3) have established the long suspected fact that typhoid bacilli can exist for prolonged periods in organically-polluted soil and even increase in number.

The nine cases ascribed to this cause occurred at intervals during a period of several years in a hamlet which had been put in a sanitary condition and provided with a public water supply, after being in an insanitary condition for many years, during which cases of typhoid fever frequently occurred. It is possible that one or more of the patients acquired the disease in another manner, but I ascribed them as I have done after careful consideration.

Drain Effluvia.—In these cases sewer gas was found to enter the houses in which the patients lived, from either broken or defective fittings.

Pollution of Watercourse.—Five of the patients under this heading lived in two houses which had nothing in common except that they lived near a ditch or watercourse into which the excreta of typhoid fever patients had been thrown. Owing to drought very little but sewage from an infected house higher up was passing down the stream.

Two other cases occurred simultaneously on two dredgers working together on a canal which was polluted with sewage at that point.

The other cases occurred in persons living on the banks of ditches or streams into which filth was surreptitiously placed, and which were sometimes very offensive.

Manure.—Enormous quantities of manure are imported into the district, but the only classes of manure to which I attributed an outbreak of typhoid fever were "black manure," which consists of human excreta mixed with ashes and cinders, and "Oldham shoddy," which consists of human excreta mixed with refuse from cotton or woollen mills.

One case was that of a child who searched among manure for marbles, and the remainder those of men who had been working among it or who had it stored near their houses.

Water.—Many cases were probably due to this cause, but only one certainly—a woman who drank water polluted with the sewage of a neighbouring town, the only one in the house who suffered at that time.

Importation.—This term includes:—(a) Where the patient had been away from home for more than fourteen days, and returned ill; (b) where the patient returned home after an absence of not less than one week, and sickened within five and fourteen days; (c) where the patient worked in a neighbouring

(a) Abstract of paper read in the Section of State Medicine, British Medical Association Meeting, Portsmouth, August, 1899.

district on premises which inquiry, made at my request by the officials of the district, showed to be insanitary.

Sickroom Infection.—I have used this term to include cases due to the ingestion of specific bacilli directly derived from excreta, and suspended in the air of the sickroom or infected part of the house, whether this took place in the act of eating or drinking, the swallowing of saliva, or in any similar way. The significance of the term will become more apparent upon a perusal of the cases ascribed to this cause.

Several Possible Causes.—This term covers those which occurred under circumstances which rendered it impossible to ascribe the origin of the disease to any one defined cause, with a reasonable degree of certainty.

No Ascertainable Cause.—This term explains itself.

Total 206

I. The patient, *æt.* 35, frequently visited her mother and sister, living in another district, when they were suffering from the disease, and fell ill as they were recovering.

II. A woman, *æt.* 29, came home from service in an early stage of the disease. Her sister, *æt.* 11, slept in the same bedroom throughout the illness, and developed the disease in a typical form about a fortnight after her recovery.

III. A gentleman came to his country house while suffering from the disease, and one of the maid-servants went down with it during his convalescence. She did not see her master during his illness, nor did she wash any infected clothing, and is believed to have contracted the disease through eating delicacies which had previously been in the sickroom.

IV. A priest, *æt.* 30, attended patients suffering from the disease, and was taken ill with typhoid fever three weeks later.

V. A woman, *æt.* 37, who had been frequently from home, developed the disease and died. Her child, *æt.* 9, frequently sat with her mother, and was taken ill the day she died. An elderly woman came from some cottages half-a-mile distant and nursed her through her illness, also washing her clothes, and developed the disease as her patient recovered. I know from personal observation that she sometimes took food in the sickroom. She returned home and was nursed by her daughter, *æt.* 25, who, notwithstanding my remonstrances, slept in the sickroom and developed the disease nine days after she had disinfecting and cleaned the house.

A child, *æt.* 4, was also taken ill, but the medical attendant did not regard her complaint as typhoid fever, though there was considerable gastrointestinal disturbance.

VI. A woman, *æt.* 30, was taken ill with typhoid fever, and was nursed by a midwife. Her nurse returned to her home in a neighbouring township at the conclusion of her illness, and developed the disease about a week later. I can only attribute her illness to her swallowing her saliva or eating in the sick room, as I know she did on at least one occasion.

Several members of the family living in the house

adjoining that of the nurse frequently visited her, and three of them were taken ill, but only one was notified as suffering from typhoid fever.

VII. A woman, *æt.* 29, drank water from a brook polluted with the sewage of a neighbouring town, and was taken ill with typhoid fever between two and three weeks later. Her husband nursed her through the illness and then developed it himself, whereupon he went to stay at the house of his father a quarter of a mile distant.

His brother, *æt.* 6, was taken ill as he got better. The house was of only one storey, and the sickroom door was often left open and so ventilated into the house.

VIII. A sailor, *æt.* 42, came home from a long voyage, and was reported the same night as suffering from typhoid fever, from which he died. His father slept in the sick room, and was taken ill with the disease nine days later. A woman, *æt.* 32, nursed them, and was taken ill between four and five weeks after the return of the first patient. She was removed to a local hospital where she died. A boy, *æt.* 7, slept in a room communicating with the sickroom of the first two patients, and developed the disease six weeks after the return of his uncle, the first patient, from sea. Fourteen days later his other uncle, *æt.* 27, who slept with him until the commencement of his illness, also went down with the complaint.

I had recently condemned the premises on which these cases occurred as unfit for human habitation, but they were carefully attended to throughout the series of cases, for which they were in no way responsible. The water supply was the same as that of a dozen other households which did not suffer from the disease. The excreta were disinfected with corrosive sublimate solution, 1 in 960, from the commencement of the outbreak, and I can only attribute the disease to the fouling of the bed linen.

IX. A young man, *æt.* 21, stripped off the wallpaper of a room in which there had been a case of typhoid fever and began to be ill twelve days later. He was reported on the sixteenth day to be suffering from typhoid fever.

X. A girl, *æt.* 8, was allowed to sleep in the same room as a patient suffering from the disease (which he probably contracted outside the district), the medical attendant saying that this was "quite safe." She was taken ill nineteen days after the first patient.

XI. A girl, *æt.* 17, slept in a room leading from the sickroom of a typhoid fever patient and began to be ill three weeks after the latter, the disease being well marked.

XII. A woman, *æt.* 26, worked on a canal boat and probably contracted the disease outside the district. Her brother, *æt.* 29, attended to her on the boat and began to be ill twenty-one days after she did.

XIII. A girl, *æt.* 7, contracted the disease and died. Her sister, *æt.* 18, came home about a week before the death and attended to her, being assisted in the task by her father. Both father and daughter contracted the disease and the latter died.

XIV. The first patient was one of two mentioned as having contracted the disease while working on canal-dredgers, and was brought home ill, but died twelve days later. His sister, *æt.* 7, was frequently in the sick room, and was taken ill with the disease twenty-two days after his return home.

XV. A girl, *æt.* 7, was "feverish" and suffered from diarrhoea, but was not seen at that time by a medical man. A brother and two sisters slept in the same bedroom, and developed the disease simultaneously about five weeks after the commencement of her illness. Their mother nursed them, and developed the disease four weeks later.

Their next-door neighbour assisted them with the

housework during the illness, and a child which she frequently brought into the sickroom developed the disease.

XVI. A person suffering from typhoid fever was frequently visited by his uncle, æt. 40, who spent many hours at his bedside. The latter lived at a house about two miles away, and took to his bed twenty-six days after his last exposure to infection.

CONCLUSIONS AND REMARKS.

The sixteen groups of cases described above include 28 which may be accepted as cases of "sickroom infection," equal to 13.5 per cent. of the cases investigated. Four other cases were probably also due to this cause, but I prefer to exclude them rather than weaken a good case by the employment of doubtful evidence. It is also probable that other cases are included under the headings "*Several Possible Causes*" and "*No Ascertainable Cause.*"

My conclusions are:—(1) That sickroom infection is more common than is supposed, and does not receive the attention it deserves; (2) That sickroom infection is much commoner in the small and often crowded houses of the poor than in the larger houses of the well-to-do.

Though it appears remarkable that so little importance should be attached by the medical profession to this mode of infection, reasons for it are not hard to find. I think the chief of them are the difficulty of excluding other possible causes, and the comparatively small number of cases met with by individual practitioners. Another is the fact that it is the practice in some general hospitals to treat typhoid fever patients in the same wards as patients suffering from other diseases. I do not consider the practice wise, for accidents may happen even in a hospital, though there is a great difference between the amount of risk incurred in a hospital, where the excreta are cremated or carefully disinfected, and the stock of linen is practically unlimited, and articles are removed as soon as soiled, and in a cottage, where the importance of the disinfection of the excreta is not understood, and the stock of linen limited, so that soiled linen is sometimes used for days and even weeks. In connection with this latter point I may say that only two of the cases detailed, viz., Nos. III. and XVI., occurred in houses with more than three bedrooms, and these did so under peculiar circumstances.

Under the conditions usually met with in small houses, opportunities are afforded for the drying of portions of the excreta of the patient, and the diffusion through the air of the sickroom of the typhoid bacilli, and possibly their spores. Those who have noticed the comparatively bulky notes illumined in a sunbeam will understand how this occurs.

Dr. Philip Boobhyer (4) found that 85.3 per cent. of the cases which occurred at Nottingham during the ten years ending 1896 happened in houses of five rooms or under, and 14.7 per cent. in larger houses. The sanitary condition of the larger houses may have been better than that of the smaller, and their occupants may have been more intelligent or docile than those of the cottages, but my own experience teaches me that this sidelight of Dr. Boobhyer's inquiry into "Endemic Typhoid Fever in Nottingham" tends to prove my contention that a larger number of cases of typhoid fever than is suspected is due to what has been called "aerial" and "direct" infection, but which I consider might be more appropriately called "sickroom infection."

OPENING OF THE MEDICAL SCHOOLS: INTRODUCTORY ADDRESSES. WINTER SESSION, 1899.

ST. GEORGE'S HOSPITAL.

MEDICINE, OLD AND NEW.

By W. HOWSHIP DICKINSON, M.D., F.R.C.P.

THE orator commenced by congratulating his listeners on having selected medicine as a calling. He contrasted the physician's objects and aims with those of the advocate and the clergyman, pointing out that medicine is wholly beneficent, at least in intention. The opponent is disease, and is always in the wrong. The advocate is bound to a side which may not be that of justice. No such partisanship directs the efforts of the physician, all rejoice in his success and agree in lamenting his failure.

After a brief review of the history of therapeutics, and the change that characterized the modern treatment of disease, the orator observed, that in recent days antipyretics have come into fashion which, if ever useful, I take leave to think are more often injurious. If Nature raises the temperature of the body, Art is invoked to lower it, as if the danger lay in the temperature rather than in the condition which caused it. No doubt a very high temperature is in itself injurious, but it is more to the purpose to say that a person has a high temperature because he is ill than that he is ill because he has a high temperature. I have known the body heat to reach 111 deg. and recovery to occur without the employment of any special means to make it less. Let us not be in haste to attack the temperature as if it constituted the whole or chief danger. I regard it not so much as a danger as a sign of danger. Antipyretic drugs are, as a rule, depressing; it may be that some, who might have survived their disease, have succumbed to the combined effects of the disease and its treatment. Increased temperature represents increased combustion, and occurs especially when there is a poison to be got rid of. I have often asked myself whether this destructive process is not also a purifying one, whereby offending matters in the body are burnt and purged away.

After an allusion to the methods of treating tuberculosis, for example, the orator called attention to the progress effected in the substitution of scientific for empirical methods, which had enabled us to recognise and isolate the essential principles of many diseases and morbid processes, and had compassed achievements, mostly in prevention, but to some extent in cure, which we ourselves must wonder at and which our forefathers would have regarded as impossible.

Passing on to the consideration of diseases due to bacilli, and how far we can prevent or control the morbid processes with which they are connected, the orator observed that three methods present themselves. (1) Killing or excluding the microbes. (2) Establishing immunity in the individual. (3) Employing antidotes in the shape of the antitoxins.

Antiseptics had done much in surgical practice to prevent infection, and if our present knowledge does not enable us to cure zymotic disease, it has provided us with means of prevention which have done much and promised more.

The great discovery of Jenner, on the one hand, and the discovery of antitoxic serum—serum made prohibitive of a disease by acting upon it with material which that disease has generated, on the other—marked steps in the evolution of medical science.

What with Jenner's fundamental discovery, remarked the orator, the super-additions which modern science has built upon it, and the new modes of creating antidotes to disease by the use of its own products, we see a wide prospect of relieving the ills of mortality, limited though it be by the prejudice of the vulgar and the subservience of politicians who value the votes of their constituents more than their lives. This brings us within sight of the "conscientious objector," though one does not see how conscience is concerned

in a matter which is not one of religion or morality, but of expediency. The conscientious objector is himself to be objected to as one who presumes without special knowledge to decide upon a question where special knowledge is required. Ignorant he necessarily is, but he is less to blame than his betters, who have endorsed his ignorance and allowed it to influence legislation. Liberty is an excellent thing, but to give liberty to spread small-pox may be thought to be carrying it too far.

The orator concluded his address with the observation that if we regard medicine as a science, if that can be called a science which is a quintessence of many, it is of all the most progressive, and it is that which of all others tends most directly to the benefit of mankind. Those are to be congratulated who have chosen this vocation, whether it be looked upon as an intellectual pursuit or as affording opportunities for doing good.

UNIVERSITY COLLEGE HOSPITAL.

By G. F. BLACKER, M.D., M.R.C.P.Lond., F.R.C.S.Eng.,
Assistant Obstetric Physician to University College Hospital, and
Obstetric Physician to the Great Northern Central Hospital.

In welcoming the new comers, he observed that their support was the more welcome seeing that it was uncertain whether the medical school of University College will continue to be associated with the college in which during all the past years its work has been done, and what is to be the exact position with regard to the new university from which they hoped so much. They would, he said, shortly be bidding adieu to the old buildings, and this carried him back to the beginnings of our hospital and the men who formed its staff in the year of its opening, 1834. The North London Hospital, as we learn from Mr. Nixon's history, practically made a beginning as the University Dispensary, 4, George Street, Euston Square. The management of the dispensary was in the hands of a committee of the proprietors of the University of London elected by the council. At a special general meeting of the council of the University of London held on September 30th, 1828, the attention of the proprietors was called to the great advantage of having a hospital for clinical instruction attached to the university, and under the control of the council. After some little delay a start was made in May, 1833, and on the 22nd of that month the foundation-stone was laid by the Duke of Somerset. In 1840, as further accommodation was urgently necessary, the south wing was completed and opened, and at the same time out-patient accommodation was provided. The north wing was built during the year 1846, giving the building its present form. The staff of the hospital at its opening was as follows:—The physicians were Elliotson, Thomson, and Carswell; the surgeons were Samuel Cooper, Liston, and Richard Quain, and the obstetric physician was Davis. The opening of the hospital in 1834 marked a most important epoch in the history of medical education. Medical teaching at that time was mainly in the hands of the private schools, anatomy was almost solely taught in them, and so, too, were many of the other subjects. At this time the system of election to the staffs of the large hospitals was a most vicious one. It was the custom for the surgeons to take private pupils or apprentices who paid them enormous fees—a thousand guineas was not an uncommon sum—on the understanding that when the time came they should be appointed to the post of house surgeon or house physician under their respective patrons. By this invidious custom many men who were most worthy of obtaining posts upon the staffs of the large hospitals entirely failed to do so, and the abuse prevailed to such an extent in the case of the two united hospitals of Guy's and St. Thomas's that nearly every member of the staff was either a relative or had been a pupil of Sir Astley Cooper. At the smaller hospitals a similar system prevailed; an appointment was obtained mainly by the expenditure of money or by intrigue. The degrading system of canvassing the whole of the governors was insisted upon, and votes were openly bought and sold; worse than this, the result of an election often

depended solely upon the amount of money the unfortunate candidates were able to lay down, since an appointment was frequently gained by the wholesale creation of faggot votes at the last moment until one or other of the candidate's resources failed him. It will ever be to the honour of our college and hospital that this pernicious system was not allowed to prevail within its walls. From the very commencement the appointments were made by selection; and personal intrigue, family influence, and monetary considerations were never permitted to influence the result. Their hospital was the first to adopt the system of throwing the resident appointments open to competition, any student of the hospital being entitled to compete if he had attended a certain number of lectures.

The lecturer then gave biographical sketches of past members of the staff, touching on their claims to fame and to the esteem of their professional descendants.

The lecturer concluded his address with the remark that he could place before them no better incentive to work than a recital of some of the memories and traditions of their school. But it would not do for them to ever rely upon the traditions of the past; it is necessary for them to build up traditions of their own. It would be their duty to see that they make a good use of the opportunities afforded to them by that magnificent building now in course of construction, and to make their work in that new building worthy of those traditions of University College and the present hospital. He pointed out to the students that as medical men they were called upon to play a two-fold role. It was their duty not alone to acquire as complete a knowledge as they could of purely professional matters, but they should seize every opportunity of improving their general education and of acquiring a knowledge of the world. Their success in life would depend as much upon the latter as upon their professional attainments. Though no doubt the competition in the medical profession is ever increasing, yet the opportunities afforded them of fitting themselves to emerge successfully from the struggle were greater now than they ever were. At the same time they must remember that more is expected of them, since the education of the general public in scientific matters is much higher now than it was a few years ago. If they will but make good use of the opportunities afforded them they would have no difficulty in acquiring a sound knowledge of medicine and surgery, but at the same time they should make it part of their education to cultivate a healthy interest in all the many details of life met with outside the profession. It is by no means certain that a man's business is the most important part of his life, says Robert Louis Stevenson in his most fascinating "Apology for Idlers." Perpetual devotion to what a man calls his business is only to be obtained by perpetual neglect of a great many other things. It is well to remember the old saying which tells us that if a man reads too hard he will have little time for thought, and Robert Hall's summary of a certain learned but dull personage, "He had so many books upon his head that they pressed too much upon his brain." He is but a poor doctor whose sole attainment is his knowledge of physic.

CHARING-CROSS HOSPITAL. THE OUTLOOK IN MEDICINE.

By DR. MITCHELL BRUCE, F.R.C.S.

The orator premised that the Outlook in Medicine as a useful art is hopeful at the present time, as evidenced by the fact that the scientific method was now being pursued in every department of it. He insisted on the importance of etiology as a branch of study, and incidentally on the importance of the role now played by bacteriology in that connection. In respect of individual susceptibility, he pointed out that we had within us a natural disposition to keep well which, if cultivated, would preserve us from evil when others who neglected the laws of healthy living were struck down around us. The body was automatically guarded against the incursion and action of injurious influences by possessing provisions for resistance which were capable of being cultivated, strengthened, and

artificially reinforced. Many of these were anatomical and physiological arrangements, which must be kept in perfect working order; but more powerful and complex, however, than these was the provision for combating destructive micro-organisms, the discovery and study of which had inaugurated a new era in medicine in respect both of prevention and treatment. The microbes of disease did not have it all their own way in the human body. From the moment of their invasion the ultimate cells of the blood and organs rose against them and produced a chemical antidote to their poisons, antitoxins to the toxins, and, by-and-by, if the patient survived sufficiently long, the antitoxins increased sufficiently to destroy the toxins, and recovery was the result. Naturally it had occurred to the pathologist to ask the physician, Why should we not hasten the formation of anti-toxic in the blood, so that an infectious disease shall terminate not after a week, but after a day? This question had been answered practically by the injection of the antitoxins of diphtheria and other diseases, which saved the lives of so many persons every year.

After gratefully acknowledging the liberality of the public to hospitals, particularly Charing Cross Hospital, Dr. Mitchell Bruce pointed out that with support of hospitals, if hospitals are properly served, goes support of scientific medicine, and indirectly the support of pure science itself. He alluded to the great strides taken in this direction in the provinces, and deplored that no similar munificence had been displayed in the metropolis. Would London ever do the same, he asked, in a concerted and successful fashion? When had we heard of an Owens or a Whitworth immortalising his name by a noble gift to the University of London? The metropolis, he observed, appeared to possess no municipal pride in this direction.

After some remarks on the way in which public opinion had been enlisted on the side of compulsory and preventive hygiene, the orator went on to observe that the position of the profession as a profession, and the work of each of the students, would be something very different from those of their predecessors. They were contracting new obligations to others, and therefore new obligations to themselves as students, as men about to enter a career involving the management of a multitude of complex and delicate social duties. Twenty years ago students learned medicine with a view to practise it as successfully and scientifically as they could; to become the trusted and faithful friends of sick persons of every rank of life who might ask their assistance; to take an honourable place in the community, wherever their lot might be cast; and to play an active and useful part in social reforms, like their neighbours, when the occasion arose. How different was the prospect before each of them now? how much greater the authority and powers they would wield when they became practitioners? how much more grave their responsibilities? how much need for increased intelligence, tact, patience, consideration, high sense of duty, and therewith the development of the faculties demanded in the conduct of public business? He then discussed how these considerations must bear upon their course of study, and showing how necessary it was to educate the public in the laws of hygiene, beginning with the young.

In connection with the present movement in support of the open-air treatment of tuberculosis, would it not presently occur to people, he asked, that if consumption can be arrested by means of fresh air it might be prevented by the free enjoyment of fresh air; and not only consumption but a host of other diseases? One of the chief benefits of the present stir in this direction would be that individual men and women would be convinced of the value of a pure atmosphere to themselves individually, and let a little fresh air and light into and through their houses.

In conclusion, he urged that they must be prepared to take part in the social life of the community, of which they, as students, would now form part; adding that there was no reason why the student should not open his mind at the same time to the elevating and refining influences of literature, of history, of modern languages, and of the fine arts, those parts of his mental equipment

which enabled a man to enter with success into the discussion and management of the affairs of his personal, domestic, and social life; which endowed him with what are known as judgment, intelligence, tact, and clear-headedness; which contributed so much to the formation of high character and sound moral principles; and which secured for him public respect and confidence.

ST. MARY'S HOSPITAL. ON SOME MOTIVES AND METHODS IN MEDICINE.

By H. G. PLIMMER, M.R.C.S., F.L.S.

The study of medicine is divided into two great divisions, the first relating to practical usefulness, the second relating to scientific investigation, and each of these divisions can be attractive to men who are entering life, according to their disposition of mind, both dispositions of mind being equally noble. It is usual to tell students that the profession of Medicine is the best and noblest of professions, but it is not in itself so. It is only as noble as you choose to make it, which is quite a different thing. To many members of our profession it remains always nothing better than a trade, and some members of it, again, are, at best, nothing better than artisans.

With regard to facts, do not attach too much importance to them in themselves, or to their acquisition. John Hunter, whose use of facts was as masterly as Darwin's, and whose methods should be a model to all of us, says, "Too much attention cannot be paid to facts, yet too many facts crowd the memory without advantage, any further than they lead us to establish principles." It is these principles we should use directly in the practice of our profession. Regarded as a mere means of gaining a living, medicine is a poor trade for an honest man, and there are many easier and better fitted for that purpose. But to those of you who would be seekers after truth, or whose aim is that of usefulness to others, it is certain that you will not be disappointed in the profession you are entering to-day.

The author adopted John Hunter's definition of medical science as "the experimental analysis of life in health and disease," and he pointed out that the object of experimental methods in pathology is to simplify its many problems. One of the greatest advances made in modern times being the recognition of the fact that disease must be studied by experiment. It has taken several centuries since Bacon's era to discard fancies and theories, and to bring the experimental method into this branch of science. Contrasting the value of the information afforded by experimental methods as compared with mere observation, he observed that simple observation certainly furnishes a certain number of valuable hints and suggestions, but nothing more, and it would be quite as senseless and impossible to try to establish a system of scientific etiology from examination of a dead body as to try to establish the principles of mechanics by looking at a broken machine.

The etiology, for instance, of those diseases only which can be reproduced at will, can be accurately regarded as known. This brings us to the logical conclusion that our ignorance of etiology must be very great, especially about those diseases which cannot be reproduced by any means at present in our power, even when the symptoms and pathological anatomy of such diseases are well known, as is true, for example, in tetanus and cancer. By the experiments which scientific medicine has undertaken, the contagium vivum of many of the most deadly diseases has been isolated, and thereby is fulfilled the first condition for guarding against such diseases: the first condition and the basis for the great ideas and principles of prophylaxis have been attained.

We are in this hospital very favourably situated with regard to investigation and experimental work, for here clinical and experimental work, when necessary, go hand in hand. In some London hospitals scientific and experimental work is discredited and not allowed; but here, thanks to the large mindedness of our staff, every

facility is placed in our hands for investigation and research; and I feel sure that this plasticity of mind, with regard to all the great problems at present before us, will bear fruit. It should stir us all, here at St. Mary's, to take every advantage of the opportunities and help given to us, and to do the best that is in us.

I know you will not misunderstand me with regard to what I have said. As one who has been in practice, I know well the great importance of clinical medicine. I know well how important it is that every symptom should be accurately studied and recorded; how important it is that every gross post-mortem appearance should be minutely recorded; and how essential it is that our powers of accurate observation should be trained to the uttermost, till they become as nearly photographic as is possible. But it seems to me that the same amount of energy expended on experimental science will give infinitely greater results, so that any of you who may feel drawn to this kind of work need not feel uncertain of reward of your work, or of finding suitable objects to work on.

The orator concluded with a touching reference to the extraordinary stimulus which Pasteur gave to scientific investigations in disease, of so pronounced a character that medicine had really been revolutionised, and he reminded them of Renan's dictum: "*La raison triomphe de la mort, et travailler pour elle, c'est travailler pour l'éternité.*"

LONDON SCHOOL OF MEDICINE FOR WOMEN.

By MRS. GARRETT ANDERSON, M.D., Dean.

SPEAKING broadly, the work in a medical school may be divided under four heads—the study of the healthy body, the study of disease, the study of all the methods for investigating or curing disease, and the art of applying these methods. The study of the problems of life and of disease is no longer a matter of learning from books and repeating from memory. The experimental method has revolutionised the teaching of physics, chemistry, physiology, and pathology. Large and costly laboratories are now absolutely necessary if the students are to keep up with what is required of them by examiners. There can be no doubt that the experimental method of teaching is the true one, whether much or little of any subject is wanted as a foundation for the scientific study of medicine.

The study of pathology, or the causes and effects of departures from health, ought, if possible, to precede work in the hospital wards. The student should know what disease is before he attempts to recognise it in individuals. All honest quackery is based upon complete ignorance of pathology; dishonest quackery on the conviction and the hope that the patient is completely ignorant of it also. In studying how to investigate the meaning of symptoms in a patient, the best rule is to look at everything and to guess at nothing. In the words of Sir Wm. Gull, "We make more mistakes by not looking than by not knowing." The organisation of the Royal Free Hospital as a teaching hospital has made great progress in the 22 years since women were admitted as students. It is a very difficult and complex business to change a hospital that has been without students into a first-class hospital school. Students want a great deal, and it is no easy matter to provide properly for them. When they are no longer students they want from their hospital the opportunity of gaining experience as practitioners. Much is being done at the Royal Free Hospital in this direction. The influence of competition is now beginning to be seriously felt by the schools that admit women, and it is an influence that will be felt more and more as time goes on.

As to the cost of a medical education people get as a rule what they pay for, neither more nor less, and if a medical student wants a great deal of the best teaching it will cost more than the minimum of teaching of a less ambitious type would. The hospital that gives resident posts to women graduates will be noticed very favourably by students. The London School of Medicine for Women is now being rebuilt. Fifteen thousand pounds has already been spent on the building, and £12,000 more

has to be spent. It is to be hoped that the work will be completed next year, and that the debt on the building will be gradually extinguished.

No apology is necessary at this time of day for the study of medicine by women. It is generally recognised now that women have exactly as much right to practise medicine and to support themselves by doing so as men have. They are doing excellent and highly skilled work in medicine proper, in surgery, and midwifery in almost all parts of the world, and so long as their work continues to be good they are sure to prosper.

Lunacy Department.

ASYLUM REPORTS.

ENGLISH ASYLUMS.

GLOUCESTER COUNTY.—The Committee call attention to the large increase in the number of patients chargeable to the county, viz.:—897 as against 826 at the close of 1897, a net increase of 71. This increase is entirely attributable to a diminished death and recovery rate, a large proportion of hopeless and incurable cases having been admitted during the year. Unhappily the same experience is widespread wherever there are asylums, and the serious result is being forced on the notice of asylum authorities that asylums are not regarded *bona fide* as asylums but as convenient receptacles for the flotsam and jetsam of humanity. The report of the Commissioners is very satisfactory, but they should distinguish between wet beds on the male side and wet beds on the female side. The Chaplain's remarks on the spiritual and moral treatment of some idiots—or, he should rather have said, imbeciles, are forcible and sympathetic.

DORSET COUNTY.—This report is voluminous, and in some respects interesting. Dr. McDonald expresses his views at some length, and warmly commends the open door system, which he has introduced with, evidently, satisfactory results. The percentage of admissions to the numbers resident is not high, and the recovery rate is lower. Dr. McDonald says, "There is much force in the statement put forward a few years ago by an eminent physiologist, 'that the race is degenerating,' and there would seem to be a curious link of connection between this so called degeneration, and the practically proved falling off in the recovery rate in the public asylums of this country. While there is food for thought and suggestion in this statement, one is compelled to ask does it not also beg the question? Is it the truth or only half the truth? The race has probably been degenerating in the estimation of its wise men for centuries. The level of intelligence and education has been raised, but this serves all the more to mark contrasts which in pre-education days were less noticeable. If scrofula and phthisis are signs of degeneracy surely *pro tanto* these signs are diminished to-day compared with thirty years ago. Their relation to idiocy and mental disease has been pretty well established by Ireland and Clouston. Old age has as much to do with diminished recovery percentages as anything. The fifth commandment is not respected as it used to be. The cost of clothing is very low. The dietary is varied, which is commendable, but two courses each day at dinner would give more variety still, and meet the individual cravings of so many patients more fully. The report altogether is full of detail, and gives evidence of the superintendent's desire to be up to date in all departments of the management.

MIDDLESEX COUNTY.—The report of the Visiting Committee is rather a long one, but of no very special interest. It has been found necessary to raise the charge for maintenance from 11s to 11s. 6d. a week. There is here as elsewhere necessity for increased accommodation. More than 10 per cent. of the admissions were senile cases, 5 per cent. were general paralytics, and 7.5 per cent. were epileptics. The death-rate from phthisis is somewhat large. The Commissioners speak in high terms of praise with regard to the condition of the wards and

dormitories, and the good order and tranquil behaviour of the majority of the patients.

WEST SUSSEX, CHICHESTER.—The second annual report gives abundant evidence of push, energy and enterprise in the management, and the results in so short a time seem to be very satisfactory. Already, however, further accommodation is required and plans for new wards for 300 patients are about to be submitted to the Commissioners in Lunacy. Influenza has visited the asylum with the usual experience that the officers and staff have been more severely attacked than the patients. Dr. Kidd mentions a physical cause of insanity, especially of melancholia, viz., defective and decayed teeth. He observes "it is remarkable how frequently melancholics are found to have thoroughly bad teeth, and it is no wonder that indigestion, loss of appetite, refusal of food, and a train of other symptoms obtain." He therefore recommends the engaging of a visiting dentist. The pathological laboratory is reported to have been well fitted out and put into good working order by the medical officers, who have devoted a great deal of time and attention to this work. Like many other superintendents, Dr. Kidd would like to see the opprobrious word *asylum* dropped, and *hospital* substituted.

CARMARTHEN.—Here, as elsewhere, there is evidence that the Commissioners make a point of reducing the number of wet beds. "In 9 cases out of 628, or 1.4 per cent., were patients' beds wetted last night." This is a question agitating some Commissioners and superintendents over much. There are extremes with all hobbies. The record stated is a very fair one. Dr. Goodall is evidently trying in many ways—medical and administrative, to bring the asylum here up to the standard of modern ideas, and he has had many difficulties in taking over the command of an old asylum.

DERBY BOROUGH ASYLUM.—The Commissioners' reports do not appear this time. This is unusual. Dr. Macphail has nothing of special interest to report unless it be his summary of ten years' results. Influenza is now coming to be recognised as a cause of insanity. In ten years there have been 88 cases, or 8.9 per cent. Dr. Macphail observes regarding the alleged increase of insanity:—"I am of opinion that the only true test of the increase or decrease of insanity in a district, is to take the cases occurring for the first time in each year, to exclude all readmissions, and to compare with the population over a series of years. This has been done in the case of the borough, and a tabular statement shows that there has been no increased ratio of new cases."

THE LAWN, LINCOLN.—Structural and other improvements continue to be made in this well-known hospital home for private patients. There is a persistent movement in the direction of social and administrative novelties and changes calculated to make the Lawn more attractive to its residents. The average number of patients is in excess of the previous year. "The committee have felt themselves justified in raising the ordinary weekly payment to 40s., but while this low rate might suggest to outsiders the idea that the comforts and equipments of the Lawn are not first-class, the Committee desire to emphasise their contention that in no institution in the kingdom where the mentally afflicted are provided for can better surroundings be secured, and the percentage of recoveries and reliefs testifies to the advantages secured by a term of residence at this institution for those requiring treatment." We have quoted this passage, because we believe it is no overstatement of fact. Dr. Russell's report gives an idea of the freedom enjoyed by Lawn patients. "As in former years many have had leave of absence to spend various periods with their friends or at health resorts." A party of ladies and gentlemen, under the charge of the assistant Medical Officer, spent three weeks at St. Leonards. The annual ball, as usual, was a fancy dress affair.

SCOTCH ASYLUMS.

ROXBURGH, BERWICK, AND SELKIRK.—This, as usual, is a careful production, and the statistics and financial statement are full of detail. Dr. Carlyle Johnstone is evidently following closely on the heels of the latest asylum developments in Scotland, though he is not one to accept blindly new views, however attractive they

may appear. The night service is improved. A new female hospital has been erected, and it will probably illustrate still further the matured views of asylum men regarding the requirements of an asylum hospital.

ABERDEEN ROYAL.—The reports are very satisfactory, and Dr. Reid enters fully into a description of changes and extensions which will materially increase the efficiency of the asylum management. A most amicable settlement has been arranged between the Parish Council of Aberdeen and the directors of the Royal Asylum, whereby the former becomes a Lunacy District Board for the city of Aberdeen, and will undertake to build a new asylum to accommodate the pauper lunatics chargeable to the city, these being meanwhile provided for in the Aberdeen Royal Asylum.

DUNDEE ROYAL.—The financial position of this asylum seems to be steadily improving. The following extract from Dr. Rorie's report is worthy of quotation as coming from the pen of Miss Honnor Morten, having appeared in the *Evening Telegraph*:—"There is one word to be said to the would-be nurses who storm our hospital portals. Why not become asylum nurses? There is no disease that requires more careful and skilful nursing than mental disease. The era of trained nursing in asylums has dawned, and men and women endowed with sympathy for suffering, and with good health and intellectual gifts may find a new vocation in tendance on the insane. . . . The work is among the highest to which it is possible to put the hand, but it calls for some self-sacrifice. Surely, if we take the degrees of comparison, it is well to be a 'home' nurse, and capable of caring for one's relations; it is better to be a 'hospital' nurse, and equal to attending on the stranger who is physically ill; but it is best to be an 'asylum' nurse, and minister to the mind diseased." It seems absurd that the medical report should be cut down, at the discretion of the Committee, for publication, but so it is.

GLASGOW DISTRICT, WOODSIDE.—This, in many respects, is a thoroughly business-like report. The Brabazon scheme of occupation, of a varied character, for patients, who would otherwise be left in an idle, uninterested condition, is here in operation. It is said to afford much interesting and profitable employment to a number of suitable patients. A committee of about 12 ladies, chiefly from Lenzie, attend at the institution for two hours every Friday, and teach ten male and thirty-five female patients the various occupations introduced by the Brabazon Society. The kinds of work taught consist of Smyrna rug making, painting on cards and match-boxes, making paper flowers, lamp shades, &c. Dr. Blair includes in his report a special pathological report by Dr. Marr, the senior assistant. Dr. Marr considers that asylum pathology needs a man for this alone. He is right.

MONTROSE ROYAL.—Dr. Havelock's report covers many topics, general statistics, night supervision, regarding which he has some sensible remarks, sewage disposal—he favours bacteria beds, which scientifically is the best idea—the opening of Carnegie House, an extension of the private asylum, named after Mrs. Susan Carnegie, who founded the Montrose Asylum in 1781, erection of new villas, &c.

LANARK COUNTY.—Dr. Campbell Clark, in a lengthy report, refers to several matters of interest. He has now focussed to a point the possibilities of spleen extract in the treatment of mental cases. Its chief use is in the treatment of adolescents, especially males. He makes appropriate reference to the decease of two old stagers, and points out the "fact not sufficiently realised by the general public, that an insane person may have a social and industrial value, as great as an average sane person of the same class. There are men and women patients living obscure lives in asylums, of whom it may as truthfully be said 'well done, thou good and faithful servant' as of workers outside." The Commissioners specially commend the night supervision, and the industrial occupation of the patients. The asylum now has accommodation for 950 patients, and private patients are received from the district and from beyond it at very low rates of board.

IRISH ASYLUMS.

LONDONDERY DISTRICT.—Apart from overcrowding the Commissioner regards the condition and management of the asylum as most satisfactory. The medical clerical work is well done, and the attendants are carefully trained. Dr. Hetherington reports 10 deaths out of 44 as caused by consumption, "a disease," he observes, "to which the insane are particularly liable." True, under certain conditions, and one of these is overcrowding. In Table I, we find the following statement: "Limits of Accommodation (Dormitory), 166 (male), 178 (female); total, 344. Remaining in asylum December 31st, 1898, males, 243, females, 223; total, 466. This tells its own tale, and we are sure that Dr. Hetherington is fully alive to the evils attending it. The cases of escape and accident are very few considering the risks from overcrowding. Speaking of the good results the Commissioner refers to the overcrowding as apt to be lost sight of in view of these results. One dormitory according to regulation scale should have 36 patients. It actually accommodates 60. In the outside corridor 20 patients sleep at night. "These figures," quoting from the inspector "are given because some persons may be deceived by the favourable results obtained in the management of the institution. The congested condition of the asylum renders it a hot-bed favourable to the rapid and dangerous development of zymotic disease which may at any time be introduced."

DOWNS DISTRICT.—Dr. Nolan remarks: "Emigration of the young and wage-earning has been stated to be a contributing factor in the increased number of admissions of senile cases to the public asylums. It is worthy of note that in the Report of the State Commissioners in Lunacy for New York no less than 35.5 per cent. of the insane in the asylums of that State were born in Ireland. It would seem as if the conditions which necessitated emigration were potent causes of insanity, and it is possible that if they had remained at home some of those who compose this 35 per cent. would have increased the home asylums population." Here we are dealing with unknown quantities and unknown factors, and must reserve opinion. It is more than likely that the first part of the foregoing quotation contains a sound conclusion. The disease most prevalent among the patients was consumption, which caused no less than 39.6 per cent. of the deaths, and here there is no charge of overcrowding by the Visiting Inspector. The conditions are probably those which at one time made the Inverness Asylum a hotbed of phthisis, viz., insanitary, ill-ventilated homes, and insufficient food of physiological quality. Dr. Nolan has done his best under the circumstances by adopting the latest views in his attempts to stamp out, or at least reduce, the ravages of the disease. Antiseptics, open-air treatment, the testing of the milk supply, have all been resorted to.

CORK DISTRICT.—There is, and has been for some time, considerable overcrowding, and steps are in contemplation for some relief to this state of matters. Dr. Woods labours under serious disadvantages. Much has been done already to bring the administration up to modern requirements, but he has to deal with conditions which have been in existence for years, and which are growing, and paralysing as they grow. The site of the asylum, though from the æsthetic point of view an ideal one, is a troublesome one for extension owing to elevation. Dr. Woods now repeats the hope expressed in 1895, "that special provision would be made for the treatment of acute and recent cases; and the more I have since thought on this subject, the more convinced I am of the great want of means at our disposal for their proper treatment. No part of the existing building can, I think, be fully adapted for this purpose. We would require a hospital, in the truest sense of the word, with at least 100 beds for each side of the house." In the management of such an institution there must be many anxieties not dreamed of in a modern, uncrowded asylum, and the complimentary remarks of Sir George O'Farrell are well deserved.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, October 1st, 1899.

TREATMENT OF DYSENTERY.

AMONG the substances employed in rectal injections against dysentery nitrate of silver takes the first rank, white permanganate of potash is but rarely used. Yet this last agent, according to Dr. Gastinel, constitutes a remedy of considerable value. By experiments he has made he found that enemata of permanganate of potash eased better than morphia all the painful phenomena of dysentery, arrested the alvine evacuations, and effected a rapid cure, especially when they were associated with a large dose of calomel.

His treatment consists in administering at the outset an enema composed of ten ounces of a solution of permanganate of potash (1—1,000), to which is added an equal quantity of water sufficiently hot to raise the mixture to 112 degs. F. The patient lies on his left side for the first part of the enema, on his back for the second, and on his right side for the remaining third, and retains the injected liquid one or two minutes. If the visit is made in the evening no more is done. The following morning a second enema is given, followed in a few hours by the ingestion of 15 grs. of calomel. If the patient is seen for the first time in the morning an enema is ordered at once, and when ease has been procured, that is to say at the end of an hour, the calomel is given.

These enemata are repeated generally every twelve hours, and as the character of the excretions has been modified, only one is given daily, and finally only every two or three days; while at the same time the strength of the solution is diminished. The enemata are somewhat painful, but bearable, the pain not exceeding half an hour; while it is followed by a considerable relief of all the symptoms.

In children M. Gastinel employs the same treatment, but naturally the strength of the solution is much weaker (0.2 per cent.), while the dose of calomel is in proportion to the age.

INFANTILE ECZEMA.

According to Professor Marfan, of the Hôpital des Enfants Malades, infantile eczema is due to dyspepsia. The malady exists principally on the face and on the head, extending to different parts of the body, only after having occupied these regions. It commences in the third or fourth month, and, if left to itself, disappears only after weaning. This eczema, says M. Marfan, affects sometimes a special form, the moisture disappears, and the affection thereby merits the name of dry eczema but this transformation seems to take place especially when the general condition is modified, when, for instance, the child who had been fat seems to waste away. What constitutes the real danger of infantile eczema is that frequently the surface of the disease becomes infected and produces divers complications, and in particular impetigo; sometimes broncho-pneumonia supervenes.

The cause of this eczema resides generally in overfeeding provoking digestive troubles. Consequently it is of paramount importance to regulate the regime. Once a fortnight the child, if over six months, should be put on water diet up to noon and every half-hour one of

the following powders given: Calomel $\frac{1}{4}$ gr., sugar \times grs., divide into four powders. These doses are extremely small, but calomel should never be given to children under three months, and later, the above dose should not be exceeded, which will always be found sufficient for the purpose, and never provokes that dysentery so often witnessed in infants. As local treatment, picric acid might be employed in solution (1 per cent). Later on zinc ointment will be beneficial. But this local treatment, concludes M. Marfan, will be of no account if the *regime* is not regulated, both as to the quantity of milk to be given, and to the precise hours the child should take it.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, September 30th, 1899.

At the Free Society of Surgeons, Hr. König introduced the subject of

CHILD TUBERCULOSIS,

with special regard to treatment of older persons. He said that although in childhood generally conservative treatment did as well as resection, the conditions of the knee-joint were particularly unfavourable. In the capsular, as well as in the osteal form of disease, deposits of fibrine became organised, encapsulations took place in the joint, by which several independent compartments were formed, so that when an injection of iodoform or the like was made, only a portion of the diseased part came into contact with the medicament.

In spite of all exertion, therefore, occasionally the disease made progress, and nothing remained but to resect. In older people the condition was essentially the same; here such a knee was occasionally seen to heal, but a long time was required for it; two years was not reckoned high. These patients were accustomed to go from one hospital to another, and when one had treated them for a year or so with injections, firm bandaging, stasis, &c., without arriving at any desired result, the duty came upon one to set them on their feet again, so that they could do without further hospital treatment. The speaker resected in people who were 70 years old and more, age was no reason for abstaining from it. He even resected phthisical patients, so long as their condition allowed it. If large abscesses were present these were widely opened and treated openly. In a patient operated on a few weeks previously, on opening the joint the speaker only found a quite small collection of matter in the meniscus; from here a passage opened to the patella, in which there was extensive infiltrating tuberculosis. It was impossible to locate the collection before operation, even the Röntgen rays failed.

Hr. V. Bergmann also resected early in older people, but he remembered from his Würzburg days that he did not always succeed, and once had to amputate. In the 4½ years that he was there he amputated at the thigh 98 times for tuberculosis. In the case of children he considered it advisable to be as conservative as possible, on the one hand on account of the disturbance of nutrition, and on the other hand on account of the contractions that followed early operation, for this latter reason even arthrectomy was to be feared.

Hr. Bennecke read a paper on

OPERATION IN BASEDOW'S DISEASE.

Among the 25 strumectomies that had been carried out in the Charité during the last 3½ years, partial extirpation of the thyroid was performed three times for Basedow's disease. The patient died of collapse, and the other two were then shown. He was of König's opinion that the symptoms of Basedow's disease were set up by an intoxication in consequence of morbid excretion of the thyroid.

The first of the two patients shown was 17 years old, and had been operated on 2½ years. She had then a large goitre, exophthalmos, vascular murmurs, pronounced palpitation, tremor, a pulse 120 to 140. At the operation, the trachea was seen to have become very membranous. A few hours after the operation a severe attack of dyspnoea came on, it was caused by after hæmorrhage, and the coagulated blood had compressed the softened windpipe. After removal of the clots the breathing was restored and healing of the wound took place without further disturbance.

The effect of the operation was decidedly favourable, the exophthalmos and the tremor disappeared, slight attack of dyspnoea and tachycardia indeed came on at intervals, but much more rarely and with less violence than before, so that the patient was able to follow her employment, which entailed a daily work of eleven hours.

The second case was that of a woman, æt. 27. On her admission into the Charité in May, she was suffering from uncommon nervous excitability, so that she could not lie still a moment, but threw herself about. There was extreme exophthalmos, moderate goitre, free breathing, and a pulse between 120 and 160 per minute.

The immediate result of the operation was the cessation of the nervous unrest, the patient lay quietly in bed. A week after the exophthalmos began to recede, continued to improve for several weeks, and then remained in the state it had then reached. The pulse soon after the operation was between 70 and 90; it was now about 100. The general condition had improved a good deal, but there was still some palpitation. In one case examined microscopically there was slight colloid degeneration. The follicles were mostly lined with a single layer of epithelium and empty.

Hr. Wolff had never seen a cure after operation for Basedow's disease, but considerable improvement, but in the first case shown it appeared to have taken place. Hr. Hahn said that the milder cases of Basedow offered the best chances for operation. In 80 strumectomies he had operated five times for Basedow's disease, and in one case certainly with complete recovery.

Hr. Doebellin reported on

ELEVEN CASES OF INJURY TO THE EXTENSOR APPARATUS OF THE KNEE

that had been treated in the Charité since 1896. Ten were cases of complicated fracture of the patella, most of them came under treatment at once, and in all cases sutures were applied openly. The results were extraordinarily satisfactory in all. The same gentleman showed a woman who, in 1893, was operated on for

PHLEGMONOUS HERNIA, THE CONTENTS OF WHICH WERE BLADDER WALL.

In 1898 a protrusion had been observed in the old cicatrix for some time from which a warm fluid trickled. She was admitted into the Charité, and three hours

after the commencement of the symptoms it was seen that the thin bladder wall had perforated into the cicatrix, and that about 30 ctm. of small intestine had become prolapsed. These after careful cleansing with physiological saline solution were replaced, and recovery was uninterrupted, although a large colony of *staphylococcus aureus* grew afterwards upon the agar-plates that had been pressed upon the prolapsed intestine before their replacement. The cicatrix had again become thin, but the patient would not agree to any further operation.

Hr. Franke showed a man with

RUPTURED URETHRA

in consequence of fracture of the pelvis. Urethrotomy was performed, and the urethra was found torn through its whole circumference. The proximal end which lay about 8 cm. from the distal, could not be drawn down to allow of the two ends being united by suture. The bladder was therefore drained through the perineum; later on the tube was withdrawn, and the wound healed by granulation.

There was now no fistula, the whole of the urine passing by the natural orifice, and a bougie could be easily passed along the whole of the urethra, and as this could be done without drawing any blood, it showed that the whole tract was properly covered with epithelium.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, September 30th, 1899.

CINNAMIC ACID AND TUBERCULOSIS.

FOR some time past cinnamic acid has been used in the wards of Prof. Stoffella in cases of tuberculosis with considerable advantage, and in order to bring this form of treatment before the profession at the very earliest date, the professor undertook to write an article on the subject for one of the Vienna journals.

This new drug was held out as a specific in the cure of tuberculosis according to the records given by his assistant, Dr. Hoff. During the following week a letter from Feodor Schmey, of Upper Silesia, appeared in the same journal disclaiming Stoffella as the clinical discoverer of this drug, and referring him to papers written on the subject a year since. From these records it seems that cinnamic acid has been used in the treatment of consumption for a very long time, and has been administered in the form of "Peru-Cognac," which contains five grammes of cinnamic acid in a litre, or seven grains to the ounce.

To-day Stoffella humbly apologises, but repeats his perfect confidence in the results obtained from his clinical observation.

INFARCTS IN THE LIVER.

Professor Chiari has so frequently met with infarcts in the liver that he now pauses to ask the reason why, as they seem to him to be principally due to a mechanical effect produced in the vena port, and the hepatica artery. These conditions he divides into sources:—(1) the closing and contracting of a large branch of the vena port accompanied with feeble action of the left ventricle and a congested state of the venous system of the body which would produce a congestive hyperæmic centre, or the so-called atrophic infarct, also known as

Zahn's "red infarct." In its description it cannot be differentiated from the common congestion usually met with. This form develops rapidly and may remain stationary for a long time, ultimately producing induration like other congestions of the liver, or it may recede and disappear altogether. Closure of the interlobular branches will not produce analogous hyperæmia, but tying or thrombotic closure of the trunk of the vena portæ will produce the same cyanotic atrophy and induration of the whole liver. Chiari describes 17 cases he has recently investigated, all occurring from hyperæmic congestion, the result of occlusion of the vena portæ; 15 of these had the characteristic "atrophic red infarct." In all, the heart's action was feeble during life. In none were the branches of the vena portæ closed.

The second class of cases is due to closure of the smaller interlobular branches of the vena portæ, with multiple necrotic centres in the liver with or without hæmorrhagic centres, or anæmic or hæmorrhagic infarcts. He recorded a number of cases under this head occurring from emboli and thrombosis of the smaller interlobular branches whose clinical history all point to eclampsia puerperalis before death. Schmotely concluded that this eclampsia was due to a toxin produced by the coagulation of the blood in the liver.

The third class is due to the alteration in the liver cells and neighbouring structures, with necrosis of the vascular tissue producing anæmia and hæmorrhagic infarcts in the liver and closing the smaller branches of the arteria hepatica. This form of infarct is evidently due to the closing of the vascular system and arteria hepatica propria with ultimate necrosis of the liver. He illustrated this class by appropriate examples.

CARDIAC CHANGES IN CHLOROSIS.

Gautier records 22 cases of chlorosis in whom 20 of them had all the dimensions of the heart increased, viz., enlargement of the cavity, extension of area, and hypertrophy of the cardiac muscle.

In a large number of the cases these increased dimensions and the chlorotic pallor receded after a short course of treatment. In discussing the cause of the dilatation and hypertrophy Gautier attributed the entire blame to the reduced functional action of the cardiac muscle which disabled it from fulfilling its proper function in the inoculation.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

STACKE'S OPERATION FOR SUPPURATION IN THE MASTOID ANTRUM.—MR. CARLESS operated on a woman, æt 28, who had been suffering from a discharge from the right ear for eight weeks. The cause of the otorrhœa was not very obvious; the initial attack was acute, and perforation must have occurred within a few days. On admission, the discharge from the ear was not very profuse, but the patient had the evidences of mastoid suppuration, which had been evident for about a week; the temperature ranged about 100 degs., there was some headache, and the tissues lying over the mastoid process were congested, pulpy, and œdematous. The right disc was a little hazy, the patient was occasionally sick, and

seemed a little dull. Dr. Pritchard had seen the case, and agreed that it was one for immediate operation. The patient having been anæsthetised an incision was made behind the ear immediately posterior to the crease of skin at the base of the auricle; the tissues were thick and infiltrated, but there was no pus superficial to the bone. The auricle was stripped up and drawn forward so as to expose the posterior margin of the meatus and the supermeatal spine. A triangular hole was now cut into the bone by a small chisel about a quarter of an inch broad immediately below the spine, and at the first stroke of the mallet the chisel entered the antrum, the external wall of which was not more than a line in thickness, and pus escaped at once. The opening in the outer wall of the antrum was enlarged by cutting pliers, sharp spoon, and gouge, and the limits of the cavity were defined by the probe. The whole of the outer wall of the posterior part of this cavity was removed, and it was found that there was no connection with the lower mastoid cells. The passage into the attic was then carefully defined with a probe, and the bridge of bone lying over this was removed as far as the bony meatus, so that the tympanic cavity and the antrum should be freely opened superficially. Both these cavities were well curetted, and all granulation tissue removed therefrom. The cartilaginous meatus was separated from its posterior attachments, and its deepest portion incised in a T-shaped manner, the corners at the base of the T being cut away with scissors, the cavity thus formed was well flushed with 1 in 60 carbolic lotion, and packed tightly through the meatus with iodoform gauze. The auricle was then replaced and the incision closed with stitches. Mr. Carless said that this was by far the most satisfactory plan of dealing with suppurated mastoiditis; by its means the antrum and tympanic cavity could be thoroughly curetted and well drained through the meatus, which was enlarged for the purpose, all the dressings being subsequently conducted through that passage. It was also advantageous from the cosmetic standpoint since the scar was hidden behind the ear, and the wound usually healed by first intention. The greatest care had to be exercised in order to avoid wounding the facial nerve, especially when cutting through the narrow passage leading to the attic. It was, he thought, always advisable in these cases to keep a probe in the passage, and never to cut behind it. The anæsthetist should also be instructed to carefully watch the patient's face for any sign of twitching as indicating that the nerve had been touched.

GREAT NORTHERN HOSPITAL.

DOUBLE OVARIOTOMY.—MR. PRYTON BEALE operated on a woman, æt about 30, who had been admitted with a very large abdominal tumour of three months' duration. The only history obtainable was that the abdomen had gradually and steadily enlarged, with amenorrhœa, for the last two months. On admission, the abdomen was so tense that respiration was extremely difficult, and an immediate operation was deemed necessary. The abdomen was therefore opened in the middle line, and a large left ovarian cyst immediately presented. This cyst was about thirteen inches in diameter, and seemed to completely fill the abdomen. Some of the fluid was withdrawn, and the cyst pulled freely

out of the wound; it was then seen that there were several smaller cysts springing from the same ovary, and the ovary, together with about one inch of the Fallopian tube, was removed. It was then found that the right ovary was also cystic, consisting of one cyst about the size of a fetal head, together with two smaller ones. The same course was adopted with these. On examining the ovaries after removal no trace of any new growth could be seen in connection with them or with the cysts. Unfortunately they were not examined by the pathologist. Mr. Beale said that owing to the patient's condition he did not feel justified in attempting to shell out the cysts; moreover, there appeared to be very little ovarian tissue present, and under these circumstances he deemed it advisable to remove both ovaries and their tubes, which were firmly adherent to the smaller cyst. Prior to the operation the abdomen was so tense that no physical signs of fluid contained within the cyst wall were obtainable; in fact, the only thing which could be ascertained for a certainty was that the mass was unconnected with the uterus. The abdomen was closed in the usual way without drainage.

The patient made an uninterrupted recovery, and left the hospital in three weeks after the operation in good health.

It is interesting to record that this patient was re-admitted three months later suffering from numerous solid nodular tumours in the abdominal cavity and scattered throughout the abdominal parietes, including many in the skin. She was suffering great abdominal pain, and had great difficulty in passing water. On examining the bladder with the hand the organ was found to be nearly filled by a hard nodular mass. Per vaginam the vagina and uterus were both freely involved in a new nodular growth. Per rectum Douglas's pouch was filled with the same growth, and the walls of the rectum also. An exploratory laparotomy was performed, and it was then found that the whole of the mesentery was the seat of what appeared to be multiple sarcomata, the whole of the parietal peritoneum was likewise studded, together with the bladder, uterus, kidneys, liver, and spleen. The patient died about a week subsequently, and the growths were found on microscopical examination to consist chiefly of myxosarcoma. Mr. Beale afterwards said this case showed how very important it was not to lose sight of cases which had undergone ovariectomy. It was only by accident that the woman presented herself at the hospital a second time, for she had been admitted to another institution and transferred to the Great Northern when it was found that a previous operation had been performed there. The case was of interest, because at the first operation there was no trace whatever of any new growth in any of those parts found subsequently to be affected, nor were any of the cyst contents permitted to escape into the abdominal cavity, and, seeing that the whole of each ovary was removed, it must be assumed that the malignant growth started in the peritoneum, and then spread to the various viscera. He laid stress on the fact that at the first operation he had carefully examined all the abdominal viscera, as he said that it was most important that this should always be carried out as a matter of routine, especially in cases of ovarian disease.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 4, 1899.

THE LEICESTER GUARDIANS *VERSUS* THE LOCAL GOVERNMENT BOARD.

THE crop of troubles sown by Mr. Chaplin's revolutionary Vaccination Act is springing up with remarkable quickness and vigour. It is now two years since that most retrograde of measures was indelibly stamped upon the archives of Mr. Balfour's administration. The reasons of the concession to the clamours of a noisy section of faddists was obviously political, that is to say, with a view to ingratiate popular prejudice, and thereby to catch votes at future parliamentary elections. At the time when the Bill was before the House, we ventured to predict that so far from conciliating the anti-vaccinationists, the proposed measure would simply encourage them to demand an ell for every inch they had been granted. That expectation has been amply fulfilled by the subsequent course of events, which has brought about that most undesirable of all constitutional maladies, to wit, a direct conflict between local authorities and the Local Government Board. Half-a-dozen boards in different parts of the United Kingdom are up in arms because Mr. Chaplin, in order to keep any semblance of control over the unvaccinated in anti-vaccinationist districts, has been obliged to take the extreme step of asserting the vaccination officer's independence of his own local authority, so that all prosecutions are to be undertaken under the ægis of the Central body at Whitehall, and independently of guardians on the spot. This state of affairs is certain to be resented by all Englishmen, who have always asserted the powers and rights of the purse. Those who pay the vaccination officer, they

maintain, have the right to direct his actions in so important a matter as the undertaking of legal proceedings. That position is made possible only by the tacit admission contained in Mr. Balfour's Act that the doctrine of conscientious objection to vaccination is sound and can be maintained by the individual at all hazards to the welfare of the community. At any rate, the dissenting boards of guardians have refused to engage or to pay a vaccination officer who is not under their complete control. Leicester, which has always been a stronghold of the anti-vaccinationists, has defied the repeated directions and warnings of the Local Government Board. A mandamus has now been served on the Leicester Guardians, and if, as appears likely to be the case, they prove obstinate, before Christmas they will be lodged in gaol. A greater triumph than the threatened martyrdom could not be imagined for the Anti-vaccinationists; but it is to be hoped that the close of the nineteenth century will not be destined to witness so undignified a proceeding. At the same time we profess no feeling of sympathy with Mr. Chaplin in his present troubles. Small-pox, before the introduction of vaccination, caused a mortality of 7 to 9 per cent. of persons buried in London during the seventeenth and eighteenth centuries, a mortality that rose in epidemic years to 15 or even 18 per cent. Contrast that terrible state of affairs with the fact that since 1885 London has been almost immune from the ravages of that loathsome malady. This improvement, in the opinion of most modern authorities in preventive medicine, was in the main due to compulsory vaccination, but it is this beneficent instrument that has been deliberately pithed and undermined by Mr. Chaplin's weak-kneed attempts at statesmanship. The need of an adequate representation of the medical profession in both Houses of Parliament was never more apparent than in the history of this last Vaccination Act. Nemesis, however, has followed hard on the heels of legislation. A stand-up fight is taking place between the local authorities and the Central Government, and has upset the great guiding principle of conciliation that has become a first law in national administration. The anti-vaccinationists are greedy for fresh concessions, and are eagerly clutching at the crown of martyrdom now dangled before them by Mr. Chaplin. The Government that hoped to catch the votes of dissentients from vaccination are likely to rouse their bitterest opposition, for gratitude is as little known to the faddist as reason. Lastly, it remains to be seen what the fullness of time will bring forth with regard to the disease around which so much social and legislative conflict has been waged. If the anticipations of some of our sanitary experts be correct the future outlook is not free from grave anxiety. There are many matters of preventive medicine that press for treatment at the hands of Government. If, however, the administration that passed their Vaccination Bill in the teeth of universal scientific condemnation are inclined to push that disastrous policy, it is to be

hoped that they will be turned from the error of their ways and in future will confine their energies to class legislation and to a spirited foreign policy. The voice of science is the voice of truth, and cannot be disregarded by any government without the certainty of near or remote disaster. It is to be hoped that one day a large portion of the treasure now spent by Great Britain in acquiring and protecting foreign countries may be spent upon preventive measures that affect so deeply the general welfare of ourselves and our fellow countrymen at home.

A PROCTOLOGIST'S VIEWS ON CONSTIPATION.

THE average physician usually views constipation, so to speak, from the mouth, and treats it accordingly. In a recent number of the *New York Medical News*, Dr. A. B. Cooke deals with the subject from another point of view, that of the proctologist, one of the latest additions to the category of specialists. It is necessary, to begin with, to distinguish clearly between constipation and mere costiveness. Neither hard stools nor dry stools, nor other kinds of stools, he tells us, constitute constipation, for these expressions are merely descriptive of physical properties, and costiveness embraces them all. Correctly speaking, constipation is the condition of which costiveness is merely a symptom. Costiveness adds the author, is not necessarily a disease which constipation always is, and, though usually associated, the former may exist without the latter. Then, again, constipation is a relative term, seeing that remarkable differences in individual habits are not incompatible with ordinary health, and, while two motions daily may be the normal output for one person, another may find life tolerable with an interval of days, and even weeks, between the alvine dejections. These considerations lead us up to a definition of what constipation really is, viz., a diseased condition of the alimentary canal characterised by a modification of function which results in the pathological retention of faecal matter. We are all of us acutely conscious of the importance to the maintenance of a proper standard of health by methodical evacuation of the intestinal contents, and we can appreciate the appositeness of the remark attributed to "the old physician," that if his bowels moved naturally he felt sure that he would not die that day. In the hurry and turmoil of modern life, particularly in our large cities, attention to this function is made a matter of convenience, and disease is the harvest of neglect. One of the most obvious and familiar causes to which the author calls attention is the habitual use of purgative medicines, fostered and encouraged by conscienceless advertisers whom he would gladly see suppressed by legislative enactment. In this country, at any rate, public opinion, we fear, is not yet ripe for legislative interference with the intestinal functions, but undoubtedly the medical profession, by educating the public on this matter, might accomplish much. Without going into the details

of the author's elaborate classification of the causes of constipation, there is one point which is specially worthy of attention, viz., painful affections of the anus. Defæcation is largely a voluntary process, and the prospect of acute pain unquestionably acts as a deterrent which tends to the formation of a disastrous habit, productive of further local mischief and constitutional disturbance. Even more, the consciousness that defæcation is going to be painful has a directly repressive effect on peristaltic movement, thus fostering a tendency to faecal accumulation. We emphasise this fact because minor, but nevertheless painful, affections of the anus do not, perhaps, receive the attention which they merit from this point of view. The practitioner is but too apt to accept the patient's bashful, incomplete statements without taking the trouble to ascertain for himself the condition of this aperture. We would impress upon him the desirability of his cultivating proctology as an accomplishment, for by so doing he will be enabled to remedy many cases of obstinate constipation, and to save his patients much avoidable suffering.

THE WINTER SESSION.

THE opening of the Medical Schools for the winter session seems to have been shorn of part of its importance as an academical event by the fact that so many students now find it advantageous to commence their studies in May instead of October. Moreover, the ceremonial with which in years gone by teachers and students were wont to invest the occasion has been greatly curtailed, indeed, in about half the schools, not even the time-honoured introductory lecture has been maintained. The truth is that this lecture has become a burden too great to be borne, either by the younger member of the staff, upon whom the irksome task devolved, or by the students who had to listen to it, at any rate, after the first time. Occasionally the services of an oratorically disposed outsider have been requisitioned, but the experiment proved a hazardous one because no layman could possibly be in a position to discuss the aspirations of the medical profession in any save the most general way, and there are too many ethical pitfalls into which the unwary and the inexperienced might fall, to the confusion of their sponsors. Still the opening of the winter session cannot but be a red-letter day in the calendar of the neo-student. It is the occasion on which he is first introduced to his new and strange surroundings, and comes into contact with the men with whom he will, for five long years at least, have to work cheek by jowl. It is some time of course before the new student can find his way about, and still more before he begins to feel at home. He soon learns to appreciate the abyss which separates him, a first year's man, from his fellows of the second and subsequent years; indeed of the latter he sees very little, they having abandoned the dissecting room and physiological laboratory in favour of the wards

Before he has recovered his equanimity the new student has to run the gauntlet of the secretaries of the various athletic clubs to which he is cordially invited to subscribe, an invitation which he has seldom the courage or even the desire to withstand, glad as he usually is to sink his individuality in an organisation of some kind which shall mitigate the lonesomeness of the *début*. Then he has to set about providing himself with books and instruments, and we get the *petite bourse* where superannuated editions and implements are offered for sale by the wily seniors. After taking cognisance of the schedule of lectures, the hours at which they are to be delivered, and the various ways in which the days are to be employed, the new students pair off, some to set their lodgings in order, others possibly to places of refreshment or amusement by way of inaugurating the new life. And there we leave them with all the novelty of their career fresh upon them, full of hopes and aspirations, in some instances to be amply fulfilled, in others condemned beforehand to disappointment.

Notes on Current Topics.

The Use of Diphtheria Antitoxin in Australia.

DR. RAMSAY SMITH, Senior Physician to the Adelaide Hospital, South Australia, has been taken to task by a medical man in the Colony for not treating diphtherial patients under his care in the hospital with antitoxin. The criticism was based upon a statement of Dr. Smith's to the effect that antitoxin had never been used, and there had never been a death from diphtheria in the hospital. Whereupon the somewhat out-spoken comment of the practitioner was: "I must conclude that either the diagnosis was greatly at fault or that Dr. Ramsay Smith has had phenomenal good fortune, or that some other method of treatment has been employed which has not occurred to the rest of us poor mortals, and which is only vouchsafed to and permitted to be used by such deified individuals." The burden of the criticism further proceeds "the public have a right to expect that they will be treated in a public institution by the most up-to-date and approved methods, and that a medical man holding such a responsible position as Senior Resident Physician will be cognisant of, and ready to use, all the latest and best known remedies. In a letter to an Australian contemporary, Dr. Ramsay Smith publishes a spirited reply. He explains that the credit of the good results of the treatment of diphtheria at the Adelaide hospital is due not to him, but to the Hon. John A. Cockburn, M.D., the present Agent-General for South Australia, and that if the criticising practitioner desires to learn what the method of treatment is, it will only be necessary for him to attend at the hospital, and ascertain for himself. No doubt, many in this country would be glad to be informed as to this method, and Dr. Smith would be conferring a favour

upon the profession generally by making known through the medium of a medical journal the means by which he is able to obtain such successful results in diphtherial cases without resorting to antitoxin. Clearly there can be no necessity for using the antitoxin, even in Australia, if other means can be employed which prove to be equally successful. We trust to hear more from Dr. Ramsay Smith upon this subject.

Bile as an Antiseptic.

IT is an experience common to all progressive learned professions to witness a constant dismissal of beliefs as their knowledge of exact laws is extended. In the medical world to-day's abandonment of yesterday's entrenched position is a lesson acquired by the student before he is out of his apprenticeship. For all that, it will come to the middle-aged practitioner as somewhat of a shock to be required to unlearn the conviction impressed upon him in his earlier days that one of the functions of the bile in the human intestine was its action as an antiseptic. The chief reason for that cherished conclusion was the observation that the faeces became particularly offensive when the flow of bile was obstructed. A German investigator, Morse, has made an experimental research into the power of bile to control the processes of putrefaction and fermentation both inside and outside the body. Briefly summed up, the conclusions were that bile exerts no influence on the putrefaction of albumen in the intestine; that the presence of bile apparently increased the bacterial putrefaction of albumen outside the body: that fermentation of carbo-hydrates was increased in the presence of bile, and that concentrated bile retarded the growth of bacteria, but the action ceased after twenty-four hours. These experiments are of sufficient suggestive importance to demand careful testing. The fact that a great deal of intestinal digestion appears to be carried on by bacterial agency would, if proved, go a long way to disprove the assumed antiseptic properties of bile. It should be remembered, however, that the teachers of a generation ago were not in possession of the data afforded by modern bacteriology.

Coroners' Courts.

GRIM though its purpose be, the coroner's court but too often sadly lacks the dignity which magistrates and judges contrive to import into the proceedings in their respective spheres of influence. For this the satellites of the presiding genius are to some extent responsible. The coroner's officer, for example, has a nasty little habit of soliciting gratuities from sorrowing relatives, the mortuary keeper follows suit, and last, but not least, there is the crowd of seedy looking *soi disant* reporters who assemble when there is any family scandal, and who hold out itching palms to be covered as the price of silence in the press, a bargain which, even when made, is not unfrequently violated, to the distress of the relatives who were hoping to be spared the further

pang of publicity. Even professional witnesses are not exempt from the attentions of the coroner's officer who, as cashier, seldom fails to lay siege to the odd shillings when paying over the fees, a pretension which every self-respecting medical man should take care to resent. A coroner's court is a gruesome place at best, but the presence of these callous solicitors adds considerably to its repulsiveness. Coroners themselves might do much to purify the courts from these flaws, especially by selecting their officers from among a less venal class of men, or, at any rate, by repressing their tendencies. In this they would certainly receive the support of the constituted authorities, and the hearty approval of public opinion.

Homœopathic Assurances.

In the course of a series of lectures on the homœopathic treatment of tropical diseases recently delivered by a Dr. Hayward, some very remarkable statements were made which, we fear, would not bear close scrutiny. We are told that while the average mortality from yellow fever is 27.7 per cent., the mortality under homœopathic treatment is only 7. As the actual statistics are not given in the report before us we cannot very well criticise them; but we should imagine that the number of patients suffering from this fell disease who underwent homœopathic treatment must be far too small for it to be possible to base any trustworthy conclusions thereupon. A similarly bold and equally unauthenticated statement is made in respect of cholera. Coming to typhoid fever we are assured that, though a germ disease, homœopathic medication does much to modify the course and shorten the duration thereof. Statements such as these may pass muster with the uncritical laity, to whom the lecturer was addressing himself, but must excite contempt among those who know what little influence purely medicinal treatment has in any of these diseases. It is this very want of candour on the part of the practitioners of that ilk which makes it well-nigh impossible for self-respecting practitioners to meet them on cordial terms, and so long as the arts of the mountebank are resorted to to bolster up this particular system so long will its adepts be ostracised by their fellows. It goes without saying that if homœopathy accomplished even a fraction of what its advocates claim for it, it would long since have brushed all alternative methods of treating disease out of the field.

Mr. Chamberlain and the Malarial Inquiry.

It would seem that some friction is likely to ensue between the Liverpool School for Tropical Diseases and that which is being organised in London. It will be remembered that the whole inquiry into the question of the malarial bearing mosquito has been carried on by Major Ross, in connection with the former School, and that the Malarial Commission sent to the Gold Coast by the Liverpool School authorities is, under Major Ross, still prosecuting its inquiry. Despite, however, the valuable work to which this Commission has specially devoted its energies, it would appear that quite recently a

despatch was sent by the Secretary of State for the Colonies to the presidents of the various colonial branches of the British Medical Association, and among them the branch at the Cape of Good Hope, requesting that medical men practising in tropical lands should send specimens of the various species of mosquito, in malarial districts, for investigation to the School of Tropical Diseases in London. This fact, taken in conjunction with the refusal of Mr. Chamberlain to grant any official assistance to Major Ross's inquiry, appears to be rather significant. Clearly, if the Liverpool School of Tropical Diseases requires official assistance, it should be granted. Why should the Colonial Secretary favour the London school? Each school is working upon the same lines and has the same objects in view, namely, the dissemination of the knowledge of tropical diseases. To encourage, however, any rivalry between the two institutions is a policy which cannot be deemed wise, and we, therefore trust that in the future the Secretary of State for the Colonies will be careful to extend the same patronage and assistance to the Liverpool school, as in the past he has done to that established in London.

English Medical Men in the Transvaal.

THE Boers are no respectors of persons, and their treatment of English medical practitioners with whom they may happen to have a grievance leaves a good deal to be desired, as the following example will show:—A practitioner was summoned to attend the little child of a Boer, but refused to respond to the summons inasmuch as another medical man had charge of the case. In consequence of this refusal the Boer lodged a complaint against the practitioner at the next meeting of the local governing body of the district. Accordingly, a resolution was passed by the latter pledging the members thereof to boycott the practitioner, and a young practitioner from a neighbouring part was invited to settle in the district, and was promised the support of the local authorities. This perfectly unwarrantable step was taken merely because the medical man in question, by acting in accordance with professional usage, displeased a person who was the patient of a *confrère*. Medical practice under such conditions could scarcely be enviable, but now the time seems to have arrived when old scores will have an opportunity of being paid off.

An Anti-Vaccination Congress.

It is absolutely essential for the anti-vaccination faddists to keep on moving, and continue to make a show of resistance to Jenner's prophylactic. The latest information respecting their movements is that they intend to hold an International Congress in Berlin in the course of a few weeks, at which it is anticipated that representatives from all the European countries and the United States will be present. Moreover, it is announced that "Doctor" Phelps, of London, will address the Congress. We confess that this is the first that we have heard of such a gentleman. Probably an ardent anti-vacci-

nationist of this name, who is generally described with a military title, is here meant, and if so, we would suggest that he would be better employed in volunteering for service in South Africa than in disseminating nonsense upon public platforms. However, some satisfaction may be derived from the fact that probably the anti-vaccinationists have been woefully disturbed by the recent progress of vaccination in this country, as shown by the official returns. The Act of 1898 was a concession in their favour, and the results of its working must have greatly astounded them. Indeed, judging from the official returns, despite the conscience clause, vaccination seems to have been made more or less popular by the Act of last year. Thus, Lord Lister's "tremendous experiment" has proved, quite beyond expectation, to have been an excellent thing. All that is now wanted is for the anti-vaccination party to enter upon a well-earned retirement, and thus, with as little fuss as possible, admit their defeat.

The Medical Society of London.

THE 127th session of the Medical Society of London will be inaugurated on Monday next, October 9th, by an address to be delivered by the President, Dr. Frederick Roberts. This will be followed by a discussion on "Personal Experience in Relation to Serum Therapeutics and Antitoxin Treatment." It is announced that the Lettsomian Lectures on "Cancer of the Breast" will be delivered in March and April by Sir William Mitchell Banks, and the Oration in May by Dr. Kingston Fowler.

How are We to Feed our Babies.

THE question of the proper feeding of babies is one not only of weight to the individual, but of the utmost collective importance to the community. Healthy babies mean a healthy nation, and *vice versa*. Of course, it may be taken as an axiom that the proper food for the infant is mother's milk, nothing more and nothing less, but unfortunately Nature's pabulum is not always available under the stress of modern civilised life. Then comes the great problem which heads this paragraph, namely, How are we to feed our babies? To that antiquished question we doubt if many medical men could give a clear and properly substantiated answer. For some inscrutable reason or the other the curriculum that exacts from the student a minute knowledge of the finest ramifications of remote branches of nerves and arteries, does not ask for any proof that he has considered the crucial point as to how the young of his species should be nurtured. That is possibly because the exigencies of consulting practice have not brought the facts of the case before his examiners, who are, as a rule, quite ignorant of the needs of general practice. There can be little doubt that a well-written and carefully edited summary of all kinds of baby feeding, natural and artificial, would be of great value to the general practitioner. We wonder when the common sense of the main mass of the profession will insist upon the rational education and examination of medical students.

The Antidotal Properties of Permanganate of Potassium.

THE case with which permanganate of potassium gives up its oxygen when brought into contact with oxydisable substances renders it of extreme value as an antidote in respect of many, if not indeed of most, of the alkaloids. It is admittedly the most efficacious agent we possess in cases of, poisoning by opium and its alkaloids, and it has been estimated that a given weight of the salt will neutralise a similar quantity of morphine. This valuable property, however, is not limited to alkaloids of the morphia series. Stokvis recommends it as an antidote in poisoning by phosphorus, which it transforms into orthophosphoric acid. Autail has shown that it neutralises the toxic properties of oxalic acid, the cyanides, strychnine, colchicine, and muscarine. Lacerda long since recognised it in the treatment of serpent bites, while Durante and Giodano found it equally of service in attenuating the symptoms resulting from the bites of insects. Somewhat later Hugouneng demonstrated its antidotal action in respect of caffeine, cocaine and alkaloids of the atropine group, and still more recently Paratore has shown that curare, nicotine, and aconitine are also destroyed thereby. Comparative experiments with the permanganate show it to be far more trustworthy than tannin or iodine in the treatment of strychnine poisoning, whether employed hypodermically or for washing out the stomach. It would seem indeed that the permanganate is the agent *par excellence* to which the physician ought to have recourse whenever he is confronted with a case of suspected alkaloidal poisoning. In view of these marked antidotal properties, it is possible that the administration of permanganate might prove of service in the frequent cases of ptomaine poisoning, the lethal agent in these cases being presumably alkaloids, alkaloids, moreover, which are peculiarly susceptible of oxidation.

Workmen's Injuries.

ALL humane men most welcome the principle of compensation for injuries which is now enforced under the Employers' Liability Act; but the working of the measure still requires amending in details before the working-man will secure its intended measure of justice. A case settled last week in Marylebone County Court brings some of these defects into relief. A workman engaged in cutting mouldings by means of a machine slipped and fell with his left hand against some rapidly revolving and unguarded knives, whereby four fingers and a thumb were instantly cut off. Plaintiff was entitled, according to the statement of counsel, to one pound a week for life. The judge, however, fixed the sum of £200 to be paid in full satisfaction of all claims by the plaintiff against the defendant. With regard to that part of the decision, most folk will be inclined to think that defendant was let off very lightly in commutation of a life-charge of a sovereign a week. Four years' purchase, for instance, would not satisfy the learned judge who settled this case as a basis for

arbitration in selling a house, or in fixing the amount of his pension. That is not all the fault we have to find with Judge Stonor, however, for in addition to awarding that comparatively trifling recompense for so terrible a mutilation, he ruled that no costs would be allowed. Anyone who knows the cost of legal proceedings, especially when undertaken by poor persons on somewhat speculative issues, will be able to form a pretty shrewd estimate of the extent to which the £200 will be further whittled down. A short amending Act is evidently needed to establish the basis of commutation of penalties, and to make all verdicts against employers carry costs. One would like to know if criminal proceedings could not be instituted against the employers who used the unfenced machinery.

Pills Fatal to Children.

AN inquest held at Canning Town last week upon the body of a child of thirteen has disclosed some usually unsuspected dangers of home drugging with chemists' wares. The mother of deceased asked a friend to get some magnesia, but instead of that some pills were brought, and two of them were administered to the child. A medical man was called in later, but found deceased unconscious and dying. He subsequently made a post mortem examination of the body, and came to the conclusion that death was due to collapse following diarrhoea, caused by some irritant acting on a delicate condition. The chemist from whom the pills were purchased said that they contained capsicum and aloes, and were manufactured specially for him. The jury returned a death from misadventure, and added a rider requesting the coroner to call the attention of the Chemists' Society, or the proper authorities, to this case, with the view of protecting the public in the future. This attitude on the part of the jury is somewhat unusual, for those bodies are generally all on the side of the prescribing chemist. At the same time, many rational men would feel inclined to go a good deal further, and, after securing a full analysis of the pills in question, to demand legislative control over this reckless, irresponsible vending of dangerous drugs by chemists all over the United Kingdom. Not only do these tradesmen encroach upon the ground that should be occupied by legally qualified medical men, but by their illegal prescribing they further constitute a standing menace to the health and the lives of Her Majesty's lieges.

Medical Service in State at St. Paul's.

ON Thursday, October 19th, at 7.30 p.m., the Bishop of Stepney will preach at St. Paul's Cathedral to the members of the medical profession. The Lord Mayor of London will attend the service in state. The service is the annual one organised by the Guild of St. Luke, and is always a brilliant ceremony, as many doctors who are graduates or Fellows of the Royal College of Surgeons attend in academical robes. The music will be rendered by a choir of over

two hundred voices provided by the London Gregorian Association, so that the whole service is likely to be most solemn, brilliant, and impressive. Admission to the space under the dome will be by ticket only. It is trusted that practitioners not wearing robes will not be deterred from attending, as all are equally welcome. On account of the great demand for seats it has been found necessary to limit the number of tickets issued for friends, and the executive committee will be unable to grant more than one extra ticket to those not wearing academical costume, and two to those who have expressed the wish to wear robes and join the procession. Application for tickets, with information as to robes must be made on or before the 8th inst., to the Registrar of the Executive Committee, 24 Somerset Street, Portman Square, London, W.

The Destruction of a Town for Sanitary Reasons.

THE Japanese are a go-a-head race, as everyone knows, but they are about to achieve a record in sanitation. The Government have just ordered the destruction of a town, Teckcham, in Formosa, inasmuch as sanitary experts have declared it to be unhealthy and unsuitable for human habitation by reason of having been built upon a swamp. The terms under which the edict of the Government will be carried out are somewhat interesting. A new locality has been chosen for the town, and sites for the houses will be presented to the citizens, occupying as near as possible, the same relative position, but the citizens will be called upon to bear the cost of moving their belongings. Whether the community in question are satisfied or not with the change determined upon, the Government will carry it out. The novelty, however, of the edict is somewhat startling, and yet this record in sanitation is only another instance of the enterprise and remarkable progress shown by the Japanese nation.

The Remuneration of Public Vaccinators.

THE old saying, "Tis the number that pays" has been amply illustrated in the case of the public vaccinator of Birmingham. For the half-year ending June last this official received for vaccinating children no less a sum than £592 2s. 6d., which was paid by the Birmingham Guardians. *Pro rata* this means an income of £1,184 5s. per annum, quite a princely amount to draw for public services of the kind in question. The payment was based upon the minimum fee allowed by the Local Government Board for each successful case of vaccination. But despite this fact, the guardians think that the total amount is excessive, and that the minimum fee should be still further reduced. But Boards of Guardians are very difficult to please. They appear to have overlooked the fact that it is far better to have paid their public vaccinator yearly £600 for successful cases of vaccination than for the people to remain unvaccinated, and so expose the town to the risk of an epidemic of small-pox, which might ultimately cost the ratepayers £20,000.

The Mill for Female Doctors.

It is evident that the chief centre for the manufacture of female practitioners is Switzerland. Out of a total of 1,153 students attending in the five Swiss Universities, 344 were women, and of these only 24 were Swiss. Out of 247 students at Berne 87 were women; and out of 350 at Zurich 123 were females. These figures have a serious bearing on the often debated problem of the recognition of foreign medical qualifications in Great Britain, for even the most liberally minded educationalist must hesitate to admit three hundred Swiss girl students annually to the privilege of medical registration in this country, not to speak of the crowd of those qualified in other countries.

Typhoid and Dairies.

THURLES has been the scene of a serious outbreak of typhoid which has been clearly traced to the milk supplied from a local dairy, one of whose members contracted the disease. Fifteen customers immediately showed symptoms of it, and some died, and eventually, fifty other neighbours resident in the immediate neighbourhood became infected. The water consumed by these people was derived from pumps within reach of infection, and it was ascertained to be polluted. At length the guardians rose to the necessity of providing a safe water supply, and the work has been put in hand.

PERSONAL.

M. LACOURT is the first graduate to receive the newly created degree of Doctor of Pharmacy of the University of Paris.

MR. HAROLD L. PALMER, M.R.C.S.Eng., L.S.A., of Newtown, North Wales, has been appointed a magistrate for the county of Montgomery.

DR. FRANCIS CHARLWOOD TURNER, Physician to the London Hospital, has had conferred upon him, *honoris causa*, the degree of D.C.L. of the University of Durham.

DR. RICARDO JORGE, the principal Medical Officer in charge of the Plague Commission at Oporto, has asked to be allowed to discontinue his work in connection with the combatting of the plague, both on the ground of his own state of health and of the hallucination of public opinion.

FEMALE practitioners cannot complain that they have not fair play in Scotland. A few days since, the Hospitals Board of Govan, a district of Glasgow, appointed Miss Augusta Boyes, M.D., Ch.B., as resident physician to its fever hospital, and the Edinburgh Victoria Hospital for Consumptives appointed Dr. Anne Mercer Watson to be resident physician.

THERE are, doubtless, many among our readers who have passed a portion of their time of study at the University of Vienna, and will remember with kindly feelings the genial Professor of Medicine, Hofrath Dr. Theodor Puschmann. The announcement of his sudden death at the early age of fifty-six, will be received by them with

feelings of sincere regret. The deceased Professor wrote, among other works, a "History of Medicine in Vienna, during the last Hundred Years," which was translated into English.

Scotland.

[FROM OUR SPECIAL CORRESPONDENT.]

"**LORD KELVIN**, Professor of Natural Philosophy in the Glasgow University, 1846-1899," is the title of a volume which Messrs. Maclehose, University printers, Glasgow, announce will be issued shortly. The volume has been in preparation for some time, and is to be published by the desire of a number of Lord Kelvin's friends. Professor Fitzgerald, of Trinity College, Dublin, has written a biographical sketch of Lord Kelvin for it, with special reference to his scientific work. It will also contain a full account of what is of permanent interest in connection with Lord Kelvin's jubilee, and appendices giving the names of all those who were invited by the University and the City to take part in these celebrations. There will be two editions, a special and an ordinary, and the illustrations of the special edition will consist of photogravures, including a portrait of Lord Kelvin, of the old and the new college buildings, especially of those portions of them more intimately associated with Lord Kelvin's name.

DEATH OF LACHLAN MCPHERSON.—On Monday, September 26th, Lachlan McPherson, Bedellus to the Glasgow University, passed over to the majority, which will be regretted not only in Glasgow but throughout the world where Glasgow students have made a home. At the time of his death he had entered upon his 83rd year, having been connected with the University for forty-six years. During this long period he served under four Chancellors, four Principals, sixteen Lord Rectors, and more than two hundred professors. Four years ago he celebrated his golden wedding. A man of fine presence, he bore himself with impressive stateliness in his public appearance as bedellus. In his intercourse with students, he was the kindest and most encouraging of men; most entertaining in his reminiscences of olden times in the old college in the High Street, which made his listeners open wide their eyes with pleasure and astonishment, and also of his more recent experiences at Gilmore Hill. His funeral took place on Friday last, at which the Principal and a large assemblage of professors and the public were present.

A WINDFALL FOR GLASGOW CHARITIES.—By the will of Mr. James Brown Thomson, of Glasgow, the charities of that city have benefited to the extent of nearly £80,000. The University receives £10,000, and the Royal Infirmary £6,000.

Manchester.

[FROM OUR OWN CORRESPONDENT.]

ST. MARY'S HOSPITAL.—This old-established institution for women and children is moving its home. The foundation stone of the new hospital is to be laid by the Countess of Derby on Monday, October 9th. It is to consist of two portions, each distinct and furnished with separate entrances. One will be devoted to obstetric cases, the other to the treatment of diseases of women and children. The hospital is intended to accommodate 125 in-patients. Provision is to be made for the training of medical students, nurses, midwives, and monthly nurses.

THE SUMMER MORTALITY.—During the last fourteen weeks 926 deaths have occurred in Manchester from diarrhoea and English cholera, 713 being of infants who had not completed their first year of life. The cooler weather, however, is now having its effect, and last week the deaths went down to 77, as compared with an average

of 114 for the six preceding weeks. In addition to these sixteen deaths were recorded with diarrhoea as a secondary cause.

OWENS COLLEGE.—The recently published calendar shows the medical department to be in a flourishing condition. Of the 1,067 students of all departments, 428 are "medicos." The medicine class numbers 115. As regards examinations, 215 are working for the degrees of the Victoria University, 47 for London, and 10 for other universities. For the "Conjoint" there are 48 and 13 for the "Triple." In special departments there are 41 Dental, 11 Pharmaceutical, and 16 Public Health.

The Introduction address of the winter session was delivered on October 2nd by Sir James Crichton-Browne, LL.D., M.D., F.R.S., on "The Quest of the Ideal."

ROYAL INFIRMARY.—Various changes have recently taken place in connection with the teaching staff. The appointment of Dr. Reynolds will do much to strengthen the medical side. Dr. Kelynack has been appointed Medical Registrar in the place of Dr. R. T. Williamson, who has resigned. Dr. Moore has been appointed to succeed Dr. Kelynack as Pathologist. The new clinical laboratory is in full work under Dr. Fothergill. The discussion of the much vexed question of the new infirmary site will shortly be reopened. A bust of the late Sir Joseph Heron has been presented to the Infirmary Board. "James," the head porter, will be remembered by many generations of students, practitioners, and patients, for he has been a familiar figure at the infirmary for forty-five years. He now retires on a well-deserved pension.

THE FORTHCOMING CONFERENCE ON HOSPITAL REFORM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I feel some regret at the announcement made in your last issue that Mr. Holmes is to take the chair at one of the meetings of the association interested in the Reform of Hospital Abuses. Some years ago the Charity Organisation Society and the British Medical Association combined and endeavoured to supply what it was considered the working classes most wanted—namely, some good system by which medical and surgical advice and treatment could be provided which would take the place of the out-patient departments of our hospitals, to which many resorted without any claim, and by which much injury was done to the great body of general practitioners. The relation between the hospitals and the public through subscribers letters was destroyed when the doors of out-patient departments were thrown open, and the fact that no letters are required, was freely advertised. The greater the number of out-patients, the greater was made the claim of any hospital on the charitable public. This abuse was not likely to be reformed by the physicians and surgeons attached to them, and how far Mr. Holmes and his friends succeeded by their endeavours, they have not disclosed. If the great body of medical practitioners throughout the country were really suffering by the indiscriminate relief afforded by hospitals, it will be well for them to act quite independently of those who are or have been connected with hospitals. It seems to me probable that the want of funds will produce more effect on the present defects of the out-patient system of hospitals than anything else, and the best plan which practitioners can adopt to assist in this is to use their influence with the public by discouraging support to hospitals.

It is important that medical practitioners throughout the country should be careful to avoid any charge that may be brought against them of being influenced chiefly by self-interest in their wish to reform the abuses of hospitals. The question why

the public should prefer hospitals to practitioners is to some extent due to the idea that specialism is preferable in most maladies, and the general practitioners have only been applied to when sudden illness or other circumstances prevented patients from going to hospitals. The very poor pay from clubs and the working class generally has induced practitioners to look to the middle and upper classes for remunerative practice, and it seems now as if the reason why they are beginning to attack the out-patient system is really because they are losing this class of patient. Whether any system can be organised to provide what hospitals supply at reasonable rates, is the question of interest, and it would be well to keep very clearly in view what are the public wants and how the profession must meet them.

I am, Sir, yours truly,

A PRACTICAL REFORMER.

FEVER ACCOMMODATION IN DUBLIN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In an annotation on page 329, you speak of Dublin having one special fever hospital of 120 beds (of which about eighty are usually occupied). Cork Street Fever Hospital—the only special fever hospital in Dublin—has really 240 beds, and its convalescent home, Beneavin, has twenty-six beds. The average number of beds occupied in Cork Street Hospital last year was 165.91, and during the present epidemics our numbers have not fallen below 220. Your article also neglected to mention that Sir Charles Cameron's panacea was a Corporation hospital of 80 beds!

I am, Sir, yours truly,

E. MACDOWEL COSGRAVE, M.D.,
Physician, Cork Street Hospital.

Gardiner's Row, Dublin, September 27th, 1899.

[The number of beds available in Cork Street Hospital is stated in the latest edition of "Burdett's Hospital Annual" as 220, and the average number occupied as 193 (see page 201 of Annual). When writing, however, we preferred to take the figures given in the report of the Dublin Hospital Board published in the most recent issue of the "Irish Medical Directory," and these state the accommodation as we have given it—i.e., 120 available beds, and 101 occupied on an average. The convalescent home at Beneavin was not available at the date of this report. It is scarcely necessary for us to say that we never regarded the proposed isolation hospital as a substitute for, but rather as an auxiliary to, Cork Street, the Hardwicke, and other existing fever hospitals, and we think it is beyond question that such additional accommodation is essential to meet the strain of an epidemic. It appears to us that Sir Charles Cameron's estimate of £250 per bed is excessive, but as it appears that the Dublin Corporation is ready to throw £28,000 of the citizens' good money after the £91,000 already wasted in providing villas at £436 a piece for well-to-do artisans we are not disposed to quarrel with Sir C. Cameron's scheme because it is somewhat extravagant.—ED.]

SANITARY REMOVAL BY FORCE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I see by this week's MEDICAL PRESS you take exception to the way the law is set in force to carry out the above Act in London, but I think you do so under a misconception.

I believe the Acts for England and Ireland are precisely similar. In Dublin, when the Medical Officer of Health for a district finds it necessary to put compulsory removal in force, he fills up and signs a certificate setting forth:—" — is suffering from a dangerous and infec-

tious disease, and is without proper lodging and accommodation," which form he gives to the sanitary sub-official. The latter goes with this certificate to the police court, and the presiding magistrate signs a warrant for the removal. The sanitary sub-officer without this certificate has no authority or power to act.

I am, Sir, yours truly,
HENRY W. OULTON, M.D., M.O.H.

17, Up. Fitzwilliam Street, Dublin,
September 30th, 1899.

Obituary.

SIR CHAS. ALEX. GORDON, K.C.B., M.D.

It is with sincere regret we have to announce the death of Sir Chas. A. Gordon, at his London residence, Westbourne Square, on Saturday last. Deceased was a personal friend of the editorial staff of this journal, he having contributed to its columns pretty regularly during the past quarter of a century, and greatly attached himself to all by his urbanity and great cordiality. Immediately after qualification Sir Charles entered the Army Medical Service, and probably saw as much fighting as any officer during the present century. He was engaged during the whole of the Indian Mutiny, and had entire medical charge of the Army Medical Service for many years before leaving India. On his return to England he was sent on a special mission by the British Government as medical representative during the Franco-Prussian war, and was in Paris during the whole of the siege and bombardment, at the conclusion of which he published an exceedingly valuable report in book form, entitled "Lessons on Hygiene and Military Surgery from the Franco-Prussian War" (London: Bailliere, Tindall, and Cox), which created considerable stir at the time, and is still referred to as a standard authority on subjects with which it treats. Sir Charles was a voluminous writer. He wrote for the love of it, and steadily declined payment for literary work, the thought that he could impart useful knowledge from his vast experience which might benefit his fellow men was a sufficient incentive to work, and throughout a long acquaintance the writer of this brief notice can honestly affirm that Sir Chas. Gordon was the most sincerely modest and unobtrusive of men it has been his privilege to meet, a gentleman in the truest acceptation. He was an officer of the Legion of Honour of France, an Hon. Surgeon to Her Majesty the Queen, held innumerable medals and clasps, and was created a Knight Commander of the Bath on the celebration of the Diamond Jubilee two years ago. He was one of those to whom might have been applied the epilogue to Horace, men who "do good by stealth, and blush to find it fame."

Laboratory Notes.

INFANT AND INVALID'S FOOD.

We have received from the Infant and Invalid Food Co., Ltd., Cereal Buildings, 54, City Road, London, a sample of their "I. and I. Food," and find on analysis that it has the following composition:—

Albuminoids	11.81 per cent.
Moisture	8.08 " "
Fat and Oil	3.19 " "
Mineral matter	1.42 " "
Fibre	1.12 " "
Carbohydrates (by diff.)	74.37 " "

A careful microscopic examination confirms the statement in the pamphlet accompanying the sample that this food "is a carefully prepared mixture of various cereals," and also proved the absence of all moulds and deleterious substances, and an undue proportion of indigestible fibre or husk.

The analytical figures given above show that the food contains a notable proportion of fatty matters, while the nitrogenous or flesh forming constituents are present in

suitable proportions. The amount of moisture is by no means excessive. The mineral matter consists almost entirely of phosphates of calcium and potassium, which are essential to normal nutrition, and are moreover valuable as aiding the due formation of bone.

ARCHER'S COGNAC.

We have examined a sample of Eau de Vie Cognac, imported by Messrs. Edward Archer and Co., Malvern, and find on analysis that it gives the following figures:—

Absolute alcohol (by weight) 40.5 per cent. (or 83.9 per cent. proof spirit). The extractive matter is equal to 0.64 grammes per hundred cubic centimetres. This figure is consistent with the due maturing in a sherry cask, which is part of the process in the preparation of genuine brandy.

The acidity is .045 grammes per hundred cubic centimetres calculated as tartaric acid.

The amount of ethers is equivalent to .04 grammes per hundred cubic centimetres calculated as acetic ether. This figure shows that the brandy has been duly matured for a sufficient time to allow of the development of those volatile products on which the delicate flavour and bouquet of the finished article depend.

We are satisfied that this brandy is of high quality, thoroughly genuine, and worthy of commendation for medical use.

TANNOFORM.

We have received from Merck's London office samples of Tannoform, a condensation product of tannin and formaldehyde, which has come into use in the treatment of hyperidrosis and bromidrosis, in virtue of its astringent and antiseptic properties.

It is presented in two forms, the Tannoform Substance and the Tannoform Dusting Powder. The latter is put up in an ingeniously devised paper dredger, which facilitates the dissemination of the powder evenly over the affected surfaces.

Tannoform is not only a siccative antiseptic of the first order, odourless and absolutely unirritating, but it answers all the requirements of an intestinal antiseptic for use in fermentative disturbance of the alimentary canal associated with diarrhoea and gas formation. The average dose for internal use is, in adult cases, eight grains, and four grains in children's cases, to be given in the form of a cachet.

Literature.

HOSPITAL REPORTS.

THE MIDDLESEX HOSPITAL REPORTS. (a)

The preface to this Report tells us that it is arranged on the same plan as that of its predecessor. The plan is all right, but we sincerely wish the volume had a stiff binding that we might give it a place on our book-shelf, and that it was not so closely printed. From time to time we have to put the volume down, as we find a few pages of its closely printed statistics make our eyes ache. We feel this all the more for the volume is rich in information, well arranged, and excellently summarised, but of what use is all this if the type is unreadable and the paper back unfits the book for the book-shelf. The work done during the year was large and creditable. Such of the papers in the Report that we could read were well worthy of study, and yet for a small outlay this is practically lost to the medical profession.

A severe headache and a series of coloured rings before the eyes are too much to pay for the pleasure and advantage derivable from reading the Report.

Of the latest of statistics the most interesting is the P. M. Table with its abstract of 318 examinations. Included in the last is an account of injury to the internal mammary artery with wound of the pericardium and

(a) "Reports of the Medical, Surgical, and Pathological Registrars for the Year 1897." London: H. K. Lewis. 1898.

other by hydrochloric acid there were no excoriations about the mouth in either case.

From the Medical Registrar's report we learn that antitoxin was used in the treatment of diphtheria in nine cases in 1894; in 29 cases in 1895; in 25 cases in 1896; and in 17 cases in 1897. In two cases an erythematous rash followed the administration of antitoxin, but otherwise no unpleasant results occurred.

ST. BARTHOLOMEW'S HOSPITAL REPORTS. (a)

THE present volume of this great hospital's reports is, as a measure of the scientific advance of medicine, of more than usual interest. These reports are really the year-books of scientific medicine. They show the prevailing type of sickness of the preceding year, they give the effects of our social and domestic life on the health; they show the influence of occupation, and they give the most generally approved system of therapeutics.

The practitioner who reads the reports of the principal general hospitals is well prepared to successfully hold his own in these days of keen competition in the profession.

Of the papers in the present volume the most interesting are Sir T. Smith's "Case of Abdominal Cysts;" Mr. Walsham's "X-Rays in Diseases of the Chest;" "On Pneumonia and Pneumococcus," by Mr. Turner; "Stomachic Phenomena," by Mr. R. Gitt; and Dr. Andrew's article, "The Growth and Work of the Pathological Department." We may add, that for a pleasant, chatty, well told record of a busy practitioner's life, we know none more enjoyable than that told in this volume by Mr. H. S. Webb.

From the surgical report we learn that 3,746 surgical cases were discharged, cured, or relieved during the year, and that 219 cases died in hospital.

During 1897, anæsthetics were administered 4,893 times, and it may interest those who, in season and out of season, advocate ether, to know that only 201 cases of etherisation are recorded as against 1,959 chloroformisations. Ether, it thus appears, was found suitable in no more than 4 per cent. of the cases requiring an anæsthetic, whereas chloroform was used in almost 40 per cent. of the cases, and this in London where ether is most zealously advocated, to the exclusion, as far as possible, of chloroform.

GUY'S HOSPITAL REPORTS. (b)

THE present volume opens with a valuable article, "Notes on Diagnosis," by Dr. Pye-Smith. It is a practical contribution to clinical medicine, well worthy of attention by practitioners and senior students. Indeed, we should like to see it published in pamphlet form, and in the hands of every senior medical student.

Mr. Jacobson and Dr. S. B. de Mesquita contribute a joint paper on "Epithelioma of the Neck," probably arising in a relic of the branchial clefts. "Mediterranean Fever," by Mr. Gerald Sichel, goes over the familiar ground that for a century has been trodden by observer after observer. In fairness to the author we must say that he advances our knowledge of the disease by showing that Vidal's serum method has materially facilitated the diagnosis of the disease, and that a Mr. Bruce has discovered its micrococcus. Needless to say, an antitoxin has been prepared as a therapeutic remedy.

As we read of the continually occurring mention of antitoxins we think we hear the emphatic pronouncement of Sangrado, "medical reading is waste of time, all treatment is but bleeding," if for bleeding we substitute antitoxin injections we get much modern medical practice.

The aggressive nature of surgery is well shown by Mr. Gifford's paper, "The Surgical Treatment of Unperforated Gastric Ulcer." He gives an account of three cases

in which operations were performed. As so many cases of gastric ulcer get well under the ordinary treatment of a regulated dietary and rest we cannot wholly approve of this heroic method. We think the omission of M. Dieulafoy's name, and the ignoring the good work he has done in this class of disease, is a mistake.

Dr. Poole's account of the typhoid epidemic at Maidstone occupies eighty pages, every one of which contains instructive reading; indeed, the article is one of permanent value to medicine.

The functional activity of retained testicle is the subject of a paper by Mr. G. Bellingham Smith. The author arrives at much the same conclusion as the bath attendant in the "Arabian Nights' Tales," as told in Burton's edition.

ENCYCLOPÆDIA OF MEDICINE. (a)

THIS enormous undertaking by Hofrath Drasche has now reached 183 parts, and is still far from being complete. The book is not a periodical, but a dictionary of medicine, surgery, chemistry, &c., comprehending all the special departments recognised in the curative art. The contributors exceed 200, engaged in the various specialities, who are scattered over the two German speaking empires of Austria and Germany proper. It may be noted, by the way, that 45 of these authors, or 22½ per cent., are located in Vienna itself. The other representative towns and cities are Prague, Berlin, Halle, Munich, Königsberg, Buda Pesth, Warsaw, Frankfurt, Giessen, &c. Each author confines himself to his own specialty on which he professes to be an authority. The views of other authorities from every quarter of the globe are also added where a diversity of opinion exists, so that this encyclopædia of medicine, although written by Germans, is not confined to views of the German speaking race, but is a brief synopsis of the latest knowledge for the specialist and busy practitioner who can read the language.

Haug has among his "Neoplasms of the Tympanum" a "reflex neurosis" associated with cough, sneezing, &c., that may be worth noticing as an example of the exhaustive nature of the work and its practical utility. This morbid condition is usually excited by the presence of polypi in the recessus epitympanicus near the perforation of the membrana Strapnelli. Troublesome symptoms may be induced and much anxiety suffered long before degeneration of the tympanum is manifested and the real nature of the case diagnosed.

The prognosis, like all other cases of polypi, depends on the nature, size, number, and duration of the growths, as small, soft, rapidly growing polypi recur very frequently. This recurrence has a tendency to produce caries or induce malignancy, which should be borne in mind during treatment. In treating these, alcohol and sublimate (0·1 of sub. to 100 of alcohol), trichloride of acetum, and chromic acid are the most potent.

Under "Prostitution" Jessner has a long history of its rise and fall, and the application of hygienic measures in the present age, as a means of modifying its ravages on the present and future generation. He does not coincide with Lombros' opinion that all who follow this calling, male and female, are irresponsible criminals, although he believes there is something in heredity. He agrees with penalising this trade and not legalising it, as is too much the fashion at the present time. The clinical histories of our hospitals are strong arguments in favour of suppression.

These samples imperfectly illustrate the meritorious utility of the work, and suggest how valuable such a dictionary of medicine will be to the inquiring mind.

THE PENYCUIK EXPERIMENTS. (b)

THE zebra stripes on the cover form a fitting introduction to the contents, which deal with the author's experiments in crossing zebras, and with the literature of the subject. Part II. consists of papers which have

(a) "Saint Bartholomew's Hospital Reports." Edited by Norman Moore, M.D., and D'Arcy Power, F.R.C.S. Vol. XXXIV. London: Smith, Elder and Co. 1899.

(b) "Guy's Hospital Reports." Edited by E. C. Perry, M.A., M.D., and W. H. A. Jacobson, M.D., M.Ch. Vol. LIII., being Vol. XXXVIII. of the Third Series. London, J. and A. Churchill. 1898.

(a) "Bibliothek der gesammten Medicinischen Wissenschaften für praktische Aerzte und Specialisten." By Prof. A. Drasche, Wien.

(b) "The Penycuik Experiments." By J. C. Ewart, M.D., F.R.S. Pp. xliii-177, Illustrated. London: Adam and Charles Black. 1899.

free bleeding from the artery into the pericardial sac. In two cases of poisoning, one by carbolic, and in the appeared in the *Veterinarian*, and the *Zoologist*, but part I. gives a capital summary of the author's results and beliefs. Many interesting questions are discussed, and the author shows how far his experiments throw light on them; thus he only admits prepotency as occurring by the parent of the purest descent having the greatest influence. Telegony, according to the present state of the author's mind, occurs but seldom, if at all. The many problems of Reversion are fully discussed, and striking examples are given. The book is fully and well illustrated, and will be found interesting reading.

To those who have opportunity of trying experiments in crossing, it will have further interest, as it lays down profitable lines of investigation, which, if pursued by many, will lead in a few years to an accumulation of collective experiment, which will finally clear up many doubtful points.

THE NEW ENGLISH DICTIONARY.

THE double section of the New English Dictionary, just to hand, finishes the letter H, and, with it, the first half of Volume V. It contains 2,721 main words, 528 special combinations explained under these, and 467 subordinate entries, 3,716 in all.

Comparison with the corresponding pages of some other lexicographical works shows the following figures:—Words recorded, Johnson 403, Cassells 1,939, Century 2,713, Funk 2,816, Here 4,371. Words illustrated by quotations, Johnson 294, Cassells 459, Century 894, Funk 267, Here 3,290.

Number of illustrative quotations, Johnson 930, Richardson 998, Cassells 655, Century 1,980, Funk 332, Here 15,160. The total number of quotations in H reach the enormous number of 59,776, for the letter the "Century" Dictionary gives 8,349.

Among the substantives in this section are the names of three important bodily members, hand, head, heart, which, with their derivatives, occupy 109 columns, and show how the designations of prominent parts of the body lend themselves to all manner of figurative and transferred applications, and to a luxuriant growth of phrases.

Medical News.

The Etymology of "Drug."

A contributor to the *Chemist and Druggist* discusses the etymology of the word drug. The generally accepted derivation, we are told, is the Anglo-Saxon "dryge" = dry. Dr. Murray cautiously states that the ulterior origin is uncertain. The earliest quotation he gives is from the Close Roll of Edward III., 1327:—"Novem balas de drogges de spicerie." In some MSS. of Chaucer the word appears as "dragges," and this has led some etymologists to the belief that the words "drug" and "dragee" (a stomachic sweet-meat) are of similar origin. Professor Skeat, however, says "dragges" and "drogges" cannot be the same word. Littré, following most continental authorities, says that the French "drogue," and the Spanish "droga," come from the Dutch "droog" or "droom," which also means dry. Some authorities explain that this etymology is based on the fact that a drug was generally a dried herb, while it has also been guessed that a drug was so called because it dried up and cleansed the body, affording no nourishment. A more plausible explanation is that the word "drug" is a descendant of Cymric "drwg," old Irish, "droch," signifying something that is bad. This idea is worked out in Larousse's "Grand Dictionnaire Universel." The word would thus be associated with the almost invariably nasty taste of medicines. The Celtic "drwg" would probably, he thinks, be related to the Sanscrit "drubh," which is applied in the Rigveda to a maleficent demon. Demons under this or similar names are traceable in many Eastern folklore tales, and the Irish had a dwarf evil

spirit, which was known as a "droich." The connection of the word "drug" with this meaning, something nasty and common, would go some way towards explaining the very ancient use of the word as something not wanted, as when we speak of "a drug in the market," and it might probably help to understand its application to a common sort of carpet, called a "dragget," which some authorities with no sort of historical evidence have associated with the town of Drogheda.

London Hospital Medical College.

THE following entrance scholarships have been awarded:—Price Scholarship in Science, value £120, Mr. R. Milne. Price Scholarship in Anatomy and Physiology, for Oxford and Cambridge students only, value £80, Mr. A. W. S. Fisher. Entrance Scholarships, value £47 10s. each, Mr. G. A. Soltau and Mr. T. W. Smith (equal).

St. Thomas's Hospital Medical School.

THE prizes were distributed at this hospital yesterday (Tuesday) by Dr. T. Clifford Allbutt, F.R.S., at the opening of the School for the winter session. The successful competitors for the past winter session:—

Entrance Science Scholarships.—C. M. Roberts, First Scholarship, £150, and C. H. Latham, Scholarship, £80.

First Year's Students.—G. C. Adeney, the Wm. Tite Scholarship, £27 10s.; C. M. Roberts, College Prize, £20; C. H. Latham, College Prize, £10.

Second Year's Students.—C. U. Ind, the Musgrove Scholarship, £38 10s.; W. H. Harwood-Yarred, College prize, £20; J. E. Adams, College prize, £10.

Third Year's Students.—C. N. Sears, College prize, £20, and 2nd tenure of Peacock Scholarship, and A. F. Miskin, College prize, £15.

The following were the prize winners for the past summer session:—

First Year's Students.—F. W. W. Smith, College Prize, £15, and C. M. Roberts, College Prize, £10.

Second Year's Students.—C. U. Ind, College Prize, £15, and H. W. Sexton, College Prize, £10.

The following were medalists:—

R. J. Horton Smith, the Wainwright Prize in Practical Medicine.

H. T. D. Acland, the Cheselden Medal, in Surgery and Surgical Anatomy.

H. D. Singer, the Bristowe Medal, in Pathology and Morbid Anatomy.

J. Gaff, the Treasurer's Gold Medal, for General Proficiency and Good Conduct.

In addition to the foregoing several students received "Certificates of Honour" for excellent work done, including those who had filled house appointments during the past year.

Middlesex Hospital Medical School.

THE Entrance Scholarships at the Middlesex Hospital Medical School have been awarded as follows:—Freer Lucas Scholarship (135 gs.), Leonard Herbert Henry Bays, Epsom College; First Entrance Scholarship (£100), F. Wood; Second Entrance Scholarship (£80), W. Kingsbury; Entrance Exhibition (£25), Raoul Felix, Mauritius; University Scholarship (£80), A. E. Taylor, Downing College, Cambridge; *proxime accessit*, Louis Courtauld, Trinity College, Cambridge.

Life Assurance Congress.

A CONGRESS of medical men interested in examinations for life assurance was held last week at Brussels under the presidency of the Minister of Agriculture, Mr. Van der Bruggen. Recent legislation in respect of injuries to workmen has given rise to a large number of interesting questions, and one of the results of the meeting will be an endeavour to codify rules concerning the risks to life and accident assurance companies for general use. We hope to be able to give a synopsis of the transactions at an early date.

The Mortality of Foreign Cities.

THE following are the latest official returns, and represent the last weekly death-rate per 1,000 of several of the populations:—Calcutta 25, Bombay 48, Madras 34, Paris 15, Brussels —, Amsterdam 13, Rotterdam 17, the Hague

21, Copenhagen 20, Stockholm 16, Christiania 16, St. Petersburg 22, Moscow 25, Berlin —, Hamburg 18, Dresden 20, Breslau 27, Munich 23, Vienna 15, Prague 22, Buda-Pesth 17, Trieste 28, Rome 1, 2 Turin —, Venice 19, Cairo —, Alexandria —, New York 18, and Philadelphia 13.

SUBG.-LIEUT. ANTHONY has command of a large force of the Royal Army Medical Corps which is being concentrated at Portsmouth in view of the probability of war with the Transvaal. This corps will furnish the general hospital in the field, and also a detachment for service on the hospital ship.

Tropical Medicine.

THE first winter session of the new School of Tropical Medicine, recently established in connection with the Seamen's Hospital, was inaugurated on Monday last by an address delivered by Dr. Patrick Manson. Instruction in this special class of disease will be given both in the lecture theatres and in the hospitals of the Seamen's Hospital Society.

A Valuable Medical Appointment.

A recent recommendation of the Local Government Board to the Glossop Guardians that they should pay for the more expensive medicines, and not throw the cost on the Medical Officer, elicited the statement from that officer that, out of a gross salary of £50 he had to pay out £25 to £30 for such medicines. The Glossop Guardians are to be congratulated on the possession of so conscientious an official. When paupers' drugs for an entire union, and for a year, have to be paid for out of such a pittance as £50, it seems probable that they would not be of the rarest or most efficacious quality.

University Education in France.

THE official report of the French Government states that the total expenditure of the fifteen universities for the year was 13,859,500 francs, for which sum they educated 27,080 students—i.e., 511 francs, or nearly £20 per student. The united income of the universities is about 3,600,000 francs, so that ten million and a half francs have to be found by the State as a subsidy.

Vital Statistics.

THE deaths registered last week in thirty-six great towns of England and Wales corresponded to an annual rate of 20·6 per 1,000 of their aggregate population, which is estimated at 12,786,832 persons in the middle of this year. The deaths registered in each of the last four weeks in the several towns, alphabetically arranged, corresponded to the following annual rates per 1,000:—

Birkenhead 25, Birmingham 22, Blackburn 21, Bolton 22, Bradford 17, Brighton 16, Bristol 14, Burnley 26, Cardiff 16, Croydon 15, Derby 15, Dublin 29, Edinburgh 19, Glasgow 21, Gateshead 26, Halifax 15, Huddersfield 10, Hull 21, Leeds 21, Leicester 16, Liverpool 27, London 18, Manchester 26, Newcastle-on-Tyne 27, Norwich 17, Nottingham 22, Oldham 16, Plymouth 17, Portsmouth 19, Preston 23, Salford 27, Sheffield 26, Sunderland 28, Swansea 8, West Ham 21, Wolverhampton 14. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From measles, 1·4 in Burnley; from fever, 1·1 in Nottingham, 1·6 in Sheffield, and 2·5 in Portsmouth; from diarrhoea, 4·4 in Nottingham, 4·7 in Birmingham, 6·0 in Hull, 6·4 in Bolton and in Manchester, 6·8 in Sunderland, and 8·0 in Preston. In none of the large towns did the death-rate from scarlet fever or from whooping cough reach 1·0 per 1,000. The 89 deaths from diphtheria included 42 in London, 11 in Sheffield, 8 in Leicester, 5 in Liverpool, 3 in Leeds. Three deaths from small-pox were registered in Hull, but not one in any other part of the United Kingdom.

Adolescence and Longevity.

THE *Leisure Hour* for October contains some interesting statistics regarding the duration of life, from which we quote the following:—"Dr. Ainslie Hollis has recently directed attention to the connection between the times which man and various animals take to arrive at maturity and the duration of their natural life, assuming that death occurs by senile decay. It appears that the period of adolescence is less in proportion to the full

term of life in the case of short-lived mammals than it is in those with longer lives. For instance, a mouse arrives at maturity in about three months, and the length of its subsequent life is four years, or about fifteen times the period of adolescence; a horse arrives at maturity in eight years; its natural length of life afterwards is about four times this period; man completes his full growth at the age of twenty-five years, and the expectation of life beyond this is twice the period of adolescence. The length of the period of man's youth is thus greater in proportion to the whole length of life than that of animals with shorter lives. The relation between adolescence and longevity is so close that Mr. E. D. Bell has shown that it can be expressed by a mathematical formula, namely, 'The full term of life in a mammalian species is equal to ten and a half times the period of maturity divided by the cube root of the period of maturity.' This statement, of course, simply represents an average, and takes no account of death by accident or disease."

PASS LISTS.

University of Durham.

The following candidates passed the third examination for the degree of Bachelor in Medicine during September:—

Honours—Second-class.

Thorne-Thorne, Richard, St. Bartholomew's Hospital.
Bodman, Christopher Osmond, University College, Bristol.
Hindmarch, Robert Simpson, College of Medicine, Newcastle.
Reah, Henry, College of Medicine, Newcastle.
Parkin, Alfred, College of Medicine, Newcastle.

Pass List.

Adeniyi-Jones, Curtis Crispin, College of Medicine, Newcastle.
Appley, Ernest Bertram, College of Medicine, Newcastle.
Clarkson, Frederick, St. Thomas' Hospital.
Coates, Thomas Seymour, College of Medicine, Newcastle.
Gibson, Charles Henry, College of Medicine, Newcastle.
Hawes, Ivon Henry Skipwith, St. George's Hospital.
Hodge, Albert Ernest, College of Medicine, Newcastle.
Horan, Hubert Wolstenholme, College of Medicine, Newcastle.
Manson, Kenred, College of Medicine, Newcastle.
Scott, Frederick Riddle, College of Medicine, Newcastle.
Vaux, Ralph Thomas, College of Medicine, Newcastle.
Velenski, John Charles, College of Medicine, Newcastle.

The following Degrees were conferred on September 23rd, 1899:—
Doctor in Medicine:—John Charles Anderson, M.B., Dur.; Arthur James Dale, M.B., B.S., Dur.; J. Livingstone Frazer-Hurst, B.A., M.B., B.S., Dur.; Ralph Norman Lishman, M.B., B.S., Dur.; Theodor Lund, M.B., B.S., Dur. (*in absentia*); Norman McCall-Smith, M.B., B.S., Dur.; William L. Wight Walker, M.B., B.S., Dur.; William Henry Whitehouse, M.B., B.S., Dur.

Doctor in Medicine (Practitioners of Fifteen Years' Standing):—Oswald Baker, L.R.C.P. and S.; E.; Ralph Henry Browne, M.R.C.S., L.R.C.P.; William G. Dickinson, M.R.C.S., L.R.C.P., D.P.H.; Dennis Cawood Embleton, M.R.C.S., L.R.C.P.; Syed Hassan, M.R.C.S., L.R.C.P., D.P.H.; H. Nelson Halberton, M.R.C.S., L.R.C.P., D.P.H.; Joseph Stenson Hooker, L.R.C.P. and S.; E., L.S.A.; John C. Radcliffe Husband, M.R.C.S., L.R.C.P.; Henry Knowles, L.R.C.P., L., L.R.C.S., E.; Henry Richard Leach, L.R.C.P. and S.; E., L.S.A.; Gordon B. Willie Messum, M.R.C.S., L.R.C.P.; George Sinclair, L.R.C.P. and S.; E.; Thomas Hanson Smith, L.R.C.P. and S.; E.; Henry George Sworn, M.R.C.S., L.R.C.P.; John Arthur Webster, M.R.C.S., L.S.A.; Neville Thorold Wood, M.R.C.P., L.R.C.P., M.R.C.S.

Bachelor in Medicine (M.B.):—Norman Christian Bailes, Laurence James Blandford, Mark Francis Cahill, L.R.C.P., L.R.C.S.; Solomon Cross; Harold Ben Fawcus; Richard Fisher, M.R.C.S., L.R.C.P.; Edward Goffton; Robert Bond Greaves, L.S.A.; John Butherford Halliday; William John Harrison; William Hayward, M.R.C.S., L.R.C.P.; John Tyrer Johnson; Henry Herbert Markham; Richard Oswald Mather, L.R.C.P.; James Muirhead; Edward Frederick Pratt, L.R.C.P.; Morgan Richards, L.S.A.; Norcliffe Roberts; Robert Lewis Routledge; Edward Norman Threlfall; Carl Wahlgren Von Bergen; David Henderson Weir.

Bachelor in Surgery (B.S.):—Norman Christian Bailes, Laurence James Blandford, Solomon Cross, Harold Ben Fawcus, Richard D. Fisher, M.R.C.S., L.R.C.P., Leopold Fothergill, M.B., Edward Goffton, Robert Bond Greaves, L.S.A., William John Harrison, William C. Hayward, M.R.C.S., L.R.C.P., John Tyrer Johnson, Henry Herbert Markham, James Muirhead, Edward Frederick Pratt, L.R.C.P., Morgan Richards, L.S.A., Norcliffe Roberts, Robert Lewis Routledge, Edward Norman Threlfall, Carl Wahlgren Von Bergen, David Henderson Weir.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or

initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

HARD ON THE CHEMIST.

BANGS: "I'd give a good deal to know how it feels to be drugged and robbed."

Benthere: "Why don't you go and get a prescription made up at Messrs. X and Y?"

G. S. T.—We cannot tell without seeing our correspondent's MS. whether the article will be suitable for our columns or not.

POISONING BY MISADVENTURE.

THE unfortunate mistake of Dr. Dick at Eastbourne, which a few days ago cost him his life, has brought us more than one inquiry about poison bottles and safety stoppers. It appears that the ingenuity of manufacturers is of no avail, and that the majority of practitioners still store the most deadly poisons in ordinary bottles, notwithstanding the frequent fatal accidents occasioned thereby. For the information of our correspondents we may state that there is no lack of protective material always at hand. But a few months since we drew attention to an ingenious poison bottle made at Hearn's Glass Works, Lea Bridge, London, N.E., costing but a few pence, and of such a shape that a mistake would be impossible in the hurry of compounding or even in the dark. As an alternative we have a safety stopper, made by Messrs. Foster and Crowley, which is provided with a prickly cap at the top of the cork, giving a sharp reminder of danger. There are many other devices, but these happen to be before us and may be pronounced absolute safeguards.

M. R. C. S. (Leeds).—We cannot recommend our correspondent to adopt the course which he proposes to take. We are writing to him privately.

DR. S.—Application must be made direct to the Colonial Office. Further information will be found in our "Students'" number, published on the 13th of last month. A copy can be obtained from the publisher.

P. S. D. (Manchester).—From an ethical point of view our correspondent acted quite rightly.

L. R. C. S. Edin. (Bradford).—It is usual for a consultant to write after seeing the patient sent for consultation, giving a detailed account of the case to the practitioner.

M. D.—Our correspondent should write to the Dean, West London Postgraduate College, West London Hospital, Hammersmith, W.

SURGEON.—The subject has only recently been discussed in our columns, but we will shortly again deal with it and draw attention to the facts brought under notice by our correspondent.

THE VALUE OF PETROLEUM EMULSION IN THE MORPHINE HABIT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Incases of enforced administration of morphine there is generally trouble with the bowels. In these cases I have almost ceased the administration of powerful tonic drugs such as atropine and nuxvomica, and prescribed petroleum emulsion with much success. Thinking this fact may be useful to others who have to deal with similar cases, I should be glad if you will kindly draw their attention to the points at issue through your valuable columns.

I am, Sir, yours truly,
PERCY G. LODGE.

100, Preston Street, Bradford, Oct. 2nd, 1899.

ERRATUM.—In the letter of Mr. Corbett upon the Lunacy Question in our issue of the 27th ult., the number of insane in the three kingdoms was, by a printer's error, stated as 240,000 instead of 140,000. The actual figure was 139,700.

OMEGA.—The subject is referred to in our editorial columns.

Meetings of the Societies and Lectures.

WEDNESDAY, OCTOBER 4TH.

OBSTETRICAL SOCIETY OF LONDON.—8 p.m. Specimens will be shown by the President, Dr. W. Duncan, and others. Papers:—Dr. Williamson: The Pathology and Symptoms of Hydatidiform Degeneration of the Chorion.—Dr. Herman: Two Cases in which Life appeared to have been Saved by Anti-Streptococcic Serum.

FRIDAY, OCTOBER 6TH.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich Road, S.E.) 8.45 p.m. Annual Business Meeting. Clinical Cases by Dr. Toogood, Dr. Dockrell, Mr. Clarke. Dr. Sunderland, and Mr. Parke.

Vacancies.

Cumberland and Westmoreland Asylum, Garlands, Carlisle.—Junior Assistant Medical Officer, unmarried. Salary £100 a year, with board and residence.

Durham County Asylum, Winterton, Ferryhill.—Assistant Medical Officer, unmarried. Salary commencing at £140, with board, lodging, washing, and attendance.

Egyptian Government School of Medicine, Cairo.—Professor of Ophthalmology. Particulars from F. G. Hallett, Esq., Secretary, Examination Hall, Victoria Embankment, London.—(See advert.)

Essex and Colchester General Hospital, Colchester.—House Surgeon. Salary £100 per annum, with board, washing and residence in the hospital.

Hospital for the Insane, the Coppice, Nottingham.—Assistant

Medical Officer, unmarried. Salary £150 per annum, with apartments, board, attendance, and washing.

Hospital for Women and Children, Leeds.—Non-resident House Surgeon for six months. Salary at the rate of £125 per annum. Leicestershire and Rutland Lunatic Asylum.—Assistant Medical Officer, unmarried. Salary commencing at £150, with board, lodging, washing and attendance. Applications to the Clerk, 10, New Street, Leicester.

Loughborough and District General Hospital and Dispensary, Loughborough.—Resident House Surgeon. Salary £100 per annum, with furnished rooms, attendance, and board.

Parish of Fulham, London.—Medical Superintendent of the Infirmary and Medical Officer of the Workhouse. Salary £300 per annum, with residence, (partly furnished), fuel, lights, and washing.—Applications to the Clerk to the Guardians, 75, Fulham Palace Road, W.

Royal Infirmary, Hull.—Senior House Surgeon for two years, unmarried. Salary 100 guineas per annum, with board and furnished apartments.

West Riding Asylum, Wakefield.—Fifth Assistant Medical Officer. Salary £100 per annum, rising £10 annually to £150, with furnished apartments, board, washing, and attendance.

Workshop, Notts.—Medical Officer at the Workshop Dispensary, unmarried. Salary £120 per annum, with house, coals, gas, and attendance.

Appointments.

BAKER, W. J. T., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., Medical Officer for the South Sanitary District of the Sheffield Union.

BOVEY, THOS. W. W., L.R.C.P. Lond., M.R.C.S., Medical Officer for the Abbotsbury District of the Weymouth Union.

DUFF, J., M.D. Glasg., M.R.C.P. Lond., Medical Officer for the Infectious Hospital, Chester.

FRENCH, E. G., M.B., Ch.B. Edin., House Surgeon to the Royal Alexandra Hospital, Brighton.

JELLETT, J. C., L.R.C.P., L.R.C.S. Irel., Medical Officer *pro tem.* for the Cranbrook and Frittenden Sanitary Districts of the Cranbrook Union.

KELYNACK, T. N., M.D. Vict., M.R.C.P. Lond., Medical Registrar to the Manchester Royal Infirmary.

LOXTON, ARTHUR, F.R.C.S. Edin., Honorary Surgeon to the Birmingham and Midland Hospital for Skin and Urinary Diseases.

RICHMOND, R. T., M.A. Cantab., M.R.C.S., L.R.C.P. Lond., House Physician to the Royal Hants County Hospital, Winchester.

TAYLOR, G. G. S., M.D. Durh., L.R.C.P. Irel., M.R.C.S., Honorary Physician to the New Hospital for Cancer and Skin Diseases, Liverpool.

Births.

GALLOWAY.—On Oct. 1st, at 54 Harley Street, London, W., the wife of James Galloway, M.D., F.R.C.P., of a daughter.

LAYTON.—On Sept. 30th, at The Lawn, Walsall, Staffs., the wife of Frank G. Layton, M.R.C.S., L.R.C.P., of a daughter.

WALLIS.—On Sept. 29th, at 237 Roman Road, Old Ford, Essex, the wife of Sidney S. Wallis, L.R.C.P., M.R.C.S., of a son.

Marriages.

MATBURY—WAGNER.—On Sept. 27th, at St. James's Church, Weybridge, Lysander Maybury, M.D., of Southsea, son of the late N. A. Maybury, M.R.C.S., of Finchley, to Ethel, daughter of O. H. Wagner, of Wimbledon.

MARSH—CREW.—On Sept. 27th, at Prestbury Church, John Hedley Marsh, M.R.C.S., L.R.C.P. Lond., Medical Officer of Health for Macclesfield, to Florence May, youngest daughter of Thomas Crew, Macclesfield.

ROUSE—HAWKINS.—On Sept. 27th, at St. Paul's Church, Worthing, Algernon Edward Rouse, M.R.C.S. Eng., L.R.C.P. Lond., of Littleport, third son of the late James Rouse, F.R.C.S., of London, to Florence Edith Hawkins, third daughter of the late Edward Hawkins, of Hampstead.

STONER HALL.—On Sept. 26th, at the Parish Church, Brighton, Harold Stoner, M.R.C.S., L.R.C.P., L.D.S. Eng., of Regency Square, Brighton, to Ethel Mary, second daughter of Edwin Penfold Hall, of Grand Parade, Brighton.

SUTHERLAND—GAIRDNER.—On Sept. 28th, at the University of Glasgow, Lewis Robertson Sutherland, M.D., Professor of Pathology in the University of St. Andrews, to Helen Christian, elder daughter of Sir William Gairdner, K.C.B., Professor of Medicine in the University of Glasgow.

THOMAS—DUNCANSON.—On Sept. 28th, at the Congregational Church, Bromley, Kent, Harold Wynne Thomas, M.R.C.S. Eng., L.R.C.P. Lond., of Bromley, to Madeline Forrester, twin daughter of the late E. F. Duncanson, of Nutwood, Bickley.

Deaths.

JACKSON.—On Oct. 1st, at 94 Broadhurst Gardens, South Hampstead, Henry E. Jackson, M.R.C.S., aged 52 years.

KING.—On Sept. 23rd, at Chepstow, Edward Pendril King, M.R.C.S., L.S.A., son of the late Thomas King, F.R.C.S., of Chepstow, aged 64 years.

SHURLOCK.—On Sept. 27th, at Eldridges, Chertsey, Manwaring Shurlock, M.R.C.S., L.S.A., aged 85.

WALLACE.—On Oct. 1st, at 1, St. John's Terrace, Colchester, Alexander Wallace, M.D. Oxon, M.R.C.P. Lond., aged 70 years.

THE QUEST OF THE IDEAL. (a)

By SIR JAMES CRICHTON BROWNE, F.R.S.

AFTER comparing the Manchester of to-day with the Manchester of a century ago, the city described by de Quincy as "mud below and smoke above," the author reviewed the history of the institution, and contrasted the sums, with difficulty raised to further the cause of medical education with those so lavishly bestowed on accommodation for lunatics.

Passing on to the oration proper, he said that in considering how he could best achieve an introductory address which would be stimulating rather than instructive, that should stir one or two present to more vigorous endeavour in the work before them, it had occurred to him to warn them against certain dangers which would assuredly beset their path, dangers not generally realised, but real enough. The dangers he referred to were not ethical, but mainly intellectual. He desired to speak merely as one who had gone before along the road they were about to travel, who was familiar with its windings, and able to caution them against certain tendencies which were incidental to the route, and which sometimes were lamentable and disastrous in their results. He alluded to these modern tendencies to materialism, which regarded mind as a mode of motion, or to its congener, naturalism, which subordinated spirit to mechanism and set up unchangeable law as supreme, the agnosticism which ignored both mind and matter and confined its attention to phenomena, tendencies the influence of which they were certain to feel, and to which some of them were not unlikely to succumb. Their teachers could supply them with no corrective to the materialising agencies which would operate upon them in the laboratories and the hospitals, but then they had no antidote to the materialistic virus, the great catholic teachers to whom all who are interested in medical and biological science were obliged sooner or later to turn, would inject it into their veins with tenfold virulence. Herbert Spencer was certainly responsible for the widespread diffusion of materialism. The splendid cogency of his arguments with regard to the whole phenomena of the universe had obtained for his theories as to the evolution of mind—which, notwithstanding his admission of an unknowable as a necessary datum of consciousness, were pure and undiluted materialism—such ready currency. Spencer insisted that mind arose out of the molecular vibrations of matter, just as do light, heat, and electricity, and that the only difference between the commonest sensation and the most transcendent emotion lay in the number and complexity of the molecular vibrations of nerve surface. He did this with a subtlety and ingenuity that almost inevitably

commanded the assent of those whose daily experiences impressed them with the constant and intimate connection between brain states and mental manifestations, and so his philosophy had dashed to pieces the ideals of many medical postulants. If Spencer had done much to scatter broadcast materialistic ideas in medical circles, Huxley had done more, for in spite of his repudiation of the title materialist as a reflection on his agnostic orthodoxy, few recent writers better deserved the designation. He had taught that molecular changes in the brain were the causes of all states of consciousness, voluntary acts being as purely mechanical as reflex action. High thinking, in his alembic, turned out to be merely increased resistance and friction in certain nerve circuits. He had reduced our species to conscious automata.

The ways by which materialism was avoided and faith reconciled with science were many. Sometimes it was not reconciliation, but cohabitation, that was arrived at, as in the cases of Faraday and Cuvier. The victory of science over faith was sometimes the advent of peace. There were those again to whom an expectant attitude afforded composure. The loss of the ideal was a personal calamity. "That way madness lies," as those engaged in his own special department of practice were not seldom made aware, and the loss of the ideal was inevitable if no solution of the world problem could be arrived at, or if the solution were materialism. Materialism reduced all things to the pull of opposing atoms. Under its interpretation intellect was the activity of nerve cells; immortality a delusion; virtue, honour, duty, were forms of selfishness; and heroism a kind of disease. When that glorious woman, the stewardess of the *Stella*, took off her lifebelt and gave it to an affrighted being beside her, and bravely sank, commending her soul to God, her act was not conducive to the preservation of the individual or the special. It was an expression, we were told, of the abnormal overfunctioning of a certain portion of her brain. Did not the heart sink and the gorge rise at such revolting nonsense?

It was not for him in the time at his disposal to combat those three formidable giants who were always lying in wait to devour medical students—materialism, naturalism, and agnosticism. What he had to say was simply an exhortation to hold fast, as their sure refuge, by idealism, which, in one shape or another, and however smothered up, still dwelt in each of them, and with this exhortation he would associate a suggestion that the assumptions of science which excluded an idealistic view of the world, as well as the prepossessions against anything beyond solid facts and their material explanations, which their studies might have engendered in their minds, were still open to doubt and refutation. Wide as was the sphere of science, it was still limited in all directions. As Max Muller said:—"Our minds are not so made as to grasp either beginnings or ends." The range of the senses was a narrow one. Beyond the red and

(a) Introductory Address delivered at the Opening of the Winter Session of Owen's College, Manchester, October, 1899.

violet of the spectrum were rays of wave lengths to which the retina did not respond. Hearing held good only from thirty up to 40,000 vibrations a second, and smell, taste and touch, went but little way in revealing the properties of matter. It was certain that what we called our intellect rested on belief and not upon knowledge. Physical science could do nothing to demonstrate the existence of an outer material world, which we believed in, nevertheless; physical science could never prove the existence of mind in our fellow men, yet it was one of our most rooted beliefs. He desired to draw attention to certain unfathomable chasms that yawned well within the bounds of recognised science, and the existence of which was inconsistent with the materialistic hypothesis. First there was the chasm between the organic and the inorganic. Secondly, there was the chasm between the physical and the vital, for if the origin of life was wrapped in obscurity, so was its maintenance. Thirdly, there was the chasm—the widest of all and the most fatal to materialism—between mind and matter. It was just this chasm, which, as young medical scientists, they were likely to overlook, for the dependence of the mind upon the brain was a pre-supposition of much of their work. No man had seen thought at any time, and no man had seen neural process. It was only in their effects that we could follow them from point to point, i.e., in sensation and movement. Thus it was that Du Bois Raymond had said it was hopeless to resolve thought into a physiological process, and that Wundt had delivered himself to the effect that the action of mind on matter, if it existed, would be in the nature of a miracle. Thus it was that modern science had repudiated crude materialism as regards the relations of mind and brain, and had fallen back on an agnostic theory called psycho-physical parallelism, which was now in the ascendant. This theory avoided a shallow materialism by propounding an enigma, but in spite of its professions of the equality of the psychical changes and their physical counterparts, it very soon appears that those who adopt it give precedence to matter.

After a detailed dissertation on the structure of the brain, Sir James said mind and character in health and disease were to be appraised by the reactions which a man's words and deeds had on our minds. They could not be made visible or palpable to the outer senses, but through their body mask they might be discerned clearly enough by the light which our own minds reflected on them. "Suppose," said Professor James, "that the whole universe of material things should prove a mere surface veil of phenomena, hiding and keeping back the world of genuine realities. Suppose that our brains are thin or transparent places in the veil, through which gleams from the outer sunlight of absolute light may shine; is it not clear that the light will break through our brains in the restricted forms, and with all the imperfections that characterise the medium of transmission?"

"Brain, like a dome of many coloured glass
Stains the white radiance of eternity."

It was not any abstract psychological system—invaluable though that may be in its own sphere—that interested them as medical men, but the real life and its ideal element; and his firm belief was that their professional success would largely depend on the manner in which they combined realism with idealism. About their realistic fidelity there could be no doubt; it was for their adherence to the ideal that he pleaded. How was the ideal, whether it was in the mind innately or had been won by sore travail, to be fostered and nourished and kept alive? By all those observances and ordinances that the wisdom of ages had consecrated, and that in these hurried and luxurious days we were apt to neglect. By the assumption of

an attitude of reverence and sympathy, which would incline our ear to the whisperings of the infinite, and afford us glimpses of the inner impulses by which other men shaped their lives. By the practice of the manly discipline of self-renunciation for which their profession afforded the finest scope; for in ministering to the wants of others, even at the sacrifice of their own, they could mount to blessedness. He could express no better wish for them than that while immersed in the realities of life they might be rewarded in their quest of the ideal, for it was a talisman that, once seized and pressed to the breast, would enable them to say to pessimism "Avant!" and to beneficence "Open Sesame!" Negation was a barren wilderness, belief a teeming garden. Lord Byron said he would rather believe all the fables of the Talmud or the Koran than deny the being of the Universal Mind, and Newton concluded his *Principia* with these words: "The whole diversity of natural things can have arisen from nothing but the ideas and will of one necessarily existing being who is always and everywhere, God, supreme, infinite, omnipotent, universal, absolutely perfect."

CHANGES IN THE MEDICAL PROFESSION DURING THE PRESENT CENTURY.

Abstract of Presidential Address delivered at the Inaugural Meeting of the 127th Session of the Medical Society of London on Monday, October 9th, 1899.

By FREDERICK T. ROBERTS, M.D.,
F.R.C.P., LOND.,

Professor of Medicine in University College, London. Physician to and Professor of Clinical Medicine in University College Hospital, &c.

DR. ROBERTS remarked at the outset that it would be almost impossible for anyone who had to give an address at the present time on an occasion such as this to resist taking as his text, from some aspect or other, the century now so rapidly drawing to a close. As President of the Medical Society of London, it would be inhuman to expect him, at the inaugural meeting of the last session in the century, not to take advantage of such an opportunity for selecting a topic at hand, and he therefore proposed to indicate, on very general lines, the more striking changes which had affected the medical profession during the present century and the main results, in the direction of progress, which had been achieved.

After a personal reference to the fact that he had been associated with the profession for nearly the latter half of the century, from the time when he first started as an apprentice, the lecturer made some observations on the apprenticeship system, the doing away with which was a most important change. He could not allow the century to close over its grave without a parting word of kindly appreciation. He had never regretted that it had fallen to his lot to pass through this experience, and acknowledged with gratitude that the practical lessons impressed upon his mind at that time not only helped him as a student but had served him in good stead on many and many an occasion.

Passing to the discussion of his special subjects, Dr. Roberts assumed that he was echoing the sentiments of his hearers when he affirmed that the medical profession had made vast strides in the direction of true progress during the past century, especially its latter half, in spite of what carping and unfriendly critics might say to the contrary. He then proceeded to indicate, briefly, the means or agencies by which this had been brought about. He dealt, in the first place, with the advance in general education

and culture, and the establishment of a comprehensive and rational system of compulsory professional education and training, and its progressive development on scientific and practical lines, including clinical teaching, in accordance with the requirements of the age. He laid special stress on the adoption of the scientific spirit and of scientific methods in the study and teaching of medical subjects, as well as the introduction into the curriculum of allied subjects more strictly scientific, and the promotion of their methodical and deeper study. He also drew attention to the great advantages derived from the separation or unravelling of subjects which, though essentially distinct, were formerly, if dealt with at all, included under one term, and discussed in a single course of lectures; and the addition of new subjects, the outcome of increasing knowledge. Referring in this connection to "specialism," Dr. Roberts expressed his opinion "that to this comparatively modern development, the progress of medicine owes more than can be imagined or expressed in words, and that when carried out legitimately and rationally, it has proved, and always will prove, of infinite advantage to the profession and to humanity. It is its abuse which works such serious mischief, and against which we must ever protest."

The lecturer next spoke about the influence of examinations upon medical progress, and claimed that though still unsatisfactory, they had certain advantages, and had contributed materially to the general advance. He referred at some length to the institutions which have been concerned with and responsible for the important departments of medical education and examinations. In this connection he drew attention to a significant change affecting the profession during this century, namely, the admission of "lady doctors" into its ranks, who had now a "school" of their own, where their students were admirably trained. He also complimented the provincial medical schools on the excellent work they have done and are doing; and expressed his personal satisfaction that more liberal ideas had at length prevailed at the older English universities, and that they now open their doors to all comers, while joining heartily in the promotion of medical education and science. He then continued, "Of all the agencies which have contributed to the advance of medicine none have been more conspicuous or potent than the general recognition of the essential value and far-reaching importance of original investigation and research, in a variety of directions, especially by experimental methods, and the ever-widening application of this principle as new fields of inquiry have opened up." In discussing this point he insisted upon the great debt due to vivisection in relation to practical advances in the healing art. Finally, under this head he mentioned as factors contributing to the progress of medicine during this century the remarkable increase in the number and variety of hospitals and allied institutions, and their adaptation for clinical instruction and research; the extraordinary development of medical literature of all kinds; and the opportunities for bringing before the profession the results of personal observation, experience, and investigation, and for the discussion of topics of interest or importance by the medical and kindred societies, as well as by the larger associations, and in recent times by congresses of all kinds.

Dr. Roberts then proceeded to discuss the practical results upon the medical profession arising from the changes just outlined, and the grounds upon which he rested his claim that medicine had made such material progress during the 19th century.

1. He, in the first place, emphasised the fact that he entire profession occupies an incomparably better

and higher position to-day than it has ever done before, and that the general standard of knowledge and skill has steadily risen even within recent years, until it is now remarkably high, while the great majority take a keen and intelligent interest in the march of events, exhibiting an earnest desire to keep abreast of the times and to take advantage of every new discovery which can be utilised for the benefit of their patients, whether in diagnosis or treatment.

2. He next dealt with the extraordinary advance which had been made in dispelling ignorance and establishing knowledge on a positive foundation in relation to morbid processes and conditions, as well as to individual diseases and symptoms. Amongst other points it was mentioned that complaints which were formerly included under a particular name have been shown to be distinct, and are now duly discriminated and classified; while affections which must have stared the profession in the face from time immemorial have only been definitely made out within a recent period.

3. He then spoke about the causation of disease, and insisted that one of the greatest benefits which the nineteenth century has conferred upon humanity, in relation to medicine, is the flood of light which it has thrown upon the vast field of aetiology, and the striking practical results which have been worked out in connection with this branch, not only in relation to ordinary preventive treatment, but as laying the foundation for that most important department—hygiene, sanitary science, and public health. In discussing this subject special reference was made to micro-organisms.

4. Attention was next drawn to another striking and most helpful advance, for which this century will ever be memorable, namely, the remarkable addition to, and development of, the methods of clinical investigation applicable for a variety of purposes, many of which are now regarded as so essential for arriving at a positive and correct diagnosis. Dr. Roberts remarked that the progressive development of clinical methods is a highly interesting study, culminating in that most startling revelation or outcome of modern science—the Röntgen rays—which promises to supplant all other methods, and to enable us actually to see what is going on within every part of the human body, without taking any further trouble.

Lastly, the lecturer discussed at some length the advances in treatment, referring in the first instance to his own recollections as an apprentice and subsequently, and pointing out the lines upon which progress had been established. Standing out conspicuously and pre-eminently above all others, two achievements of this century must ever be regarded with feelings of deep gratitude, wonder and admiration, namely (1) the introduction and development of anæsthetics, general and local; (2) the working out, on scientific lines, as well as on a rational and intelligent practical basis, of the great principles of antiseptic and aseptic treatment, for which we shall ever be indebted to the patient investigations and splendid work of Lister. The next line of progress in treatment dealt with was the addition to our available remedies of many genuinely useful and efficient new drugs, as well as of excellent and valuable pharmaceutical preparations and combinations. The profession cannot boast of having discovered many "cures," but not only have we at our command a far larger and increasing number of really useful medicinal agents than formerly, but we understand better how to employ both the old and the new, and for what purposes. Great improvements have also taken place in the modes of administration of therapeutic agents, the preparations and appliances intended for local purposes, and the instruments or

apparatus invented for making applications to, or otherwise treating special parts. Particular attention was drawn to the value of the hypodermic syringe in this connection.

The next important advance referred to was the recognition and adoption of the great principle of hygienic treatment, diet and nursing being also specially noted. Particular attention was then drawn to a conspicuous development of modern therapeutics, namely, the introduction or more systematic working out of "special methods," or "combinations of methods," intended either for producing some particular effect, which might be beneficial in various conditions, or for the treatment of some individual disease or class of diseases. Finally Dr. Roberts, as a physician, paid a tribute of respect and admiration to modern surgery, which has achieved such marvellous and brilliant results in a variety of directions, and has made the nineteenth century memorable for the splendid position to which it has been raised as an art.

Dr. Roberts concluded his address as follows:—"I have thus endeavoured, however imperfectly, to give some comprehensive sketch of what strikes me as the most prominent and important changes which have guided the course of the medical profession during the century which is now rapidly drawing to its close, and the lines upon which progress has taken place. I by no means wish to make ourselves out better than we are, and we must all recognise the fact, but too evident, that there are many dangers and difficulties and drawbacks in connection with our vocation, both in its internal workings and its external relationships, which cannot fail to rouse feelings of anxiety and concern as to the future in any thoughtful mind. But let us to-night be optimistic, and take a bright and hopeful view of things. The Archbishop of Canterbury recently expressed his belief 'that there could not easily be found, all the world over, a body of men who approached more nearly to the full discharge of their duty than the clergy of the Church of England.' That sentiment I unhesitatingly appropriate for the great bulk of the medical profession. And looking back upon the nineteenth century, I venture to affirm, with a feeling of assurance and pride, that their efforts during this period have contributed, in a degree which can never be adequately realized or estimated, to the saving and prolongation of life, to the cure and prevention of disease, to the eradication or great amelioration of many grave and formidable maladies, to the practical relief of human suffering, and to the promotion of the health and general well-being of the community at large.

THE PROGRESS OF RHINOLOGY. (a)

By JAMES B. BALL, M.D.,

Physician to, and Physician in charge of the Throat and Ear Department at the West London Hospital.

I PROPOSE to devote the time which the custom of the Society places at the disposal of its President at this, the first meeting of the Session, to a brief retrospect of the principal advances which have been made in rhinology, or perhaps I should say, in modern rhinology.

If we glance for a moment at the state of knowledge of diseases of the nose, which existed about the middle of the present century, we find that it was by no means inconsiderable, but diseases of the nose at this period were chiefly studied and dealt with as a branch of surgery. General medicine took little account of them. The influence of the integrity

of the nasal passages on the condition of the lower air passages and the general health, though not absolutely unknown, was scarcely ever considered. Although the grosser lesions were fairly well known there prevailed a certain amount of confusion, and a want of exactness with reference to diseases of the nasal passages, resulting from the fact that these passages were not systematically inspected. Indeed a proper inspection of them was not possible with the methods then in use. Yet without such inspection further progress was difficult. There was, however, impending, a discovery which was to open up the way for a proper inspection of the nasal cavities, and was to unfold a more exact and complete knowledge of diseases of the upper air passages than had hitherto seemed possible.

The history of the discovery of the laryngoscope has often been told, and it would be beyond my purpose to repeat it here at any length. The credit thereof unquestionably belongs to Manuel Garcia, the well-known professor of singing, who made the discovery in 1854, but the discovery of the art of inspecting the naso-pharynx and posterior nares, was made by Czermak. Already in his first communication on the laryngoscope he indicated its practicability and subsequently, in 1859, he was able to publish a full account of his method. From this date modern rhinology may be said to have begun, but it was not until 1868 that Thudichum (a member and former president of this Society) published some papers in the *Lancet* entitled "On some new methods of treating diseases of the cavities of the nose," in which he drew attention to the prevailing neglect of inspection of the nasal cavities through the nostrils. This he attributed largely to the want of a proper speculum for dilating the nares. He described the speculum which he had devised, and he advocated the use of the oxyhydrogen light for illuminating purposes, so that the author was undoubtedly one of the pioneers of rhinology in this country.

Still, the construction of a suitable speculum, or dilator, for the anterior nares by no means overcame the difficulties attending inspection of the nose from the front. The turgid mucous membrane only too often prevented a view of anything beyond the vestibule and the anterior end of the inferior turbinal. Zaufal, in 1875, introduced funnel-shaped tubes for passing into the cavities and obtaining a glimpse of deeper parts. In certain cases they afforded some help, but in 1884 a discovery was made which rendered Zaufal's funnels obsolete, and, while affording unexpected facilities for rhinoscopic examination, was destined to give an impetus to rhinology only second to that which was furnished by the introduction of the laryngoscope. This was the discovery of the effects of cocaine, first described by Freud, and utilised by Koller for the eye, and immediately afterwards by Jellinek for the nose and throat. Cocaine, which in laryngology, has afforded such valuable assistance to operative procedures, has proved of no less service to rhinology as an aid to diagnosis. By its constricting effects on the blood vessels of the mucous membrane it opens up the passages to view, rendering the deeper parts accessible to thorough exploration with the eye and probe. Its value as an anæsthetic in the performance of numerous intra-nasal operations is not to be under-rated, but still, this must rank after its value as an aid to examination of the nasal cavities. Since the introduction of cocaine the diagnosis and treatment of nasal diseases have made rapid advances, and rhinology has acquired a precision and importance not previously attainable.

With the introduction of improved methods of examination, and the increasing attention given to careful exploration of the nasal cavities, anteriorly

(a) Abstract of Presidential Address delivered before the West London Medico-Chirurgical Society on October 6, 1899.

and posteriorly, more exact knowledge of pathological conditions gradually replaced the vague ideas which had hitherto prevailed. Morbid conditions were carefully studied with the aid of the eye and the probe. Symptoms were as far as possible traced to their true pathological causes and, as each condition was identified, an appropriate and rational treatment was sought for. Many operations could be undertaken, under the guidance of the eye, and with cocaine as an anæsthetic. New and more delicate instruments were introduced, better suited to the modern method of operating under the guidance of the eye. Snarers of various kinds superseded the forceps, and the electric cautery, which Voltolini had long advocated, came into general use for many operative procedures.

The first great step in the progress of modern rhinology was the discovery of adenoid vegetations, a discovery which conferred the greatest benefit on otology and on general medicine. This important affection was first described by Meyer, of Copenhagen, in 1868. It is true that isolated instances of hypertrophy of the pharyngeal tonsil, or adenoid vegetations had been observed with the rhinoscopic mirror by Czermak, and subsequently by Loewenberg and Voltolini, but nevertheless to Meyer alone must be attributed the credit of discovering the disease. He first drew a picture of its symptoms and effects, pointed out its frequency and importance, and demonstrated the excellent results of operative treatment. The great frequency of this disease, its injurious effects on the growth and physical and mental development of children, its bearing on the etiology of ear troubles, and the satisfactory results of operation, all mark the recognition of this affection as one of the greatest steps in rhinology that has ever been made.

Although Meyer published his first account of adenoid vegetations in 1868, it took ten or twelve years before the importance of his discovery began to receive anything approaching widespread recognition. One of the direct results of this recognition was the increasing importance which became attached to free nasal respiration. All forms of impeded nasal respiration were more carefully studied, and operative methods for their relief were improved and extended. From the reiterated teachings of rhinologists, the profession generally came to appreciate the fact that, side by side with its olfactory function, the nose fulfilled still more important functions; that, in its passages, cold air was warmed, dry air moistened, dusty particles arrested, and germs of disease arrested and possibly destroyed, and, further, that the fulfilment of these functions could not be thrown on other parts without detriment. Mouth-breathing came at length to be regarded in its proper light as a diseased condition resulting from some impediment to nasal respiration, and not as a mere habit. Its ill-effects at all ages, but particularly in childhood, and the importance of timely treatment, gradually gained a more general acceptance.

Meanwhile rhinologists were becoming cognisant of the occurrence of certain disturbances in the nasal passages, as well as in distant parts, which seemed to arise in a reflex manner from nasal irritation. The recognition of a relationship between certain disturbances, chiefly of a nervous character, and nasal affections, was not altogether new, as occasional allusions to such a relationship are to be found in the older writers. Among modern writers, Voltolini was the first to point out, in 1871, the connection between nasal polypi and asthma, and B. Fraenkel shortly afterwards established a connection between other nasal affections, and asthma. The subject, however, received no great attention until the publication of Hack's observations between 1881 and 1884. It was

Hack's enthusiasm, and perhaps we may now say, his exaggerated views, which awoke the remarkable and widespread interest in the so-called reflex nasal neuroses, which manifested itself about this period. The result was that by 1890 the subject had called forth an extensive literature of its own. Besides asthma, hay fever, and certain cases of migraine and epilepsy, there was scarcely any disease the etiology of which was obscure, or the treatment unsatisfactory, that some enthusiastic rhinologist did not claim to have cured by the application of the galvano-cautery to the inferior turbinates, or by some other intra-nasal operation. Enthusiasm in a new field of treatment must beset down as an excuse for the exaggerated views and the loose reasoning which characterised many of the publications of this period. A reaction, however, soon set in, and at the present day, while rejecting much that was put forward a few years ago, we retain many solidly established facts, especially relating to the etiology of paroxysmal sneezing and hay fever, and of certain cases of cough, glottic spasm, and asthma.

Suppurative affections of the accessory sinuses of the nose, which at the present day form such an integral part of rhinological practice, received for a long time little attention at the hands of rhinologists. The earlier rhinological treatises almost completely ignored them, and the treatment of suppuration of the sinuses continued in the hands of surgeons. Of course, it was only the maxillary and frontal sinuses that there was then any question of, and the great frequency of suppurative affections of the sinuses running their course without any gross external signs was completely unknown. It was Ziem who first led the way in this department. In 1880, and subsequent years, he repeatedly demonstrated the great frequency of suppuration of the antrum, manifesting itself by a purulent discharge from the nose, and unattended by any of the classical signs which were still enumerated in most surgical works as characteristic of the disease. Ziem's observations were quickly confirmed by others, and were shown to apply equally to the other sinuses. Thus a new field of pathology, hitherto ignored, was opened up. The ethmoidal cells and sphenoidal sinus were for the first time brought within the range of diagnosis and treatment, and the frequency with which suppuration simultaneously affected several sinuses was demonstrated. In the year 1889 Heryng introduced the method of electric transillumination, a method which has proved of considerable service in the diagnosis of diseases of the accessory sinuses.

Many cases of severe and intractable headache, and neuralgia have been traced to a chronic, and otherwise very latent, suppuration of one or more of the accessory sinuses, and relief has been afforded by operative measures. The pathology of nasal polypi has received considerable elucidation from the discovery of the frequency with which these growths, especially in the most intractable cases, are symptomatic of sinus suppuration. Meanwhile, the diagnosis of suppuration of the different sinuses has attained greater precision, and great advances have been made in treatment.

It must be admitted that for some time these new branches of our art were by no means taken up warmly by physicians and surgeons. For a considerable time laryngology and rhinology were pretty generally ignored. It is safe to say that fifteen years and more after the introduction of the laryngoscope, there was not a single person connected with many of the large London teaching hospitals who could use the laryngeal or rhinoscopic mirror. It was left to the energy of private individuals to start special hospitals, and to diffuse a knowledge of these arts. But of course this state of things could not last. Gradually, but surely, the specialty asserted itself; and

departments for diseases of the throat were established first at one hospital and then at another. But meanwhile rhinology was by no means keeping pace with laryngology. Ignored by the rest of the profession, it received, too often, nothing but neglect from those who ought to have acted as its special guardians in the throat and ear departments. Nevertheless rhinology, as we have seen, has its devotees, and it was steadily compelling the attention of its sister branches. To-day its importance is generally recognised. It has taken its place side by side with laryngology and otology, indispensable to each of them, and demanding and receiving from each an equal share of attention. From them it can never be dissociated. At the same time it presents problems of its own in the fields of pathology, diagnosis, and treatment, which will only be mastered by those who devote to it the same time and attention as are given to the sister branches.

THE RELATIVE VALUE OF ANTISEPSIS AND IMPROVED TECHNIQUE, FOR THE ACTUAL RESULTS OF OPERATIVE GYNÆCOLOGY. (a)

By L. GUSTAVE RICHELOT,

Paris.

[FROM OUR OWN CORRESPONDENT.]

IT will be necessary before hazarding an opinion on the relative value of these two important points, to first examine operative results, and we have therefore to discuss 1st, The evolution of antiseptics, the part it has to play and its limitations. 2nd, The important modifications undergone by the technique in use of late years, and to point out how necessary it is to be a thorough surgeon, in order to practise surgery with success.

OPERATIVE RESULTS.

The Development of Antisepsis.—With Lister's method began the revolution, which created the possibility for future perfection in technique, but it was not flawless, and is not so yet. In the beginning, all danger was supposed to come from the air and from the invasion of wounds by atmospheric germs. Carbolic acid then reigned supreme, and this first period has been termed "empirical,"—not entirely without reason. Afterwards came a time of more exact researches into the various causes of infection and the preventive measures to be adopted. Morphological investigation and experiments *in vitro*, became the law. This was the era of scientific credulity, when nothing more was aimed at, beyond making use of the best laboratory-antiseptic for sickroom purposes.

It was not long, however, before the discovery was made, that the very best antiseptic *in vitro*, does not retain its value for clinical purposes, and that laboratory prognoses were not always to be relied upon. It was found that the use of antiseptics was not only inefficient but at times dangerous. Hence, it gradually became more or less discredited, whilst sterilisation by heat has been duly gaining favour. This brings us to the present time.

The utilisation of heat for the destruction of germs, and for sterilising instruments and dressings, originated with Pasteur, and has well nigh attained perfection; its assistance in the struggle against infection is not to be denied.

Should it be considered as a new method? It is asserted to be so, by a class of surgeons who own that antiseptics has been exchanged for asepsis. It strikes me that here must have been confusion of ideas.

Asepsis is the aim, antiseptics the way. Heat has been substituted as much as possible, for powders and solutions, but heat, in itself, is only the most powerful antiseptic. I will therefore continue speaking of the "antiseptic" method. Moreover, heat is not capable of being adapted to all purposes, and we cannot do without other antiseptics as well. It cannot be asserted that the utilisation of heat has simplified matters. On the contrary; sterilisation can only be obtained by a very complicated and expensive apparatus, demanding the most careful manipulation. It is a great mistake to suppose, as some do, that so-called asepsis, is nothing more nor less, than ordinary cleanliness; we can safely aver that the continual effort to attain asepsis by every means, has brought forth the most admirable results.

The boundary line of antiseptics must now be traced. We are enabled, to a certain extent, to prevent ourselves from carrying infection to our patients, but as personal asepsis does not destroy the existence of bacteria, we are fighting with unequal weapons against pre-existent infection. For instance, if in the course of abdominal salpingotomy, the purulent sac should burst, "contaminating the peritoneum by its contents," if the matter be particularly infectious, the patient will die, whatever may be done to avoid fatal results. It can, however, also happen that when in a similar case, the focus be carefully cleansed and drained with gauze, the patient recovers, after a few bad days. How are we to explain this? It may be that the pus was less virulent; or that the organism defended itself, no share in the recovery being due to ourselves.

This notion concerning the powers of self-defence in the organism has rectified the absolutism of the earlier ideas on the subject of micro-organisms (the specific gravity and degrees of virulency in microbes). Bacteriologists have acknowledged its importance, and shown its mechanism, by demonstrating phagocytosis. The living organism is able to defend itself, it beats off attack, when not in a debilitated condition, and armed with all its resisting-power. If this is not the case, hope is lost. We should not expect too much from "Natura medicatrix"; and when in an enfeebled condition should give it the support that is wanted. Surgical art is now called upon, and the importance of technique stands revealed. Antiseptics is the same for everyone, and demands only passive obedience to certain rules. On the contrary, techniques vary, and are subject to personal aptitude.

The value of antiseptics is, within narrow limits, absolute; the value of the techniques is relative and illimitable, it depends upon the operating hand and the directing head.

Evolution of Technique.—The great technical improvements have been rendered possible by the use of anæsthetics, exact hæmostasis and antiseptics.

Instruments.—Among the numerous inventions under this heading, that our time has produced, the greater quantity can safely be consigned to oblivion. We acknowledge the value of artery clamps and are much indebted to the Trendelenburg position, but as for the rest, we do not place too much reliance on instrumental innovations. The best results are obtained by the surgeon who knows how to use his hands and his common sense.

Surgical ability in the widest sense of the term is comprised in the three chief qualifications: dexterity, ingenuity, and judgment. Dexterity varies in its nature—some possess the gift by birth, others never acquire it, and most manage to do so, and to develop it by practice. Anyone can observe this by himself. An able surgeon operates quickly, so as to minimise the dangers of a long operation, i.e., greater chances of infection, hæmorrhage, shock, &c., although quickness of execution, should never be allowed to encroach on careful operating. The ingenuity of

(a) Paper read before the International Congress of Gynecology at Amsterdam, August, 1899

gynaecologists has opened several entrances to the pelvic organs, and taught us various methods of procedure although it must always be remembered that for methods, as for instruments, excess does not mean riches.

The history of operative treatment of pelvic diseases, fibroids, and uterine cancer, &c., shows how important is the choice of the *Operative Way*. To make sure of selecting well, we must have broad views on the subject. "Not one of us has the right to be imperfectly educated." Methods continue to become more and more simplified, and in that way lies progress. The successive extraperitoneal and intraperitoneal treatment of the stump, and total extirpations in the abdominal operations for fibroid, furnish the example. Another is found in the application of "pinces à demeure" in vaginal hysterectomy. Whatever way may be followed, which ever may be the method chosen, the *details of execution* will always decide the point. The true surgeon shows himself, who seems to be operating easily, and manages to produce the impression that anyone else could do the same.

THERAPEUTIC RESULTS.

Obviously the best methods yield the most favourable results, but it is not to demonstrate this I am now addressing you, but to speak of the relative value of antiseptics and technique—assigning to each its share in the final results. I will not select my examples among dangerous operations and merely remark that, whilst in these many operators ascribe their good results to antiseptics alone, it is the contrary for minor operations where the importance of *method* is greatly exaggerated. The question concerning abdominal suture and colporrhaphy points to the conclusion that it matters less what is done, than how.

To conclude, I wish to remark that the union of antiseptics with improved technique paves the way for conservative gynaecology, and that in this direction lies the progressive improvement we hope to attain.

Clinical Records.

ROTHERHAM HOSPITAL.

A Note on a Case of Strangulated Hernia in a Child—Death.

Under the care of Mr. LYTH.

[Reported by J. SACKVILLE MARTIN, M.B., C.M.Ed., M.R.C.S.Eng., House Surgeon.]

THE occurrence of strangulated hernia in children under 10 years of age is sufficiently uncommon to make a brief notice of such a case of interest when it occurs. In the following case the hernia was of unusual size, considering the age of the patient. The tightness of the constriction was also very marked, and was in all probability the cause of death.

A boy, *æt.* 5, was admitted to the Rotherham Hospital on August 26th, at 3.30 p.m., with a strangulated hernia in the right inguinal region. There was a history of its descent on several previous occasions, but at 10 a.m. on the morning of admission it had become strangulated and could not be reduced. Its size was considerable, being about four inches in length, from the neck to the lowest part. The child had been sick several times in the course of the morning. After a warm bath the hernia returned spontaneously into the abdominal cavity.

The child was kept at rest until the 29th. During this time he was quite well. At 1 p.m. on that date the hernia returned and again became strangulated. A warm bath, and very gentle taxis, under an anæsthetic, having failed, Mr. Lyth performed herniotomy. The sac was opened, and about eighteen inches of bowel were found in it. The bowel was congested, but lustrous, and

was returned into the abdomen. There was some omentum, which was ligatured and cut off. The whole operation did not last above ten minutes, and there was no undue handling of the intestine.

During the rest of the day the patient seemed comfortable, and the bowels moved freely on the following morning. Serious symptoms then began to show themselves. The temperature rose steadily. It was 102 degs. at 3 p.m., and rose to 105.6 degs. at 6.30 p.m. At this time the patient manifested extreme pallor and restlessness. The pulse was feeble, rapid, and irregular, the lips blanched, and the pupils widely dilated. It was thought that the condition was due to shock produced by a hæmorrhage from the omentum, from which one of the ligatures was supposed to have slipped. The patient's condition precluded any idea of further operative treatment, and in spite of the administration of opiates and the infusion of saline solution into the veins of the arm, he died at 12.30 a.m.

Post-mortem examination showed that the death was due to no flaw in the operation. The congested portion of the bowel was about one foot above the *iliæ cæcæ* valve. It was in a perfectly fit condition to justify its return to the abdomen. In the layers of the mesentery at this part, extensive extravasations of blood were found. These were due to the nipping of the mesentery at the constriction.

Death therefore was due to shock referable to the severe injury sustained by the mesentery. The soft tissues of young children do not often give rise to so severe a constriction. In looking back upon the case, it is difficult to see in what manner this particular danger could have been guarded against.

I am indebted to the kindness of Mr. Lyth, under whose care the patient was, for permission to publish these notes.

Transactions of Societies.

OBSTETRICAL SOCIETY.

MEETING HELD WEDNESDAY, OCTOBER 4th, 1899.

MR. ALBAN DORAN, F.R.C.S., President, in the Chair.

ROTATION AND IMPACTION OF A MYOMATOUS UTERUS.

MR. J. BLAND SUTTON related the case of a woman, *æt.* 35, who was seized with pain in the lower abdomen. On examination a tumour was detected in connection with the uterus, apparently a myoma, which rose above the pelvic brim, and could be felt *per vaginam*, filling the hollow of the sacrum, and occupying the left half of the pelvic cavity. Pressure on the tumour provoked great pain. A smaller tumour was felt on the right side of the pelvis also connected with the uterus. The whole mass was evidently impacted, but the cervix was free. No vesical or rectal symptoms. He operated and found the pelvis filled by a myomatous uterus, the left ovary and tube lying under the sacral promontory, and the right appendages just under the symphysis. There was no utero-vesical fossa, the peritoneum being drawn tightly over the tumour as a broad thick band. No firmly impacted was the mass that it could be withdrawn only with great difficulty. As soon as this was done the parts righted themselves so that evidently the uterus had rotated through half a circle, from right to left. As the appendages on both sides were closely adherent to the uterus he removed them and the hysterectomy was then completed without further difficulty. On section of the uterus myomata were seen to occupy the anterior and posterior walls. He suggested that as the tumours had increased in size the slow growth led to passive rotation of the large anterior tumour into the oblique diameter of the pelvis ultimately leading to impaction, rotation and pain. He remarked that it was unusual to find rotation and impaction co-existing.

TUMOUR OF THE MESOMETRIUM.

MR. BLAND SUTTON next showed a tumour which, when fresh, weighed 22 pounds removed from a woman,

æt. 43, who was admitted to the Middlesex Hospital with an indefinite and untrustworthy history. The belly was large and almost quadrilateral in shape, absolutely solid, and on auscultation a loud systolic hum was heard. *Per vaginam* the cervix was drawn up out of reach. On opening the abdomen a huge mass came into view, covered with a plexus of very large veins, projecting from the pelvis. He shelled it out of the pelvis, clamped and then divided the uterine arteries. He found the uterus so distorted as to be scarcely recognisable, so he removed it along with the right ovary and tube, having taken care to leave the pelvic portion of the capsule intact, so that after tying the vessels he was able to suture together the right and left wings thereof. The central portion in relation with the stump of the cervix and bladder was sutured to the lower angle of the incision and lightly stuffed with sterilised gauze. The operation was a severe one, but the patient bore it well. An hour later bleeding seemed to be going on into the peritoneum, so he reopened the wound, but this proved to be unnecessary. She ultimately left with the wound soundly healed in four weeks. The tumour measured thirty centimetres in diameter, and the cervix was stretched over its right side. The whole mass was hard, and was made up of spindle cells with groups of oat-shaped cells presenting patches of softening. The appearances, on the whole, suggested a slowly-growing spindle-celled sarcoma. He discussed the nature of the group of tumours classed as mesometric myomata, remarking that many of them arose from the cervix and spread into the mesometrium; others grew from the uterus and pushed their way between the layers of the mesometrium. There is, however, a distinct variety, to which this tumour belongs, which may be described as a roughly-globular, easily shelled out, yellowish-white-on-section, and distinct from the uterus, histologically, approaching rather a spindle-celled sarcoma than a myoma or fibro-myoma. He remarked on the resemblance of these tumours in size and shape to a football, pointing out that they occurred in other retro-peritoneal situations, of which he mentioned an example in a woman, æt. 70.

MYOMATOUS UTERUS, WEIGHING TWENTY-SIX POUNDS,
REMOVED FROM PATIENT, ÆT. SEVENTY-FOUR.

Mr. BLAND SUTTON also showed a huge tumour removed from a woman, æt. 74, admitted to the Middlesex Hospital with some large and hard tumours, which, though painless, were so cumbersome that she had become bedridden. The existence of the tumours was first recognised in 1871. Nothing of note could be made out vaginally, and on September 6th he made an exploratory incision. The tumours were found to be partially calcified uterine myomata, adherent only to the omentum. Their removal occupied 40 minutes. Very little blood was lost, and the patient bore the operation well. The subsequent progress of the case was uneventful, and she left the hospital convalescent on the 29th. The tumour consisted of a number of partially pedunculated and calcified myomata. He thought that this patient was probably the oldest who had ever gone through so severe an operation as hysterectomy.

The PRESIDENT supposed the author would not deny that a myoma might form originally in the broad ligament, and he suggested that the existence of well-defined muscular tissue in that situation might advantageously engage the attention of pathologists. He mentioned that the patient, æt. 22, from whom he had last year removed a tumour weighing 44 lbs., was still in excellent health.

Mr. SUTTON, in reply, agreed that true myomata were met with in the broad ligament, and also that true muscle fibres were met with in that situation. He had satisfied himself as to this in a case of large parovarian cyst.

THE PATHOLOGY AND SYMPTOMS OF HYDATIDIFORM
DEGENERATION OF THE CHORION.

Dr. HERBERT WILLIAMSON first described the development of the chorionic villi, and the changes which occur in them when undergoing myxomatous degeneration, the changes as observed by himself agreeing almost entirely

with those previously described by other observers. The "myxoma fibrosum" of Virchow was described, and the author gave his reasons for regarding this condition as one closely allied with hydatidiform mole. He discussed the question of the priority of the degeneration of the chorion or the death of the embryo and arrived at the conclusion that degeneration of the chorion usually precedes the death of the embryo. He then discussed relation of hydatid moles and deciduoma malignum; he gave reasons for doubting the doctrine of Spiegelberg with regard to the fetal origin of the hydatidiform disease, and quoted cases of repeated hydatidiform molar pregnancies occurring in the same woman. He then dealt with this abnormality from various points of view (1) the frequency of the occurrence of the condition, and (2) the effects of (a) age, (b) multiparity, (c) rapid child-bearing upon its production; concluding that (1) Its approximate frequency may be once in 2,400 pregnancies. (2) That hydatidiform pregnancy may occur at any time during the child-bearing period, the age of the woman having very little influence. (3) That the condition is more frequent in those who have borne few children than in those who have borne many. (4) That it is not the rule for previous pregnancies to have followed upon one another with great rapidity. The results of an inquiry which he had made into the presence or absence of the usual signs and symptoms of normal pregnancy under the following heads:—(1) Amenorrhœa; (2) Vomiting; (3) Activity of breasts; (4) Blue colouration of vaginal mucous membrane; (5) Softening of cervix; (6) Uterine tumour; (7) Uterine tumour and fetal heart-sounds, led him to the conclusion that all these symptoms and signs are usually present excepting the uterine souffle and fetal heart-sounds, but sometimes even these have been heard; whilst, on the other hand, the only sign which is constantly present is enlargement of the uterus. The distinguishing features of the condition were then described under the following heads:—(1) The size and other physical characters of the uterus. Two classes of cases are shown to exist: (1) those in which the uterus is larger than would be expected from the probable duration of the pregnancy; (2) those in which the uterus is smaller. Another feature sometimes present, and of importance, is uterine tenderness. (2) Vaginal discharges, with or without the cysts. (3) Hæmorrhage. The author then discussed the diagnosis of the conditions likely to be mistaken for hydatidiform mole being—(1) Concealed accidental hæmorrhage and placenta prævia; (2) the discharge of a pelvic hydatid through the vagina; (3) hydramnion, especially if combined with hydrorrhœa gravidarum. Among complications met with he mentioned—(1) Albuminuria, a frequent complication. Two forms are to be distinguished: (a) One form in which the prognosis is good, in which blood and epithelial casts are not present in the urine. (b) One form in which the prognosis is bad, and in which these structures are found in the urine. (2) Hæmorrhage, seldom fatal in itself. (3) Sepsis; sapræmia, septicæmia, and pyæmia all being frequent complications. *Prognosis*.—The mortality of the whole 25 cases was 20 per cent. The mortality of the ten consecutive cases from St. Bartholomew's Hospital was 30 per cent.

Dr. G. HERMAN expressed surprise at the relatively high mortality given by the author, especially as nearly all the cases he had met with had recovered without its having been necessary to do more than give ergot and introduce a tent. He commented on the large proportion of deaths from sepsis, which he thought might have been prevented.

Dr. GRIFFITH thought that the high septic mortality might possibly be explained by many of the cases dating back to pre-antiseptic days. He thought that myxoma fibrosa was much commoner than was generally believed, and was often overlooked or mistaken for an ordinary carneous mole, of which two instances had accidentally come under his observation. Moderate degrees of degeneration, cystic of fibrous, or the chorion, were, he thought, by no means rare in otherwise healthy fetus. If, as suggested by the author, myxoma fibrosa was closely associated with cystic mole he thought it must be difficult

to explain how it was that in the former the chorion stumps were affected, while in cystic mole there were merely isolated patches of bullous degeneration of the chorionic tissue, with comparatively healthy chorionic stumps between. If it were regarded as a maternal disease, how did the author explain the existence of twins, one with a healthy placenta, while the other placenta presented cystic degeneration? He recalled the suggestion that this might be due to the fact of one fœtus having been implanted on a degenerating spot of the uterine mucosa. Personally he held to the view that it was a disease of the ovum. He asked whether anyone could boast of having diagnosed a hydatidiform mole apart from the expulsion of a vesicle. He had often diagnosed it, but it had always turned out to be something else.

Dr. JOHN PHILLIPS alluded to the difficulty of the differential diagnosis between this condition and concealed accidental hæmorrhage. He mentioned that he happened to have had a case of each kind on the same day, and in respect of the mole even on passing the finger into the cervix he obtained no indication of its nature. The vesicles were very soft to the touch and not unlike clotted blood. With regard to death from sepsis he himself had hardly seen even a rise of temperature.

Dr. HUBERT ROBERTS suggested that it might be that it was in such cases with this tendency to degeneration that one met with the condition described as deciduoma malignum.

Dr. MACLEAN related a case of a woman, æt. 35, who had previously borne two children, who came under observation after four months' amenorrhœa with a tumour reaching above the umbilicus. There had been slight loss of blood every two or three days, and while under observation there was a sudden attack of profuse hæmorrhage, and then for the first time some vesicles escaped. The uterus was rapidly cleared of its contents, but in spite of saline injections she succumbed. He mentioned this as an instance of death from hæmorrhage in a woman otherwise strong and healthy.

Dr. BLACKER mentioned the case of a woman who was admitted with a tumour of the anterior wall of the vagina resembling a hæmatoma which gave her much pain. It was incised and was reported to be a fibro-angioma of uncertain nature. The woman was apparently pregnant, and a few days later passed a hydatidiform mole. He did not suppose that there was any relation between the two things. He referred to the curious case recently published by a surgeon of a girl who had suffered from membranous dysmenorrhœa, who subsequently passed a hydatidiform mole, although it was regarded as absolutely certain that there had been no possibility of pregnancy.

Dr. SPENCER pointed out that the statistics collected by he author gave no clue to the relative frequency of such cases. He observed that if one could obtain *ballotement* that sign would argue greatly in favour of its being a case of accidental concealed hæmorrhage or placenta prævia. He commented on the rarity of vesicles escaping in the discharge. He only remembered one instance of death from sepsis, and in that case infection had taken place prior to admission.

Dr. LUDWIG FRANKEL, of Breslau, speaking in German on the subject of deciduoma malignum, said that Veit was alone in Germany in supporting the English view that this condition was due to sarcoma, existing independently of, and probably before, pregnancy. The general view in Germany was that it was a foetal neoplasm arising from the chorionic villi and of the nature of an epithelioma, and it appeared structurally analogous to the cases of hydatidiform mole, which by analogy were termed epithelioma benignum.

Dr. WILLIAMSON replied, and mentioned a case which had since come under his observation, which was diagnosed as concealed accidental hæmorrhage even after the cervix had been dilated. He thought the change was rather of the nature of a degeneration. He was unable to accept the suggestion that a hydatidiform mole could be present without impregnation.

PARIS, October 8th, 1899.

THE DURATION OF APPARENT DEATH.

At the Académie de Médecine, M. Laborde related fourteen new cases of resuscitation of individuals in a state of apparent death, thanks to rhythmical traction on the tongue. Of these cases, the half was relative to drowned persons who were brought back to life after a time varying from twenty to sixty minutes of traction. Up to the present, it was impossible to determine exactly the time during which the functional properties could persist in animals apparently dead. However, among the fourteen cases referred to by the speaker, there was one, that of a drowned man, who was called back to life after three hours of rhythmical traction of the tongue. The vital properties would seem then to persist in a latent state during a lapse of time which might be estimated at three hours as the extreme limit.

Another fact which deserved recognition was that with old methods of recalling to life the respiratory movements were never established where the asphyxia had exceeded five or six minutes. By means of the method of M. Laborde, on the contrary, subjects who had sojourned under water thirty or forty minutes had been very frequently reanimated.

M. Colin asked if the examination of the blood and of the heart had been practised on animals experimentally placed in a state of apparent death.

M. Laborde answered that it was found that the blood of such animals was very rich in carbonic acid, and contained only traces of oxygen, but remarked that it was never coagulated, and that it always maintained a certain temperature.

As to the heart, it was apparently stopped, and presented only slight tremulations. As soon as the respiratory movements became re-established, it began to beat strongly. It was probable that the phenomena occurred in drowned and asphyxiated persons.

VARICOSE ULCER OF THE LEG.

For the treatment of indolent varicose ulcer of the leg, Dr. Brunner highly recommends the application of a two-and-a-half per cent. of carbonate of soda. Under its influence the ulcer heals rapidly, but the same agent is not superior to other means of treatment in recent ulcers, or those covered with exuberant fungosities. His *modus operandi* is: After having washed the ulcer with a warm solution of sublimate, he applies a piece of antiseptic gauze, thinly coated with vaseline, and over this hydrophilic cotton soaked with the solution of carbonate of soda, and finally a bandage. The dressing is renewed each day. Twenty-four hours after the first application the ulcer assumes a more healthy aspect, and at the end of a few days it granulates abundantly; the callous edges become softer, and from that time the ulcer cicatrises rapidly. The definite cure is obtained in from ten to thirty days.

Certain persons cannot support the vaseline, which provokes eczematous eruptions; in such cases he replaces the vaseline by lanoline, or he applies simply and directly on the ulcer compresses wet with the solution of soda.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, October 6th, 1899.

At the seventy-first meeting of the Society of German Scientists and Physicians, after an address by Nansen, Professor v. Bergmann addressed the meeting on

THE ACHIEVEMENTS OF RADIOGRAPHY IN THE TREATMENT OF SURGICAL DISEASES.

No seer's glance had penetrated boards and beams like this dark light, no somnambulist with his clear vision had discovered such secrets. Exaggerated hopes had been placed on the curative power of the rays, and all possible diseases had been submitted to their action. But people soon became conscious that no wonder cures would be wrought by it; it was not true that other ways of curing had been discovered, but that knowledge had been increased. It was not simply the waves of the dark light, but the waves from the electrical discharges, heat waves, and a number of waves possessing chemical powers. As a matter of fact, the whole action of the waves was limited to reddening and superficial inflammation of the skin, and this effect was produced much in the same way as by a mustard plaster. The time of expectation of mysterious powers was passed. Medicine awaited from it only a furtherance of the knowledge concerning localised changes in the body. What it had done in this direction was enough to prevent its exclusion from the service of medicine. To anatomy, without an accurate knowledge of which therapeutics were useless, it rendered useful service. For the diagnosis of diseases of the internal organs it was comparatively valueless. From the fleeting images afforded by the light on the screen, for instance, it was not possible to determine commencing tuberculosis. Percussion was a more certain guide as to cardiac area and pleuritic effusion than the light, and never had any decided conclusion been reached by it as to the position of gall-stones or vesical calculi.

The importance of the new discovery was greater for surgery. The rays had done the most service in the discovery of foreign bodies and in fractures of bones. The discovery of foreign bodies and the tracking of the path they had taken in the system, and the treatment resulting from this knowledge were the greatest achievements for which medicine was indebted to the rays; they not only facilitated the removal of foreign bodies, but they allowed of others being left in that would have been sought for by operation before their employment, as such foreign bodies could often be allowed to remain in without fear of doing injury. Thus projectiles often remained in the system without doing any harm. Their removal would be more dangerous, as shown in many cases of bullet and splinters healed up in the flesh, as their removal would often necessitate dangerous and deep operations. Thus the French surgeons in the *attentat* upon Labori recognised that they would do better to leave the ball alone. They made it possible for the distinguished advocate to plead again a few days after being wounded. There were cases in which bullets were in the lungs, in the thorax, near to the heart, and even reaching this; the persons implicated bore these foreign bodies without being conscious of their presence.

The representations of the bony system had been enriched by the Röntgen rays. By a large number of Röntgen pictures, the speaker showed normal and morbid developments of the bones, particularly of the long bones, and more especially those of the hand. From other pictures not only could the age of children be recognised, but also the diseases that influenced growth. Rachitic children could now, by means of the rays, be much more successfully treated, as the Röntgen image showed accurately the favourable point of time for operation, which before could only be made out with great trouble, and not with certainty. It could now be accurately determined from what basic diseases dwarfs were developed, and French physicians had already successfully employed thyroid preparations where by Röntgen examination they had recognised the morbid foundation for dwarf growth. The observations made by the radiograph on the so-called Lilliputian troupe were interesting. Through illumination had shown that their bones, apart from their smallness, were quite regularly formed, that they were furnished with well-developed epiphyses. In fact, the people were still growing. One of them, between his 26th and 36th year had grown 20 cm., and this at a time when, in the ordinary individual, growth had entirely ceased. If this went on, and the Röntgen image showed a prospect of it, in his old age he would have to leave the troupe through becoming too tall.

The rays were also useful for the discovery of anomalies, such as absent joints or superfluous parts. The occurrence of superfluous fingers was known to the Prophet Samuel, as he mentioned a man of God who had six fingers and six toes. At that time these deformities were reckoned a sign of uncommon strength. Not less interesting were the cases of hands with the middle finger consisting of four, or, as in the thumb, two joints. Nowadays Röntgen illumination was sufficient to determine the actual condition. This might under certain circumstances have a surprisingly disagreeable effect on the individual concerned, as the following very recent case showed. A workman had been injured by a machine. He complained of pains in the lower part of the leg near the ankle. A bone was really felt there that was not present in the normal skeleton. This bone was supposed to have been split off by the accident, and then healed in. As the man was supposed to be unfit for work, he received considerable compensation. Then came in the—in this case—bad rays. These showed the like abnormality on the other leg also. It was, therefore, proof that the peculiar condition could not have been caused by an injury. The incorrectness of the professional opinion was brought to light by the treacherous rays, and the man lost his compensation.

PROTARGOL AS A PROPHYLACTIC—CREDE'S INSTILLATION.

Hr. Fritz Engelmann has for some time been using protargol in the place of silver nitrate as a prophylactic in the case of new born infants. In the University Frauenklinik, at Bonn, he used it in 100 consecutive labours without making any selections. The solution was of a 20 per cent. strength. In almost 30 per cent. of the cases there was no secretion, in about 50 a slight one, only lasting a day. In 20 per cent. the secretion became more profuse, but it lasted four days in four cases only. The opinion of the writer is that the prophylactic

instillation of a 20 per cent. solution of protargol, which scarcely irritates at all, is to be preferred to the 2 per cent. solution of silver nitrate, which is a powerful irritant. In opposition to Pargens, he shows that the stains caused by the protargol can be removed.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, October 7th, 1899.

OPERATIVE TREATMENT FOR CANCER OF THE STOMACH.

PROF. MAYDL has published the results of twenty-five operations which he has performed for cancer of the stomach. Since the days of Prof. Billroth these operations have been subjected to severe criticism, condemnation and praise alternating. Prof. Maydl divides the twenty-five cases into three classes for the sake of comparison. The first comprises cases in which the patient died from the effects of the operation either directly or indirectly. These were four in number. The second group includes those dismissed from hospital as cured but in which within a short period thereafter a recurrence of the disease took place, and death ensued. These were seven in number. The third group, which is the most important, comprising fourteen cases, included those cases in which the patients still live. This section he divides into two sub-sections, (a) living upwards of two years since operation; (b) those alive less than two years after the operation.

Of the first group four died, one from a sudden attack of gangrene in the right lower extremity, probably embolic from the tying of a vein, but this could not be confirmed, being a private patient and the friends declining to consent to a post-mortem examination. The other three died in two, three, and five days respectively after the operation from peritoneal symptoms, collapse with anæmia and exhaustion.

The second class left hospital in good health, and apparently cured, but ere long took ill with a recurrence somewhere else and died. One of the seven may be looked upon as doubtful. This patient lived fourteen months after the operation and died of pleurisy with effusion, every other organ being found healthy at the post-mortem. Even the appetite was unimpaired up to the very end, and no disease could be discovered in or near the stomach.

The other six cases lived 12 months, 8 months, 2 months, 20 months, 14 months, and 12 months respectively after the operation, or an average of 11·3 months.

Of the third class fourteen are still alive. These were operated on:—

August 27th, 1890.	January 30th, 1898.
June 7th, 1893.	October 29th, 1898.
January 27th, 1895.	October 31st, 1898.
March 1st, 1896.	November 3rd, 1898.
March 20th, 1896.	December 21st, 1898.
February 20th, 1897.	January 4th, 1899.
March 27th, 1897.	March 25th, 1899.

If these be further sub-divided into two groups of over two years and under we get the patient who may be considered cured in the surgical sense of the term. Seven may be classed thus:—

8 years	...	8½ months	3 years	...	1½ months.
5 "	...	11 "	2 "	...	2½ "
4 "	...	3½ "	2 "	...	1½ "
3 "	...	2 "			

In considering the percentages of the different authors,

the above figures give 16 per cent. as the proportion of those who die from the operation; in 28 per cent. the disease recurs; while 56 per cent. still live. It may still be remembered that C. Ewald, of Berlin, condemned this operation on account of the mortality, he having had 73·3 per cent., which was certainly not encouraging; but these results far exceeded those obtained by the pioneer of the operation, Billroth, who had a mortality of only 45 per cent. Billroth's pupil, Mikulicz, reduced this mortality to 32 per cent., while other operators, Kronlein, for example, had only 25 per cent., Carl and Fantino, 21·5 per cent., and now Maydl's mortality stands at 16 per cent.

NATURFORSCHER VERSAMMLUNG.

This year the German Science Association met on the Isar, at Munich, which was well attended by representatives from every Continental city, but more especially from the German-speaking race. As advertised, Frithjof Nansen, the North Pole explorer, gave the first plenary lecture, which was mainly geographical. He illustrated his remarks by a large diagram of the plumbing of the North Polar sea, which reached 4,000 metres (13,000 feet). The temperature of the water at the depth of 200 metres was exactly at zero Centigrade; at a depth of 800 metres it was -1 deg. Centigrade. The solid matter (or salt) in the water at the surface was so small that it could be used for drinking purposes, but when a depth of 250 metres was reached the salt in the water was normal. The lowest reading of the atmospheric temperature was 53 degs. Centigrade, or 62 degs. Fahr. The summer temperature averaged 0 degs. Centigrade.

There were thirty-seven sections, but that dealing with wireless telegraphy was by far the most popular.

TUBERCLE BACILLUS CULTIVATION.

One of the distinguishing features of the tubercle bacillus is its slow growth, but according to St. Hesse this is purely on account of the nature of nutrient media employed. With Hayden's media in an incubator he can obtain from a contact inoculation a culture in five to six hours. In the sputum, which is rather more difficult, he can determine in from half a day to one day. The media, as prepared by Hayden, contains common salt 5 grammes, glycerine 30 grammes, agar agar 10 grammes, solution of soda (28·6 in 100) 5 cc, distilled water 1,000 grammes. In experiments on animals this is of great advantage.

DEATH OF PROF. PUSCHMANN.

Another of the professorial staff has passed away at the comparatively early age of 45, after chronic nephritis of long standing.

Born in Prussia, he was educated at Berlin, Marburg, Munich, and Vienna. After qualifying, he went to Tunis and Egypt, and settled in Cairo for two years as a general practitioner. In 1878 he returned to Leipzig, where he acted as Docent in Historical Medicine. He was soon after this appointed Assistant Professor of Historical Medicine in Vienna, and finally Professor, which post he has filled with dignity since 1888.

His twenty years' residency in Vienna has endeared him to the University as one of its most ardent supporters, and one who will be greatly missed.

South Africa.

[FROM OUR OWN CORRESPONDENT.]

CAPE TOWN, Sept. 20th, 1899.

THE WAR SCARE AND ITS EFFECTS.

MEDICAL matters are extremely quiescent, the perpetual war tension absorbing every one's attention. It is detrimental to all work to a degree which English people can hardly realise. One effect is the exodus of many of the best known local practitioners from Johannesburg. Mr. Kendal Franks has been here for some weeks. Having spoken at the great meeting which followed the Petition, he was manifestly suspect, and receiving information that a warrant for his arrest had been signed, he got away only with difficulty. Dr. Harding and several others are also here. Dr. Davies and some *confreres* in Natal. These gentlemen state that it was not only the immediate prospect of arrest that led them to leave, but the constant danger of assassination, to which, of course, the necessary nocturnal nature of a medical avocation exposed them particularly. Numbers of the Boers openly threaten to kill objectionable Uitlanders, and the police cannot be relied upon for protection. Dr. Matthews, a very prominent Uitlander, formerly a member of the Cape Parliament, is, however, holding his ground most pluckily, and lately gave evidence against a policeman who had grievously maltreated an American coloured man. At the moment of writing war is regarded as certain, and the Transvaal Government is making medical preparations in a way. It has, of course, no properly organised medical military service, but the St. John's Ambulance centres in Pretoria and Johannesburg are organising corps and being subsidised largely by the Government, so that, practically, the Red Cross will be a branch of the burgher forces. The Johannesburg centre has just applied to Cape Town for more material, and we have sent all we can spare. On the British side nothing has been done outside the R.A.M.C., but several medical men have offered to join that corps as civil surgeons if required, and the Cape Town St. John's centre has offered to supplement the military resources by fifty bearers and corresponding equipment. It has already cabled to England for more supplies.

The "Anthony" case, of which I gave you some particulars before, has been investigated by a committee of the local branch of the B.M.A., the result being a report which, practically, found him guilty of "covering" the man Tate, and commented severely on looseness shown in granting death certificates. The editor of the *South Africa Medical Journal* also came in for censure. He had given evidence in the case, and had recorded his opinion that it was quite permissible to fill in death certificates on the mere statements of friends of the deceased, without any clear knowledge or record of having attended the patient. This position, taken up by a representative man, was roundly condemned by the Committee. The report was adopted at a large meeting, with only two dissentients, one being the editor of the *South Africa Medical Journal*. Dr. Anthony has not resigned in consequence, nor is he in the least likely to do so. Whether any action will be taken to bring pressure upon him is not clear.

THE NEW PHARMACY BILL AND THE MIDWIVES.

Our Medical and Pharmacy Bill, which promised well,

has been grievously emasculated by the Dutch members of the Houses, especially in the Legislative Council, where a whole tirade of charges against the profession as a whole was fired off. Your average Dutch legislator hates a doctor or a veterinary surgeon cordially. The clause forbidding chemists to practice was dropped in the Assembly. Practically all we have got is an additional member of the Medical Council, and a little strengthening of the poisons enactment, with an extension of the penal clause *re* puerperal fever to unlicensed midwives. Under the old Act a medical man or registered midwife could be baled before a court for failing to take proper precautions, an unlicensed woman went scot free. But even this clause had much ado in getting through. Only the intervention of the President of the Council, who, of course, very rarely speaks, forced it through the Dutch members. As an instance of the inconsequential way in which the Boer argues, one sapient legislator gave, as an argument against the midwives' clause, an instance of a Cape Town medical man having charged a patient £65, then accepted £20. What this had to do with the necessity of unlicensed midwives keeping themselves clean, goodness only can say. In justice, one must admit that the profession is worked on terribly commercial lines in this country, and the field is so overcrowded that things are becoming worse in this respect every day.

Lunacy Department.

SCOTCH LUNACY BLUE BOOK.

THE Scotch Commissioners make their Annual Report more interesting than that of the English Commissioners, because the Blue Book contains, not merely a collection of statistical tables, but an elaborate financial statement, comparative in its character and enabling one to see at a glance the relative economic position of different Scotch Asylums. In addition to this, the Scotch Commissioners' Report is interesting, because of the important questions which are introduced and discussed in it, and it certainly does more on that account to bring itself in touch with the asylums administered by its Commissioners, and to enable superintendents to follow indications, and so organise and develop these institutions. In the report just issued many important questions are introduced, and the first of these is, "Changes among attendants and servants." They recommend that the administrators of asylums in which changes among attendants occur frequently should inquire carefully into the causes, and should endeavour to remove them by offering increased inducements to good attendants to remain, and to a better class to take service. Their experience tends to show that, in the case of men, a high class of attendant, and security for permanent service, are best obtained by increasing the number of married attendants. There are, however, many questions which are not settled by offering houses to married men, and there are many assigned causes often unreliable, and reasons which are difficult to reach and understand. The Commissioners have laid a comforting unction to their souls in that the Register, which they keep, of attendants and servants dismissed for mis-conduct, is a safeguard against these being taken on again in other asylums; but it is doubtful if this system does much good, for

the simple reason that it is not sufficiently thorough. There are many who resign in order to anticipate dismissal, and those are perhaps even worse characters than those who receive notice. A more elaborate register is required, and the Commissioners might assist superintendents considerably by the introduction of such a register, and by insisting on fuller reports of attendants and servants who resign, as well as those who are dismissed. The reports of the Deputy Commissioners embodied in the general report are as usual interesting, and contain much useful information regarding the management of the chronic insane in private dwellings. Dr. Sutherland is very confident that real abuses scarcely occur without coming to light, owing to the fact that patients are visited seven times a year. We question, however, if this system of visitation is as frequent as it ought to be. Undoubtedly, boarding out patients in private dwellings is a good idea, and the principle is a good one in theory, and often in practice, but it has not been so popular with inspectors of poor and parish councils as it ought to have been, and the visits made to patients boarded out are not sufficiently frequent. It is interesting and satisfactory to know that Dr. Sutherland has had no complaint of cruelty, neglect, harsh, or unfeeling treatment or of overtaxing the strength of willing workers. Dr. Charles Macpherson reports that the insane poor in private dwellings are being well provided for, and that the arrangements for their care are fully keeping pace with the general improvement in home comforts which is observable throughout Scotland among the poorer classes. Guardians are year by year more thoroughly realising what the requirements of the Board are—what standard of comfort must be reached—if they hope to retain the patients in their care. He observes, "The ideal in boarding-out is to place the patients as nearly as possible in the same position as they would probably have occupied if they were not insane—to board them with people who are willing to regard them as their social equals, and to share with them a common sitting-room and a common table."

The Commissioners have of late had their attention strongly directed to the advantages derived by a large section of the insane from their being placed under the constant care and supervision of nurses during the night. They are strongly of opinion that the single room idea in the construction of asylums must be modified in the future. They must occupy a subordinate place in asylums instead of being, as has at one time been the case, the leading feature. The better the arrangements for night nursing, the less necessity there is for the use of single rooms, and many patients are now kept under observation in dormitories, who previously would be placed in side rooms. The Commissioners have issued a return to Superintendents of Asylums in order to ascertain what their arrangements as regards night nursing are, and we hope to find, as we likely will, the result of this inquiry in their next report. Endeavours are being made to obtain a more accurate statement as regards the prevalence of phthisis in asylums. This is a step in the right direction. Some interesting information is given as regards the cost per patient in district asylums, of land, building, &c. The cost of our asylums is a matter of very serious concern to the ratepayer, and it is questionable whether there

is not too much extravagance in the construction and furnishing of these buildings. The General Board of Lunacy should be in a position to put a veto on unnecessary expense, for it is a public scandal that the ratepayers are taxed so much, and without redress, at the mercy of asylum authorities. When we think of asylums costing £400 a bed or more, and think that that sum would build a commodious cottage for a working man and his family, it seems nothing short of scandalous. The tendency is more and more to elaboration, while a refining system of management and the competition of one asylum with another for pre-eminence is such that money requires to be spent to keep it up. The whole tendency of local government is always towards increased expense, and if we could see any adequate results there would be nothing to say, but the adequate results are sadly wanting. The statistics of maintenance expense are very interesting and raise many questions. In asylum finance one must be careful not to draw too arbitrary conclusions, and suppose that because the cost of food in one asylum is £2 a year more than another, that the one with the highest cost feeds its patients best. We have to consider the fact that one asylum may be further from a good market than another, or it may have a demand on it of a different kind. All the food does not go to the patients. More or less is wasted and goes to the pigs, there may be extravagance in the official consumption, or the local board may make undue demands on the asylum cupboard.

Much more might be said regarding this report, but we must leave its perusal in whole to its readers, as space forbids our taking further notice of it. It is, however, a more interesting, practical, and suitable report than many of our Blue Books.

The Operating Theatres.

ST. PETER'S HOSPITAL FOR STONE.

LITHOLAPAXY FOLLOWED BY SUPRA-PUBIC LITHOTOMY FOR ENCYSTED CALCULUS.—Mr. SWINFORD EDWARDS operated on a man, æt. 65, who had suffered from symptoms of stone in the bladder for the last two or three years. On sounding the patient a stone was easily discovered. For purposes of demonstration cystoscopy was undertaken, when a large white mass was seen projecting from the bladder floor; so white and sharp were some of the crystals that it reminded one of a range of snow-capped Alps. This was seen and verified by many medical men present. Behind this white mass was a dark-looking substance, which appeared to be a deeper portion of the stone. A week subsequent to the cystoscopy the patient was placed on the table for operation and a good sized lithotrite was introduced. About 1 oz. of debris having been removed, which presented the appearance of ordinary washing soda, Mr. Edwards sounded the bladder to make sure all had been taken away. The sound came into contact with a large piece of stone, which felt fixed, nor could this be dislodged. A finger in the rectum showed at once that this was a stone occupying a site between the bladder and the rectum on the patient's right side, and it was a question as to whether this was a stone impacted in the vesical orifice of the ureter or not. Supra-pubic cystotomy having been performed in the usual method, the finger

was passed into the bladder, and there discovered the remains of the stone projecting into the viscus from a pouch with a small neck; it was with considerable difficulty that the operator enlarged this neck with his finger sufficiently to permit extraction of the stone, which was ultimately done with lithotomy forceps. The stone was of a dark colour, which contrasted in no small degree with the white intra-vesicular portion. Mr. Edwards pointed out that had he recognised that this had been a pouched stone he would have proceeded to do supra-pubic lithotomy at once instead of attempting to remove it by litholapaxy. There are some surgeons, he said, who advise even in cases of pouched stone that an endeavour should be made to grasp it with the blades of the lithotrite *in situ*, and by this means remove it into the general cavity of the bladder, and there crush it. Mr. Edwards disagreed with this procedure, believing that it was fraught with considerable risk to the patient; indeed, he quoted a fatal case in his own practice where the patient died of acute peritonitis after an operation of this kind, owing to damage done to the cystic wall in crushing. Mr. Edwards, therefore, strongly advocated lithotomy in all cases of true encysted calculi. It was probable that the stone in this case was encysted in the vesical end of the right ureter though this was not proved. He said that the diagnosis of encysted stone is not always an easy one for large stones, either lying in a post-prostatic pouch or in the *bas fond* of a contracted bladder permit of very little movement by means of the sound, but in stones of a more moderate size the sense which is imparted by the sound to the hand will often enable an experienced surgeon to form a correct opinion as to whether the stone is encysted or not. He pointed out that if during many examinations the calculus is always found in one definite spot it would cause one to suspect a fixed stone. In the case under notice had he examined *per rectum* carefully before operating he would doubtless have discovered that owing to its clearly defined outline part of the stone lay outside the true bladder wall.

It is interesting to record the fact that the patient has made an uninterruptedly good recovery; it is now a month after the operation, and the man is getting about the ward, and the pubic wound is healed; there is some atony of the bladder, for which catheterism is necessary.

Vital Statistics.

THE deaths registered last week in thirty-six great towns of England and Wales corresponded to an annual rate of 19.1 per 1,000 of their aggregate population, which is estimated at 12,786,832 persons in the middle of this year:—

Birkenhead 18, Birmingham 23, Blackburn 14, Bolton 22, Bradford 12, Brighton 17, Bristol 14, Burnley 17, Cardiff 16, Croydon 14, Derby 16, Dublin 33, Edinburgh 18, Glasgow 18, Gateshead 22, Halifax 14, Huddersfield 17, Hull 25, Leeds 20, Leicester 18, Liverpool 26, London 16, Manchester 25, Newcastle-on-Tyne 23, Norwich 13, Nottingham 21, Oldham 21, Plymouth 15, Portsmouth 17, Preston 27, Salford 26, Sheffield 24, Sunderland 24, Swansea 16, West Ham 16, Wolverhampton 20. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From whooping-cough 1.2 in Leicester, and 1.6 in Portsmouth; from fever, 1.4 in Sheffield, and 2.3 in Birkenhead; and from diarrhoea, 3.1 in Liverpool, 3.3 in Nottingham, 3.6 in Salford, 3.7 in Birmingham, and 5.3 in Preston.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, OCTOBER 11, 1899.

RECALCITRANT BOARDS OF GUARDIANS.

THE position in which the Leicester Board of Guardians now find themselves is strongly suggestive of the unhappy state into which the obstinacy of the Boers has precipitated the South African Republic. So far as the Leicester Guardians are concerned their refusal to appoint a vaccination officer in accordance with the Vaccination Act of last year has been treated from the first with leniency, nevertheless firmly, by the Local Government Board. Moreover, much official diplomacy was exercised in order to bring about a peaceful solution to the difficulty. But the Guardians evidently interpreted this action of the Board as indicative of a disinclination to proceed to severe measures, and consequently the obstinacy of their refusal was maintained. However, last week an ultimatum was sent to the Guardians calling upon them, by means of a peremptory mandamus of the High Court, to appoint a vaccination officer. These recalcitrant officials—forty-five in number—have the matter under their consideration, and should they determine to ignore the order of the High Court, for this misdeed they will have to adjourn to gaol, where abundant opportunity will no doubt be afforded them of further pondering upon the folly of the course which they have adopted. But they will have something more to think about should they bring upon themselves this penalty. If they decide to go to gaol rather than yield they will have the grim satisfaction of knowing that, while in durance vile, the Local Government Board will undertake the duty of appointing a vaccination officer for the Borough of Leicester, and a correspondent in a local paper has pointed out that the last state of the anti-vaccination party in the town will thus have a good

chance of becoming worse than the first, inasmuch as the officer whom the central authority are likely to appoint would be certain to be one chosen from the ranks of "the enemy." Thus it is plain that some of the anti-vaccination party are by no means satisfied with the attitude assumed by their local guardians. The feeling is, in truth, beginning to prevail that a huge blunder is being committed, and that before worse happens the Guardians should withdraw their opposition. The blunder, if carried through, is described as one that would be irretrievable, and altogether the situation is being regarded by many with a good deal of concern. In reflecting upon all the points of the case it is impossible to deny that the Board of Guardians, by their foolish obstinacy, have played into the hands of the Local Government Board in the same way as the Boers, by the same means, have played into the hands of the Imperial Government. The Leicester Guardians, up to the present, have foolishly determined to defy the law—a very weak method for a public body to adopt under the circumstances of the case, and one which can scarcely be commended as setting a good example to the townspeople, by whom they have been placed in their position of responsibility. Furthermore, on tactical grounds the Guardians do not stand to do themselves any good, inasmuch as practically it is useless for them to fight an authority like the Local Government Board, who besides have the law on their side. We agree, then, with the anti-vaccination protestants in Leicester that the Board of Guardians are acting very unwisely in the interests of the local anti-vaccination party. It is quite conceivable that the individual members of the Board are not particularly desirous of posing as martyrs in the gaol of their town, and, perhaps, it may be that by now a good many of them are reluctant to undergo this extreme penalty for their obstinacy. However, a graceful opportunity has been afforded them by their party of withdrawing from the position which they have assumed, and if they are wise they will avail themselves of it. But it is no part of our duty to point out what the Guardians should do under the circumstances; nevertheless, in no case can they retrieve their position of being sensible persons. In making a miserable effort to defy the law they have simply afforded another proof of the childish folly so commonly displayed by members of the anti-vaccination party. Perhaps when the next election for this Board takes place, the townspeople of Leicester will see the necessity of returning persons at the head of the poll prepared to do their duty rather than to set a bad example of refusing to obey the law of the land.

A LAY "CURE" FOR LEAD POISONING.

THE hunger for specific cures is one of the most characteristic mental features of the average citizen of the United Kingdom. It is this amiable failing that cozens him into supporting the vast industrial organisation which supplies him with medicines

warranted to cure any or all of his bodily ills, from toothache to advanced Bright's disease or locomotor ataxy. Philosophers tell us that the typical Britisher feels bound to have an opinion upon every subject, as, for instance, whether a distant star is, or is not, inhabited by highly organised animal beings, equivalent to mankind on our own terrestrial globe. It is this sturdy self-assertiveness of individual belief, doubtless, that leads to a kind of national assumption of capability to judge correctly of medical matters, however complicated and technical. Indeed there is reason to doubt whether any great reform of preventive medicine could ever be carried out successfully without the full assent and approval of the general public. The crusade against consumption has been skilfully conducted so as to take the laymen into the confidence, as it were, of those medical men who have educated the community at large through the medium of the public press and of public meetings. Indeed, this whole movement savours of the precise business handling that the medical profession bewails the lack of in theory, but loses no opportunity of exercising in practice. However, the immediate object of the present article is not to discuss the vexed question of what particular code of ethics should regulate the conduct of the men of light and leading in medicine, but to discuss a new so-called "cure" that has lately been sprung upon an astonished world of newspaper readers. All our readers are, of course, familiar with the effects of lead, both in its acute and its chronic phases, upon the human system. In many respects the subject of plumbism is one of the most fascinating in the long list of maladies that are brought under the notice of the physician. The blue line on the gums, the profound anæmia, the colic, the constipation, the gout, the organic changes, the epilepsy, the palsies, and various nervous phenomena, together form a vivid and peculiar picture. In its chronic form plumbism is an intractable and well-nigh hopeless condition, although, of course, many of its symptoms, such as anæmia, constipation, and palsy are capable of great relief under appropriate medical treatment. Now it has been announced with a flourish of trumpets that many cases of lead poisoning have been absolutely cured by electric baths at Wolverhampton. That any system of electro-therapeutics devised is able to cure chronic lead poisoning we altogether doubt. That some forms of electricity are of great value in treating the paralysis of groups of muscles which is one of the many peculiarities that stamp this strongly individualised condition, is known to every tyro of medicine. It looks very much as if some enthusiast unversed in medical matters had noted the recovery of palsied muscles under the influence of electrical baths, and from that observation had jumped to the wide conclusion that the lead poisoning at the root of the palsy had also been cured. As to slight recent cases of lead poisoning there is little question that they might get right under a course of electric baths, just as they would under any other methodical living under rational and healthy conditions away from any

fresh exposure to the poison. Having arrived at the conclusion as to the specific potency of the baths, however, the Women's Trade Union League have sent as many patients to Wolverhampton for special treatment as their means would allow. That body is now appealing to the public for funds to enable them to extend their sphere of operations, and their appeal contains the following succinct statement: "The sum of £5 is the average amount required for sufficient treatment to restore power to a person suffering from paralysis." A less sum, it may be remarked, would be required if the patient were sent for a course of electric treatment to any well equipped public hospital. At the same time it may be freely admitted that the course recommended by the Women's League is calculated to cure the single symptom of palsy in all but the most advanced cases. What we object to is the assertion of the cure of lead poisoning by these special baths, a claim that is not only misleading but dangerous. The Women's League, if we may venture to give gratuitous advice, would do well to see that trade regulations are carried out wherever lead is used in factories. The compulsory use of leadless glaze may be regarded as a simple first step on the road towards efficient prevention. Meantime we regret that we cannot endorse the announcement of a new cure for lead poisoning, and, as a necessary corollary that we are unable to urge the claims of the subscription list for the purpose of using any special electric baths for the "cure" of that condition.

THE INTRODUCTORY ADDRESSES.

THE introductory addresses with which it is still the custom in some medical schools to inaugurate the winter session are always interesting reading to those who take an interest in their profession, although it is open to question whether the benefit to the listener is always proportionate to the pains which they must have cost to compose by those upon whom the oratorical mantle has fallen. Nominally intended for the guidance and edification of new students, these addresses usually deal with scientific or ethical problems as yet far beyond the ken of the ex-schoolboy. The inconsistency of employing antipyretic drugs to reduce a high temperature which is probably merely an indication of the intensity of the reaction of the organism to the disturbing agent is not a point in which he can as yet interest himself. Even the importance of pathology as a guide to etiology may leave him cold, while dissertations concerning overcrowding of the profession and the increasing difficulty of gaining a livelihood therein can only have the effect of discouraging his youthful ardour to acquire the right to practise. The address delivered by Sir James Crichton Browne, at Owens College, on "The Quest of the Ideal," which we publish elsewhere, represents a type of inaugural address which conforms to one's conception of what such an address ought to be the moment it ceases to be a homily to students on the importance of assiduity and the moral obligation of sobriety and chastity. His insistence on the

importance of not falling victims to the prevailing dogma of materialism and his eloquent pleading for the cultivation of the ideal come very opportunely as a reminder to those who are about to commence their studies that there is something above and beyond the mere acquisition of technical knowledge, however useful that may be in its way. Medicine has been defined as "the experimental analysis of life in health and disease," but the analysis is only tentative and does not assist us materially to unravel the fundamental mystery of life. Anatomy enables us to form some idea of the intricate mechanism whereby the principle of life finds utterance and physiology unfolds to our astonished eyes a blurred glimpse of its workings, but there is nothing "telling us where life has been, whence it issues." The realm of science is so vast and human knowledge is so limited that to restrict one's intellect to the finite is a process akin to that of refusing to look at Nature except through the objective of a microscope. A high ideal is a necessary basis on which to rest a high character, and a man who frankly and unreservedly gives himself up to gross materialism thereby deprives himself of the compass which should guide him amid the temptations and trials of this existence, and enable him to live a blameless life spent in the service of humanity. Sir James Crichton Browne's address is a lay sermon adapted to present-day requirements. The prelate who is to preach at the annual gathering of medical men at St. Paul's could choose no worthier subject than this quest of the ideal. Nothing more promptly dwarfs the intellect and undermines the character than concentrating one's mind and energy too exclusively on the material details of our daily existence. If we wish to acquire and retain the esteem of our fellowmen, if we wish to lay the foundation for a quiet conscience and to prepare for a happier hereafter, let us follow the orator's injunction and cultivate the ideal.

Notes on Current Topics.

The Question of Dress.

"HONOUR peereth in the meanest habit," and yet the Royal College of Physicians, of London, is seeking to glorify itself by dress. We can understand the Lord Mayor and others in office, and those, too, of the Royal Colleges who wear gowns, &c., when on duty, appearing in public in their robes, but to ask the graduates of various Universities, which have nothing to do with the Medical and Surgical Corporations, to don gowns which they generally have to borrow is rather absurd, and not likely to increase the respect in which the profession should be held by the public. After all, what is the object of gowns being worn by men at Universities or by the barrister when in court? It is certainly not to add to personal and individual character. What is the purpose of the footman's livery or the soldier's uniform, except that it is to show there is something more important and very different from the person which is on duty, "And thither walk on foot" is

part of the programme drawn up for one ceremony at which the robes are to appear. Whether the great anatomist in whose honour the oration was given would have wished his colleagues and friends to attend in robes is doubtful. We think he would have agreed with the great dramatists of his own time, " 'tis the mind that makes the body rich." Whether the scarlet gown or the black silk of the M.D. of our old Universities should be worn is left, we presume, to choice: and if the square cap is a part of the dress, the borrowing will not be an easy matter. When the ceremony is over, and a little time passes after the oration, we think that many will agree with Petruchio, "It is now some seven o'clock, and well may we come there by dinner time."

Women Students and the Medical Jericho.

THE Governors of Owens College have decided to admit women students to their classes, an example which will, sooner or later, we imagine, be followed by many other medical teaching institutions. In Edinburgh, if we understand aright, the School of Medicine for Women has closed its doors because female students were admitted to mixed classes, thus rendering separate classes supererogatory. Something may be said in favour of separating the sexes during the first two years of medical training, inasmuch as this can be done without any difficulty, but when it comes to clinical work the system becomes absurd, and it is only in England that such an incongruous idea has been received and acted upon. The curious hypersensitiveness which takes alarm at the presence of women students in the operating theatre, but sees nothing objectionable in the presence of nurses, is so ludicrously inconsistent that it must perforce die out with the race of men who introduced it. The walls of the medical Jericho are falling to pieces, and we are getting within measurable distance of the time when the principle that science has no sex will be generally acted upon.

Medical Certificates in Law Courts.

HIS Honour Judge Emden, of the Lambeth County Court, made the curious announcement the other day, that he would never again pay any attention to medical certificates handed to him which did not specifically state the complaint from which the patient suffered. This remark was a *propos* of a medical certificate in which the practitioner stated, "I consider the plaintiff unfit to attend the Court." His Honour held that the question of whether a person was or was not in a fit state to attend was one for the Court itself to decide. We must demur from this ruling. Why should the nature of a person's illness be made the common knowledge of the multitude? Would the judge be willing to apply this decision to his own case? Let us suppose that Judge Emden falls ill and has to send notice to his Court of his inability to attend. Would it appear right to him that on the receipt of the notice the clerk of the Court should rise and inform those present that (say) "Judge Emden is suffering

from a bad attack of piles, and is consequently unable to preside to-day?" What is sauce for the goose is sauce for the gander. A hapless litigant should not be called upon to have a public announcement made concerning the nature of his illness, merely because the judge may, rightly or wrongly, have some doubts as to the *bona fides* of the medical certificate. Surely a better way would be to accept the certificate conditionally upon further evidence being produced that the opinion therein expressed were capable of confirmation. Judge Emden could easily say, "I accept the certificate, but I shall require it to be endorsed by another medical man." He states past experience has taught him to regard some medical certificates with grave misgiving. If this be the case, the remedy which we suggest would be the right one in order to arrive at the truth.

A Proposed Crematorium for Leeds.

THE Leeds Cemeteries Committee have been discussing anew the proposal of erecting a crematorium for the town, and with that object in view they are about to pay a visit of inquiry to Manchester and Liverpool and several other places for the purpose of ascertaining how the system is practically carried on. There is no doubt that a crematorium is a most useful adjunct to a large town, and we believe that the promoters of the one at Manchester have been abundantly satisfied with the financial success of their enterprise. Moreover, there can be no question that the sentiment against cremation is gradually, but surely, dying out. The lead, of course, in this direction is being taken by the well-to-do classes, but there is no reason why, in the future, the poorer classes should not follow suit. At present, however, the cost of cremation is somewhat prohibitive, and the ceremonial of an imposing funeral has such a hold upon popular sentiment that some generations, perhaps, will be required to depose it from that position. Nevertheless, from a sanitary and hygienic point of view, there is so much in cremation to recommend it that we believe that the good sense of the people will gradually lead them to adopt this method of the disposal of the dead.

Notes on the Plague in Spain.

THE Government Gazette of last Tuesday contains a Royal Order instructing the provincial sanitary inspectors to daily examine into the efficiency with which the sanitary laws are carried out, so that the "death-bearing" plague may be shut out of the country. Don Decis Carlan (*El Siglo Medico*) states that, in all, ninety cases of plague have occurred in Oporto, and that the plague is like a drop of oil extending along its outer boundary to all the villages in the neighbourhood. It is feared by the populace that if God has not mercy on them by sending cold weather to stay its progress the whole country will be overrun by the epidemic. The Portuguese authorities, he writes, are responsible before God and man. They have neither the wisdom nor the thoughtfulness to contend with a pestilence which is

causing now such calamities as humanity deeply lamented in bygone ages. A correspondent of *El Liberal* writes: "In the evening we were in Oporto, in the shoreward of the Douro, which includes *Honte Jaurina*, the street in which the first case of the pest was found, dead rats and even dead rabbits—in the very focal point of the plague—the death threatener of Europe. Should not the quarter be burnt down and rebuilt.

The Dual Medical Officership at St. Olave's.

THE wealthy South London parish of St. Olave's, Southwark, continues to pay a salary to two Medical Officers of Health. As readers remember, the Board suspended Dr. Bond from office for failing to report to them the removal of bodies from a church, and appointed Dr. Dixon, the Medical Officer for Bermondsey, to discharge the duties of the post. The Local Government Board refused to sanction either the suspension or the appointment, and ordered Dr. Bond's reinstatement. Although some weeks have elapsed since the receipt of the departmental communication, things are still in *statu quo*. There can be no doubt that the Local Government Board will shortly intervene to stop this scandal of a two-headed sanitary officership. By the way, we note that the newcomer, Dr. Dixon, has presented a fortnightly report to the Board, which presents a rose-coloured picture of the health of St. Olave's. The death-rate was returned at 14 per 1,000 as against 18·8 for London. When we take into consideration the mortality returns for neighbouring districts in South London, it is impossible to avoid a suspicion that there is some fallacy in the correction of the figures upon which the St. Olave's rate is based. As instance of the fallacies we have in mind are the deaths of parishioners outside the parish, and those of non-parishioners dying in the parish. The presence of a large hospital like Guy's in St. Olave's introduces a large possible element of error. It is to be regretted that the death returns of the various districts are not based compulsorily on a rational common plan.

Drug Adulteration.

AT a prosecution at Market Harborough last week it transpired that a seidlitz powder purchased for analysis contained only nine grains of potassium tart., when it ought to have contained 120 grains, but it made up for the deficiency by containing 127 grains of sodium bicarb. when it ought to contain no more than forty. The usual plea was put in—i.e., that the vendor obtained the powders from a "well-known firm" of middlemen who themselves got them from a London firm "of high standing" in exactly the same condition in which they were sold. This plea reminds us of the epigrammatic charge delivered by a celebrated Judge who was trying a culprit for stealing a horse. Having heard a mass of evidence as to the excellent character and admirable qualities of the prisoner, his lordship said, "Gentlemen of the jury, after the irreproachable testimony which you have just heard, no one can entertain a doubt that the prisoner is a most respect-

able man, but neither can there be a doubt that he stole the horse, and you will, of course, find him guilty." The "high-class" and "well known" firms were, of course, supremely respectable but equally guilty.

Isolation Hospital for Dublin.

THERE is a good deal of controversy, especially in medical circles, as to the proposals of the Public Health Committee of the Corporation to build a Municipal Hospital for the accommodation of infectious cases, but the dispute resolves itself very much into one as to whether it is best for the Corporation to cater for itself or to spend the same money as a subsidy to Cork Street and other fever hospitals which have, heretofore, been attempting to do the work. Obviously, the existing accommodation for infective disease in Dublin is insufficient to meet an epidemic emergency, and it would be well if the Corporation could escape the risk of a big hospital speculation by helping the existing hospitals to make it sufficient, as to which, it may at once be stated that schemes involving an outlay of £250,000, such as were realised in Glasgow and elsewhere, are totally out of the question in impecunious Dublin. Apart from this, there is the very great objection to remitting to any combination of private bodies the control of a system which ought to reside in the municipality, and the efficiency of which would depend, in great measure, upon central administration. The medical side of the controversy may, we think, be put aside by the Corporation in dealing with the matter, because their sole duty is to ensure that each infected patient shall be safely isolated, and, in theory at all events, this cannot be done in small wards attached to general hospitals, no matter how well these may be managed. Fever, in our opinion, is a speciality which the student ought to learn in a special hospital, just as he now learns midwifery and gynaecology and ophthalmology, and it is not to any one's eventual advantage that he should be supposed to learn it over a few beds in the annexe of a general hospital. It would be easy to make room in the curriculum for such special study, by wiping out such rubbish as lectures on insanity, which are now compulsory. On the whole, we trust that the Dublin Corporation will not be deterred from forcing this question of the infective disease hospital to the front, and, by some means, providing sufficient accommodation for the fevered poor when needed.

The Royal Orthopædic Hospital.

IT will be remembered that in the course of last summer the policy of the then management of the above well-known old-established medical charity was called seriously into question. Without entering into details it may be briefly stated that the insanitary state of the building was proved beyond the shadow of a doubt, while the unwisdom of the proposed sale of the Oxford Street site was effectually demonstrated. The resignation of the President and Council was followed by prompt and decisive action on the part of the new management. The committee

have been fortunate in securing the services of Mr. Harry Marks, M.P., as their new president, and his access to office has been the signal for the display of some much-needed energy. The whole hospital has been closed for some months, and extensive sanitary and architectural improvements have been carried out under the direction of Professor Corfield, at a cost of £2,000. A special Court of Governors will be held shortly for the purpose of remodelling the rules of the institution, and it is announced that while the Committee desire to bring the rules more into line with modern hospital requirements, it is not proposed in any way to interfere with the general position either of Governors or of Committee. It is sincerely to be hoped that this charity, which has done so much good in the past, will enter upon a fresh career of usefulness to suffering humanity under the auspices of Mr. Marks and his fellow-workers.

Quarantine for Tuberculous Persons.

It is quite possible to believe that in the process of time tuberculous persons will be dealt with as infected individuals, and restraint placed upon their intercourse with the healthy members of the community. A movement in this direction is actually taking place in America. For example, in California the State Board of Health have passed a resolution to the effect that measures should be adopted prohibiting the entrance of tuberculous persons into the State. The climate of California is regarded as especially valuable for the cure of phthisical people, so much so that it is stated no fewer than 20,000 of these enter the State in a year, of whom, perhaps, about 1 in 50 recover. At the same time, it is pointed out that such a huge accession of tuberculous cases into the State can only result in disseminating the disease among many of those who otherwise would remain uninfected. A medical man in the State has also asserted that tuberculous patients should be prevented from attending churches, theatres, public or social gatherings, and that they should not be allowed to occupy public conveyances, such as railway carriages and omnibuses. All this goes to show that the more the public comes to learn regarding the infectivity of tuberculosis the worse will the position become of those who suffer from the disease. In the days of old the lot of the lepers must have been an extremely unhappy one, and the trend of opinion seems in the present day to be in the direction of limiting the intercourse of tuberculous persons to those who are similarly infected. But, however this may be, it is nevertheless certain that in the past a great deal of tuberculous disease has been disseminated by the unrestricted co-mingling of healthy with diseased persons, and there is no doubt that much good will result from letting the public plainly understand the desirability of putting a stop to this promiscuous intercourse. Prevention, after all, is undoubtedly the great thing in the case of a disease like tuberculosis: for the less persons there are who suffer from it, the less there must be by whom it can be disseminated ;

each case may become the focus of transmitting the disease to a healthy person, and if means can be taken to prevent such transmission, it is obvious that a great point has been gained.

The Recent Health Congress at Blackpool.

THE programme of the Health Congress that met recently at Blackpool was much like that of most of these meetings. The question of the prevention of tuberculosis was prominently raised, but nothing very novel was advanced as a contribution to the practical politics of the subject. This fact is somewhat to be regretted when we consider the mixed nature of the assembly brought together by the energies of the Royal Institute of Public Health. What an opportunity was afforded in these discussions for educating the minds of dilettante noblemen, mayors, vestrymen, sanitary inspectors, *et id genus omne*, who swarm around the congress chambers as bees congregate near honey pots! Not that we would infer there can be a momentary doubt as to the value of the diffusion of sanitary knowledge among the people. At the same time it may be questioned whether the papers and the speakers were not at times a little above the heads of their lay audiences. In some instances local authorities have sent, as their representatives, subordinate inspectors and vestrymen, who, in their private capacity, are small tradesmen, to cull the scientific fruits spread before visitors at these gatherings. The composition of brandy was discussed, factory and workshops legislation, the sanitation of the Mosaic law, the medical inspection of schools, the codification of sanitary laws, and many other more or less recondite topics, so that a wide and varied field of interest was opened up to the zealous sanitarian. One speaker advocated the necessity of fixing a standard of carbonic acid impurity in factories, a point upon which future efficient control of such places appears to us to hinge. Among familiar names may be noted Sir Charles Cameron, Dr. Ransome, Dr. Thresh, Dr. Cameron (Leeds), Dr. Kenwood, Dr. Hope (Liverpool), and many others.

The Art of Writing Medical English.

THE average medical man has little power of literary expression. Hence, when he rushes into print, as often as not he bewilders his readers instead of enlightening them with his particular views and observations. Who is not familiar with the tangle of reiteration, bombast, obscurity, and confusion of utterance that marks the written effusions of the ordinary medical man? Some there are who continue through a long lifetime, with a perversity worthy of a better cause, to pour forth long-winded communications upon all kinds of topics. Bored of this type are often mild monomaniacs, and their names are known and carefully avoided by readers of the medical journals. At times, no doubt, they are able by their persistency to help forward desirable change in the special section of the community to which they belong. In much the same way the political man of one idea now and then

achieves some reform of value to the community: it may be after years of patient waiting. On the other hand the world of medicine can always boast of a few particular stars who have literary faculties of the first rank. Some of the most notable productions have perhaps been those addressed to lay readers. There are several scientific works of the present day that may be termed classics as regards their purity and felicity of style and diction. Fortunately, if a man have his facts and his reasoning carefully prepared, good style is not an absolute essential to successful publication. With the main mass of the profession inability to write well simply means that the art has never been cultivated.

A Remarkable Case of Nasal Obstruction.

OCCASIONALLY sensational incidents occur in medical and surgical practice, and it may be said of the following case, the notes of which are published in the current number of the *Scottish Medical and Surgical Journal*, that so far it may be regarded as unique. A Japanese workman in Singapore was brought to Dr. Keng with the history that three months before he bathed in a pond, and while doing so he suddenly felt something slipping into one of his nostrils. He made an effort to remove it, but failed to dislodge it. On looking into the left nostril, which was a little swollen, Dr. Keng could plainly see a black mass projecting from the superior meatus. A cup of water was accordingly held to the nostril, and in a short time the tail of a leech was seen projecting from the nostril and wriggling about in the water. The next question was, how to extract the leech. The tail was seized with a pair of old fashioned artery forceps, and the nostril was douched out with a solution of permanganate of potash. But the effect of this was only to cause the creature to contract more firmly, so another method had to be tried. The patient was, therefore, given some chloroform to inhale, a procedure which proved effectual, for in a few moments the leech, with the forceps attached, dropped on to the floor. The man had, in the course of the three months, during which the leech had located itself in his nose, lost a large quantity of blood. His weakness was, indeed, such that he was barely able to stagger into the author's surgery, and there is no doubt that had the leech not been extracted a fatal result might have ensued.

Motor Cars for Medical Men.

It would seem that practitioners in country districts are investing largely in motor cars, and judging from the number of letters published in a recent number of the *Autocar*, in which high approval and satisfaction are expressed by those who have adopted them, this mode of locomotion is evidently becoming more and more popular in the profession. Several advantages are claimed for the motor cars as compared with horse traction. Generally it is said that a car will go faster and further than any horse. will negotiate any reasonable gradient, and is always ready for use, while the doctor can dispense with the services of a man

to drive it, and the machine can be left unguarded if necessary. These are certainly useful points upon the question of expense. However further time is still wanted in order to draw a comparison, but, so far, after the initial outlay of about £165, a motor car, it would seem, can be kept in order and regularly used at a much cheaper rate than horses can be employed. The complaint that cars are objectionable from the smell and noise which they cause does not seem to have much foundation in fact. Altogether, then, a good deal of enthusiasm is at present being shown by those practitioners who have adopted "moting" as a mode of locomotion.

Public Analysis at Second Hand.

IN a leading article on the above subject which appeared in our issue of September 27th, we commented on the undesirability of plurality in public health appointments. Among public analysts we mentioned by name two who each held appointments to four vestries, and two more who acted in that capacity to three such authorities. In mentioning these gentlemen our object was merely to show that plurality existed by a simple statement of facts. It is hardly necessary to add that nothing was further from our intention than to insinuate that the analysts referred to were not perfectly efficient and conscientious in the discharge of their duties. Our criticisms were addressed to the system, and not to the officials who carry it into effect. It is conceivable that an analytical chemist pure and simple might hold more than one post as vestry analyst with advantage to everyone concerned. At the same time we see no reason to modify our general conclusion that plurality has been the bane of sanitary administration in the metropolis. A minute and exacting analysis, whether chemical or bacteriological, demands the personal element, especially when grave medico-legal issues are involved.

The Royal College of Physicians, Ireland.

THE annual general meeting of the College will take place on St. Luke's Day, October 18th, on which occasion the election of President and officers will take place. Dr. J. W. Moore will, no doubt, continue in occupation of the Presidential chair, and Dr. Athill and Dr. Craig will retain their positions respectively as representative of the College in the General Medical Council and as Registrar. The examiners under the conjoint scheme with the College of Surgeons will also be chosen, but in these there will be changes. In the evening the college will hold its annual dinner, and will entertain a number of distinguished guests.

A New-Fangled Poison.

THE first recorded case of poisoning by hydrofluoric acid was the subject of an investigation recently at New Cross. Our readers are aware that the specialty of this acid is its erosive power on glass, and the victim of this poisoning was a glass enameller, who seems to have taken the poison out of bravado. He died in a few hours, notwithstanding all that could be done for him.

The Hospital Matron Again!

THE situation of the medical staff at institutions where the matrons are placed on terms of equality with them, to the detriment of harmony and discipline, is one that no body of self-respecting men ought to tolerate. The matron is the head of the nursing staff, and as such is the subordinate of the Medical Officer. If an ill-advised code of regulations places it in her power to balk her hierarchical superiors with impunity, we may be sure that sooner or later, be it whim, pique, or mere bad temper, she will fall foul of that officer, leading to disorganisation of the service, and public discussions of the most deplorable futility. Judging from the report of a meeting of the governors of the Lowestoft Hospital, which is published in the *Eastern Daily Press*, a situation of this sort appears to have been brought about by the intolerable behaviour of the matron in regard to Dr. Walker, an old-standing member of the medical staff. The report in question is devoted to an unusually protracted wrangle, the upshot whereof was a resolution in favour of a committee of inquiry, Dr. Walker in the meantime holding over his resignation. So far so good, but we venture to maintain that unless allegations of positive misconduct are made against the medical officer, the plain duty of the committee is to call upon the matron to resign. We are aware that it takes two to make a quarrel, but whenever it becomes evident that there is a want of harmony, the subordinate must give way. The question is not one which can be discussed on its merits. The matron "cuts up rough" at some criticisms offered by the medical officer, and thereafter loses no opportunity of scoring off him in the wards and *vis à* the nurses, who, poor things, thus find themselves between the devil and the deep sea. We trust the Governors will deal with the matter in accordance with the dictates of robust common sense and teach those who are in charge of nurses that their first and indispensable duty is to keep in harmony with their hierarchical superiors.

The Army Medical Department.

IN our columns to-day the Director-General advertises his readiness to engage a limited number of civilian medical practitioners for temporary service in the Transvaal. The engagement is for six months' certain, and as much longer as may be found necessary, and the pay is to be £270, or at that rate per annum. It is probable that many candidates will offer themselves.

Fleas and the Transmission of Plague Infection.

THE rat, according to Hankin, is the animal by which plague infection is conveyed. But the question which has for some time exercised the minds of the plague authorities is: How is the disease transmitted from the rat to man? A good deal of evidence has lately been collected showing that the agent of infection is the flea. Fleas are said to infest rats which are dying of plague, and bacilli, corresponding to the plague bacillus, have been discovered in the

intestinal contents of fleas obtained from such rats. Again, fleas from plague-afflicted rats have been made the means of communicating the disease to healthy rats; all the experiments, then, undertaken to test this flea hypothesis, have tended to show, almost without doubt, that the flea plays a most important rôle in the dissemination of plague.

The Irish Preliminary Examination.

THE examinations of students who are desirous of commencing medicine in the coming session was held last week in Dublin. We understand that 64 candidates offered themselves and that 32, or exactly one-half, were rejected. Although this large "mortality" is by no means displeasing to us, because we desire that no boy shall enter upon the study of medicine without at least the rudiments of a gentleman's education, we call attention to the large percentage of rejections because it affords a complete answer to the Committee of the General Medical Council, which has devoted itself to throwing dirt on the Irish examination on the ground that it is too easy. We doubt that any university in the kingdom could show as strict a severity of the examinations required for commencing medicine as the Irish colleges do.

A New Use for the Dispensary.

WITH reference to our annotation of last week in which we protested against making the dispensary rooms the centre for distributing charity relief to miscellaneous paupers, the Council of the Dublin Sanitary Association has adopted the following resolution:—"That the Council having read an article which appeared in the *MEDICAL PRESS AND CIRCULAR*, of October 4th, 1899, headed 'A New Use for the Dispensary,' hasten to express their opinion that the proposal to distribute Poor-law relief from the several city dispensaries is fraught with grave danger to the public health, and should not for a moment be entertained by any sanitary authority."

Vaccination in Liverpool.

IT is worthy of note that the general increase in the number of vaccinations does not hold good in Liverpool where the returns for the first half of the year show a diminution equal to 22 per cent. on the figures for last year. This is the more remarkable in view of the fact that the "conscientious objector" was conspicuous by his rarity in that city. As the *Liverpool Mercury* observes, in a paragraph on the subject, it thus becomes apparent that even in the comparative absence of the conscientious objector a community may suffer from the adoption of a policy of mere domiciliary visitation. The matter is serious enough to merit the early attention of the Local Government Board and of the Guardians.

LORD ROOKWOOD last week handed over the Cottage Hospital at Hatfield, Essex, as a gift to the parish in memory of the late Lady Rookwood. Four hundred pounds have been raised by subscription among her ladyship's personal friends, to be set aside as an Endowment Fund.

Return of the Liverpool Tropical Expedition.

SURGEON-MAJOR ROSS and the other members of the Liverpool Medical Expedition on Tropical Diseases in West Africa, returned to this country on Monday. Although the Expedition had been at work only six weeks the results have proved most encouraging. The authorities at Sierra Leone have, on the advice of the Expedition, decided to use every means to exterminate the mosquito spreading malarial fevers. Major Ross is of opinion that other conditions are favourable to health in West Africa, there being a good water supply, and that if Europeans are careful both in their mode of living and house construction the inhabitants would have every chance of health. Despite the tropical climate, only one member of the Expedition, Mr. Austin, had suffered from malaria. He had slept for one night without mosquito curtains, and was thus infected, but was now convalescent. Dr. Ould, of the party, had proceeded around the West Coast in order to instruct medical officers as to the best method of treating the scourge. The opinion of the party was that the future of the West Coast was assured as soon as the Colonial authorities took steps to extirpate the virulent mosquito in the neighbourhood of the principal towns. Of course, years must elapse before the inland stations could be cleared.

St. George's Medical School.

CURIOSITY has been somewhat aroused by the announcement that St. George's is to have the patronage of his Grace the Archbishop of Canterbury on the prize-giving day. It is pleasant to see the Church lending its hand to the profession, and there has always been a kindly feeling between them since the days of St. Luke; although now and then the "physician" has been not altogether agreeable to the "Church." The Archbishop probably knows something of the history of the hospital of St. George. It does not owe its origin to the munificence of a liberal patron like Guy, or to such religious bodies as those to which St. Bartholomew's and St. Thomas's can be traced. St. George's owes its character to its connection with great surgeons and largely to the profession. The School of the Hunters was a great school, and rivalling it the School of Lane. They were independent of the Hospital in one way, but were rivals in another. When the Lane School founded St. Mary's and the Kinnerton Street School moved up into the present hospital, a different state of things arose, and it must certainly be of interest to the present staff of St. George's to see that they stand worthy of the reputation of their forefathers. It is well nigh impossible in these days for anything to live on the reputation of the past.

DR. TELFORD SMITH having been compelled to resign the office of Medical Superintendent of the Royal Albert Asylum, Lancaster, which he has held for the last six years, on account of ill health, and out of thirty-five applications, Mr. Archibald Douglas, L.R.C.P., Deputy Medical Officer, H.M. Prison, Portland, formerly Assistant Medical Officer, Royal Albert Asylum, has been appointed in his stead.

DR. LESLIE PHILLIPS, who has occupied the position of honorary surgeon to the Birmingham and Midland Hospital for Skin Diseases, has been presented with an address on his relinquishing the post.

Scotland.

[FROM OUR SPECIAL CORRESPONDENT.]

PROFESSOR SIR THOMAS GRAINGER STEWART.—We believe that Sir Thomas Grainger Stewart, although his health, it is gratifying to learn, has very much improved since summer, does not feel equal to the duties of his double professorship, those of the Chair of Practice of Medicine, and of Clinical Medicine in the Infirmary. No announcement of what arrangements have been made as to the carrying on of his work in the Edinburgh University and Royal Infirmary, but we suppose he will be granted leave of absence for a considerable period, and an outsider appointed as interim professor.

TYPHOID FEVER OUTBREAKS.—Several local outbreaks of typhoid fever have this autumn occurred in various districts round Edinburgh. Although the cases in some of these epidemics were fairly numerous the attacks have been up to the present of a mild character. As is usual, each outbreak has been attributed by some to infection through water, through milk by others, and both theories supported by much, but vague, evidence.

THE EDINBURGH ROYAL INFIRMARY CONTEST.—The contest for the vacant medical superintendentship of the Edinburgh Royal Infirmary promises to be very keen. It is too soon as yet to say who will constitute the candidates' list, but all sorts and conditions of men would appear to regard £500 a year and a house as a desirable prize, judging by what is rumoured as to those already in the field.

GLASGOW SOUTHERN MEDICAL SOCIETY.—The opening meeting of the Glasgow Southern Medical Society for the session 1899-1900 was held on Thursday last, when the following office-bearers were elected for the ensuing year:—Hon. President—William M Ewan, M.D., LL.D., F.R.S. President—Hugh Kelly, M.D. Vice-presidents—Thomas W. Jenkins, M.D.; William Watson, M.D. Secretary—John Frazer Orr, M.D. Treasurer—William M'Millan, M.B., C.M. Editorial secretary—Andrew Wauchope, M.B., C.M. Seal-keeper—John Stewart, M.D. Extra members of council—Robert Pollock, M.B., C.M.; Alex. C. M'Arthur, M.B., C.M.; Duncan M'Gilvray, M.B., C.M. Court medical—John Dougall, M.D.; Robert W. Forrest, M.D.; Arch. Brown, M.D.; Edward M'Millan, L.R.C.S. Edin. Representative to Victoria Infirmary—Chas. E. Robertson, M.D.

MEDICAL SOCIETY OF LONDON.

THE Opening Meeting of the Session took place on Monday evening last, when the President, Dr. F. Roberts, delivered the usual inaugural address, an abstract whereof we publish elsewhere. This was followed by a discussion on "Serum Therapeutics and Anti-toxin Treatment," initiated by Dr. Heron, who referred to the various experiences which he had published from time to time on the tuberculin treatment of tuberculosis and lupus by tuberculin, old and new. On the whole his results were decidedly encouraging, and neither in hospital nor in private practice had he ever seen any untoward results follow the use of the old or the new tuberculin. They had made upwards of 2,000 injections at the hospital without even a superficial abscess.

Dr. Washbourn followed with a disquisition on diphtheria antitoxin, anti-streptococcic serum and anti-pneumococcic serum. The former, he opined, had won its spurs. He pointed out that there were two classes of remedies, the antitoxin class which acted by annulling the toxins and the sera which prevented the growth of the living bacteria. In respect of the *modus operandi* of anti-toxin he endorsed Ehrlich's view that toxins and poisons generally produced their ill-effects by entering into a combination with certain molecules in the cells,

the antitoxin, by combining with the toxins, preventing the tissues entering into the combination, and so averting the harmful results. Certain tissues, however, had a stronger affinity for the toxins than had the anti-toxin, and so might form the combination in spite of the latter, and this explained why anti-toxin did not save life in all cases. He pointed out that patients who died in spite of the treatment all succumbed to symptoms indicative of paralysis of the vagus nerve. Admitting this explanation, he held out the hope that it might be found possible to prepare antitoxins from other animals than those at present employed, which would display an affinity for the toxins greater than that of the nervous system. With respect to the antistreptococcal serum, he insisted on the fact that no specimen thereof could be relied upon to produce beneficial results in all cases of streptococcal infection; it exerted marked effects in some cases, and none at all in others, and at present there were no means of distinguishing between the two sets of cases. He spoke less confidently about the anti-pneumococcal serum, which, though it was based on strong experimental proofs, did not as yet yield results sufficiently sure for him to express a decided opinion. He thought, however, that it merited a more extended trial in this country.

Dr. Hubbard made some interesting remarks on his experience with serum as a coagulating agent. He had tried it in two cases of aneurysm with the result of affording marked relief from pain, and the coagulating property had been very successful in arresting the loss in an obstinate case of menorrhagia. Finally, in a case of hæmophilic epistaxis, the injections had arrested the hæmorrhage after surgical measures had failed.

Medical News.

Charing Cross Hospital Medical School.

THE following entrance scholarships have been awarded:—The Livingstone Scholarship (100 guineas) to Mr. Philip Rees, the Huxley Scholarship (55 guineas) to Mr. R. Huxtable, and the Universities' Scholarships (each 60 guineas) to Mr. A. E. Taylor and H. F. Skrimshire. Entrance scholarships have also been awarded to Mr. L. Maitland (60 guineas), Mr. Harold Smith (40 guineas), and Mr. H. W. Farebrother (30 guineas).

University College, London.

MEDICAL scholarships and exhibitions have been awarded as follows:—The Bucknill entrance scholarship (for proficiency in science), value £30 a year for four years, to Mr. G. Hall; two entrance scholarships (for proficiency in science), value 55 guineas each, to Mr. A. Ferrière and Mr. E. Mapother; two exhibitions (for proficiency in anatomy and physiology), value 76 guineas each, to Mr. C. S. Parker and Mr. T. L. Llewellyn.

St. Thomas's Hospital Medical School.

THE University Scholarship (£50) has been awarded to Mr. Arthur Cyril Hudson, B.A., of Trinity College, Cambridge; the Natural Science Scholarship (£150) has been awarded to Mr. Lacey Bathurst; the Natural Science Scholarship (£60) has been awarded to Mr. Leonard Craske. Messrs. E. H. Burnett Bailey and F. A. Broadribb earned marks qualifying for a Scholarship.

London School of Medicine for Women.

THE following scholarships have been awarded at this school in connection with the Royal Free Hospital:—School Scholarship (value £30), Miss Sommer; Bostock Scholarship (£60 a year for four years), Miss Payne; Mabel Webb Research Scholarship (value £30 a year for two years), Miss Vaughan, M.D.B.S.

Guy's Hospital Medical Schools.

THE following entrance scholarships and certificates have been awarded:—Senior Science Scholarship, for University students, £50, Mr. P. N. Blate Odgers, Lincoln College, Oxford; and certificates to Mr. G. E. Malcolmson, Owens College, Manchester; Mr. F. H. Parker, Pembroke College, Cambridge; and Mr. H. Robinson, Trinity College, Cambridge. Junior Scholarships in Science, £150, Mr. H. F. Bell Walker; £60, Mr. J. H. Clatworthy; and certificates to Messrs. G. Russell,

and H. H. Carter. Entrance Scholarships in Arts, £100, Mr. F. Hood, Roan School, Greenwich; £50, Mr. H. S. Knight, Bancroft's School, Woodford Wells; £30 (Dental School) Mr. A. Black, Foyle College, Londonderry; and certificates to Mr. E. J. N. Aston, Jesus College, Oxford; and Mr. H. H. Watney, Trent College, Derbyshire.

St. George's Hospital Museum.

WE are requested to make known that the specimens added to the Pathological Museum of this hospital during the past year are, as usual, placed on view in the museum, and will remain on view during the month of October. As this is the first occasion on which it has been possible to show a large number of specimens preserved in formalin solution, with the natural colours preserved, members of other schools are invited to view them. The Curator, Dr. Lazarus Barlow, attends from one till four daily. The specimens number about 140, and a description of each is attached.

All Saints' Home.

THE Sisterhood of All Saints' Home, Margaret Street, who have had charge of the nursing of University College Hospital since 1862, having recently resigned, it was felt by the Committee that the very valuable services rendered by Sister Cecilia, who for twelve years had worked as a ward Sister, and for seventeen years had occupied the responsible position of Lady Superintendent of Nursing, should be recognised. The members of the Hospital Committee and the members of the medical and surgical staff accordingly assembled in the Board room of the Hospital on the 4th inst. and presented Sister Cecilia, on behalf of the All Saints' community with a copy of one of Raphael's "Madonna," to which was attached the following inscription:—"The Sisters of All Saints' undertook the nursing of University College Hospital in 1862, and for thirty-seven years devoted themselves to this work of charity. In grateful remembrance of their long association with the Sisterhood, the Committee and staff of the Hospital present to Sister Cecilia, who has been Sister Superior for seventeen years, this copy of a well-known picture by Raphael.

The Medical Sickness and Accident Society.

THE usual monthly meeting of the executive committee of the Medical Sickness, Annuity, and Life Assurance Society was held on the 29th ult., at 429, Strand, W.C. There were present: Dr. de Havilland Hall, in the chair; Dr. J. B. Ball, Mr. Wm. J. Stephens, Dr. J. Prikett, Mr. J. Brindley James, Dr. M. Greenwood, Dr. Alfred S. Gubb, Dr. W. Knowsley Sibley, Dr. F. J. Allan, and Dr. J. W. Hunt. The accounts showed the society to be growing in numbers and financial strength. During the summer a cash bonus of nearly £5,000 has been distributed, each member receiving his share, *pro rata*, of the surplus found to exist when the business was valued last year. The sickness during the summer had been considerably under their expectation, and there is little doubt that on the whole year the business will show, as usual, a considerable profit. The Medical Sickness and Accident Society makes a complete provision for those of its members who are permanently incapacitated, either by illness or accident. Under these arrangements over a dozen members of this Society whose affliction leaves little hope that they will ever be able to resume work are now drawing annuities averaging from fifty to one hundred guineas a year. It is felt that this is one of the most useful functions performed by the Society. Prospectuses and all other particulars from Mr. F. Addiscott, Sec., Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

West London Medico-Chirurgical Society.

THE Society held the first meeting of its eighteenth session at the West London Hospital on Friday, October 6th, when the President, Dr. J. B. Ball, delivered his inaugural address on "The Progress of Rhinology." The address was an interesting one, particularly to specialists on the subject, and we give a full *résumé* in another column under the heading of "Original Communications." After its delivery a vote of thanks, proposed by Dr. J. W. L. Thudichum and seconded by Dr. S. D. Chippingdale, was carried by acclamation. Dr. Ball briefly replied.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

REPRINTS.—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them, at half the usual cost, on application to the printers before the type is broken up.

DR. HAYWARD.—We are unable to deal with your communication in this number, but we hope to be able to do so in our next.

AN EDINBURGH STUDENT.—Regret we cannot answer the question; write to the publishers of the book, they will doubtless be able to give you information not in our possession.

L. K. Q. C. P. (Belfast).—The information given you is undoubtedly correct; it is the most up-to-date and sound "manual of surgery" extant.

MR. HATTON (Liverpool).—We think you have somewhat misunderstood the requirements; if you will re-read the advertisement in another column you will see that "civilian medical practitioners for temporary service with the troops in the United Kingdom" are required by the Government.

DR. Y.—There is no reason whatever why our correspondent should not charge for his visit.

GENERAL PRACTITIONER.—Paludism in infants is well known in certain parts of the world. It used to be very prevalent in Norway and Sweden, but during the last ten years a great diminution in the number of cases has occurred. The most marked symptom, noticed by Cronquist, was an intense periodical frontal headache developing in the early morning of each or every other day, lasting till mid-day.

DR. R. F. C.—Behring published as long ago as 1872 the results of his experiments with the diphtheria antitoxin, showing its value in immunising animals from and curing them of diphtheria. But it was not till 1893 that, in his "History of Diphtheria," he suggested that the remedy could be used for children.

DR. DUDGEON.—See reply to Dr. Hayward.

Meetings of the Societies and Lectures.

WEDNESDAY, OCTOBER 11TH.

HUNTERIAN SOCIETY.—8.30 p.m. Dr. Sansom: The Effects of Influenza on the Heart and Circulation, their Clinical History and their Treatment. (First Hunterian Society Lecture.)

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—4.30 p.m. Dr. M. Dockrell: Bullous Eruptions. (Post-graduate Course.)

THURSDAY, OCTOBER 12TH.

BRITISH GYNÆCOLOGICAL SOCIETY (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. Macnaughton-Jones, Mr. Charles Ryall, and others. Paper:—Mr. J. Furneaux Jordan (Birmingham): On the After-results of Operations on the Uterus and Appendages.

SOCIETY FOR THE STUDY OF INEBRIETY.—Quarterly meeting at 11, Chandos Street, Cavendish Square, at 4 o'clock. Dr. Harry Campbell, F.R.C.P., paper on The Craving for Stimulants.

FRIDAY, OCTOBER 13TH.

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8.30 p.m. Papers:—Dr. Rolleston: A Case of Acute Streptococcal Meningitis supervening in the course of Chronic Nephritis.—Dr. Churton: Aneurysm of the First Part of the Arch of the Aorta projecting into the Axilla.—Dr. F. J. Smith: A Case of Obstinate Anæmia in a young Girl associated with peculiar Tropic Disturbances and with doubtful Thrombosis of the Superior Longitudinal Sinus.—Mr. H. B. Robertson: Acute Intestinal Obstruction due to an Intussusception of Meckel's Diverticulum.

HOSPITAL REFORM ASSOCIATION (St. Martin's Town Hall).—4 p.m. Conference on Hospital Reform.

Vacancies.

County Asylum, Lancaster.—Assistant Medical Officer, unmarried. Salary to commence at £125 per annum, with a prospect of increasing to £250 per annum, with board, &c.

Hospital for the Insane, the Coppice, Nottingham.—Assistant Medical Officer, unmarried. Salary £150 per annum, with apartments, board, attendance, and washing.

Leicestershire and Rutland Lunatic Asylum.—Assistant Medical Officer, unmarried. Salary commencing at £150, with board, lodging, washing and attendance. Applications to the Clerk, 10, New Street, Leicester.

Lincoln County Hospital, Lincoln.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging and washing.

Metropolitan Asylums Board.—Assistant Medical Officers at the Fever and Small-pox Hospitals, unmarried. Salary commencing at £160 per annum, with board, lodging, attendance, and washing. Applications to the Clerk to the Board, Norfolk Street, Strand, London. (See advt.)

Parish of St. George-in-the-East, London.—Assistant Medical Officer for the Infirmary and Workhouse. Salary £120 per annum, with rations and apartments. Apply to the Clerk, Guardians' Offices, Raine Street, Old Gravel Lane, E.

Royal Hospital for Diseases of the Chest, City Road, London.—Resident Medical Officer for six months. Salary at the rate of £100 per annum, with furnished apartments, board and washing.

Royal Infirmary of Edinburgh.—Superintendent. Salary £500 per annum, with free house, coals, and light.

St. Andrew's Hospital for Mental Diseases, Northampton.—Junior Assistant Medical Officer, unmarried. Salary commencing at £150 per annum, with board, apartments, and washing.

Victoria University, Manchester.—External Examinership in Anatomy for three years. Applications for terms and other necessary particulars to be sent to the Registrar. (See advt.)

War Office, Army Medical Department.—Civilian Medical Practitioners, for temporary service with troops in the United Kingdom for a period of six months. Remuneration at the rate of £270 per annum inclusive. Applications to the Director-General, Army Medical Department, 18, Victoria Street, S.W. (See advt.)

Appointments.

DOUGLAS, ARCHIBALD R., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg. Resident Medical Officer to the Royal Albert Asylum for Idiots and Imbeciles of the Northern Counties, Lancaster.

EVANS, DANIEL EDWARD, M.B., B.S., M.R.C.P. Lond., M.R.C.S., Anaesthetist and Pathologist to the Swansea Hospital.

HALLAM, H., L.R.C.P. Lond., M.R.C.S., Assistant Medical Officer for the Workhouse of the Eccleall Bierlow Union.

HALL, H. S., L.R.C.P. Lond., M.R.C.S., Medical Officer for the Leigh Workhouse.

HAYES, A. HERBERT, M.R.C.S., L.R.C.P., House Surgeon to the East London Hospital for Children and Dispensary for Women.

INGRAM, A., M.B. Edin., L.R.C.P. Lond., M.R.C.S., Assistant Medical Officer for the Workhouse of the Aston Union.

JUKES, G., L.R.C.P., L.R.C.S. Edin., Medical Officer of Health for the Longridge Urban Sanitary District.

PARR, EDWARD JAMES, M.R.C.S., L.R.C.P. Lond., House Surgeon to the Torbay Hospital and Eye Infirmary, Torquay.

POWELL, C., L.R.C.P. Lond., M.R.C.S., Junior Assistant Medical Officer for the Wandsworth and Clapham Union.

RABY, L. M. D. Durh., M.R.C.S. Medical Officer for the First Sanitary District of the Devises Union.

SHELLEY, P. W. G. L.R.C.P. Lond., M.R.C.S., Medical Officer for the Cruwys Morchard Sanitary District of the Tiverton Union.

STOTHERLAND, D. SAGE, M.B., Ch.B. Glasg., Resident House Surgeon to the Cumberland Infirmary, Carlisle.

TUDD, G. D., L.R.C.P. Edin., M.R.C.S., Medical Officer to the Brook Dispensary, Selby.

Births.

BYRCE.—On Oct. 5th, at 54, Stroud Green Road, N., the wife of John R. Bryce, M.D., D.P.H., Barrister-at-law, of a son.

BUTTAR.—On Oct. 6th, at 20, Kensington Gardens Square, London, W., the wife of Chas. Buttar, M.D., of a daughter.

LOXTON.—On Oct. 4th, at 45, Belgrave Road, Edgbaston, the wife of Arthur Loxton, F.R.C.S., Edin., of a daughter.

REVELL.—On Oct. 4th, at 11, Granville Road, Southfields, S.W., the wife of Hugh Stanley Revell, M.R.C.S., L.R.C.P., of a daughter.

SAINSBURY.—On Oct. 3rd, at 63, Welbeck Street, London, W., the wife of Harrington Sainsbury, M.D., of a son.

Marriages.

SOUTHWELL-SANDER—HATCHARD.—Oct. 5th, at St. John's Church, Sandown, I.W., Gerald Southwell-Sander, M.B., C.M., of Wateringbury, Kent, to Emily Mary, eldest daughter of the late Henry Hatchard, Esq., of Walsford, Wimborne.

KINGDON-MEADOWS.—By special licence, at Saint Gabriel's Church, Willesden Green, Wilfred Robert Kingdon, M.B., B.S., of 44, Maitland Park Road, Haverstock Hill, N.W., to Florence Matilda, eldest daughter of James Meadows, of Cricklewood.

Deaths.

FENOULHET.—On Oct. 1st, at Blomfield Terrace, Paddington, John Henry Fenoulhet, M.A., M.R.C.S., L.R.C.P., aged 41.

HODGES.—On Oct. 3rd, at Addison House, Upper Edmonton, in his 42nd year, James Hodges, L.S.A., M.R.C.S. Eng., eldest son of the late Rev. James Hodges, of Shippon, Berks.

JACKSON.—On Oct. 1st, at Broadhurst Gardens, South Hampstead, Henry Ensworth Jackson, M.R.C.S., aged 52 years.

KELLET.—On Oct. 8th, at St. David's Road, Southsea, Surgeon-Major Ed. Young Kellett, A.M.D., aged 68.

LAWFORD.—On Oct. 2nd, at Oriol House, Leighton Buzzard, Edward Lawford, M.D., aged 79 years.

LILLIES.—On Oct. 3rd, at the Lawn, Shepherd's Bush, George William Lillies, M.D., in his 77th year.

WALLACE.—On Oct. 1st, at St. John's Terrace, Colchester, Alexander Wallace, M.D., M.A., Oxon., M.R.C.P., aged 70. Foreign and Colonial papers please copy.

THE CAUSES AND TREATMENT OF SCIATICA AND NEURALGIA.

By HERBERT W. G. MACLEOD, M.D., M.S.ED.,
Late Surgeon-Captain, H.M.I.M.S.

SCIATICA and other forms of neuralgia are generally believed to be due to a neuritis of the affected nerve, its branches, or its cords of origin. The pain of sciatica differs in character from that of supra-orbital neuralgia in being more constant, more easily excited by pressure, and in shooting less rapidly along the nerve. It is usually intense at the sciatic notch, behind the upper half of the femur, about the knee-joint, below the head of the fibula, above the outer side of the ankle, and on the dorsum of the foot.

When the pain is of a dull, gnawing character the patient frequently thinks he is suffering from "muscular rheumatism." When the diagnosis is doubtful, by flexing the leg on the hip and then pressing on the external popliteal nerve as it lies under the tendon of the biceps in the popliteal space, a sudden spasm of pain in the course of the nerve is experienced by the patient.

In doubtful cases I have been able to convince myself (and the patient) that the case was one of sciatica, by pressing deeply over the nerve below the lower border of the gluteus maximus near the origin of the long head of the biceps.

By flexing the thigh on the pelvis, and extending the leg, the characteristic shooting pain can be elicited, and a doubtful diagnosis cleared up.

The causes of neuralgia and sciatica are numerous, and all of them point to irritation of the affected nerve, either in its cords of origin, its course, or in its branches.

Interstitial and peri-neuritis have been observed. The nerve is swollen and reddened, and there may be marked exudation in its sheath, or in the interstitial connective-tissue. Endarteritis has been noticed by some observers in the nerve-sheath, but Horsley and Rose detected changes in the nerve-elements—none in the vessels.

Gout and rheumatism are stated to be predisposing causes, but the late Dr. Fagge agreed with Ainslie in thinking that "the relation of sciatica to rheumatism is altogether imaginary." Gout and syphilis may excite a neuritis, and so act as causes, and some observers believe the latter not to be a common cause of sciatica, unless spinal meningitis is present, or there is a lesion of the cord.

Among existing causes exposure to cold (especially when the body is heated), wet clothing, sitting on a damp seat, &c., are foremost. I recently had a patient under my care who got a severe attack of sciatica (for the first time in his life), when travelling on a cold and damp day in a tram-car.

Heavy muscular exercise may excite an attack, but I am inclined to ascribe it more to a resulting en-

feeblement of the system than to the exertion *per se*. Deterioration of health, anæmia, nervous depression, mental strain, overwork, &c., are all exciting causes.

It is stated that neurotic subjects are not liable to neuralgia, and that in the clinical history of "Neuralgia Major" strikingly few cases are found in hereditary neuropaths. My experience has been that neurotic people, especially nervous and hysterical women, are particularly liable to suffer from facial (supraorbital) neuralgia; and we know that cases of neuralgia show a preponderance of the female sex. It is the reverse in sciatica; and this is explained by men, from the nature of their work, being more exposed than women to the exciting causes of that affection.

There is one exciting cause of facial neuralgia, and of sciatica, which seems to be greatly underestimated. It is malaria. I was somewhat surprised to read in a well-known work on Medicine that, "although the distinct periodicity of neuralgia was supposed to indicate a malarial origin, this view no longer prevails"; and later on in the same work, "although malaria is considered to be a cause of sciatica, such cases, however, do not yield to quinine."

I feel sure that there are many who, like myself, have seen numerous cases of neuralgia (in Military and Civil practice in and out of the Tropics) due to malarial poison. I have noticed it in patients otherwise in excellent health. The only likely cause of their disease was exposure to malaria; and further, their symptoms were relieved by arsenic and quinine which are known to be efficient in such cases. I have in several instances been able to verify the following points:—

1. That the first attack may come on some time after the patient has left a malarial country or zone.
2. That in consequence, the cause of the disease is likely to be misunderstood.

3. That, whether residing in a malarial or non-malarial country, subsequent attacks are readily brought on in damp weather, after a heavy rainfall, and in a warm, moist, and enervating atmosphere. Rank vegetation also is an important exciting factor.

4. That attacks are most common in spring and autumn, and that a bracing climate and frosty and fine weather do not as a rule excite a paroxysm.

Neuralgia is supposed to be caused by toxic substances circulating in the blood, and irritating the sensory neurons; and one might suggest the malarial parasite as the *fons et origo mali* in persons who have been exposed to infection.

With regard to treatment: Quinine is very much used in all forms of the disease. If given in sufficiently large doses, and for a long period, it generally has a beneficial effect. Cinchonism should be guarded against by giving hydrobromic acid or sodium bromide. My experience of this drug in neuralgia and sciatica has, however, been disappointing; the effect is slow and not always sure.

Cinchonine has some effect, but in my limited trial of that drug, the results have fallen short of those of quinine. Ammonium chloride is much praised by some authorities who have used it successfully in facial neuralgia "of rheumatic character"; but Sir Thomas Watson said that if four doses (of half a drachm each) fail to give relief, the drug may be considered unsuitable for the case. Dr. Ringer in his classical work on "Therapeutics," states that eminently practical men require no new remedy, for they consider this salt rarely fails to give relief in all forms of neuralgia. Antipyrin, in my experience, has temporarily relieved the pain, but has not cut short the attack.

The drug on which I place most reliance is arsenic. After a fair experience of it, both in neuralgia and sciatica, I have come to the conclusion that it is the most uniformly successful remedy.

It will not agree with all patients, and must be commenced in small doses of about ℥ij. of the Liquor Arsenici Hydrochlor., for adults, given three times a day after meals. I have not found Fowler's solution so palatable as the former preparation, because the Tr. Lavand Co. in it sometimes causes nausea.

To prevent griping from the arsenic I have found a preparation of opium useful, and prefer Nепenthe to the Tincture, because it seems to cause little or no headache in persons who suffer from this distressing symptom when taking the tincture. With Nепenthe Liq. Arsenici Hydrochlor. can be used (an alkali is incompatible), and Sp. or Aqua Chloroformi. Tr. Aconiti in ℥ij. doses may also be added; the heart must be watched. It has often succeeded in relieving pain and shortening an attack. Liquor Sodæ Arsenicalis is also useful in sciatica.

Tr. Ferri Perchlor. has a great curative effect, especially in anæmic cases, but I have often found that it causes headache, dyspepsia, and a sensation of fulness with throbbing of the carotids and temporals. I therefore seldom employ it or other ferruginous compounds, unless specially indicated, and rely on arsenic.

Iron causes constipation when given as the tincture, and I am quite certain that a severe attack of facial neuralgia is markedly relieved after the bowels have acted well.

Arsenic acts as a mild aperient or laxative, and the dose of the Liquor should be gradually raised (if well tolerated) from one or two minims to ten minims two or three times a day after meals. At the first indication of intestinal pain, irritation of the eye-lids, &c., the dose must be at once reduced or stopped altogether for a few days, and then slowly recommenced in much smaller quantities.

I can recall a severe case of sciatica in an officer of a cavalry regiment, who was laid up for months, and was finally cured after a prolonged course of arsenic, when all other drugs had failed.

Heat locally applied and galvanism are useful adjuvants. The constant current seems to be more effective, or the two currents may be applied at the same time by means of De Watteville's key.

In severe cases acupuncture, Nélaton's cautery, or stretching the sciatic nerve are useful.

Instead of cutting down on the nerve and then stretching it, the same may be effected by flexing the thigh on the abdomen and then forcibly extending the leg. It is better to do this under an anæsthetic. Pressure on the supra-orbital nerve often relieves neuralgia, and a 20 per cent. solution of cocaine in Ol. Mentli. Pip. or Ol. Caryoph. is often effectual.

In severe and chronic cases of facial neuralgia surgical treatment may afford relief. The operation suggested by Professor Rose, of King's College Hospital, and the Krause-Hartley operation on the Gasserian ganglion have given satisfactory results.

In conclusion, I would suggest early employment of arsenic in all cases of sciatica and of facial neuralgia. The symptoms must be carefully watched. If, after a prolonged trial, the treatment fails, then other drugs should be tried. In chronic and intractable cases a surgical operation may be absolutely necessary.

COFFEE-GROUND VOMITING

AFTER

ANÆSTHESIA IN GYNÆCOLOGICAL AND OBSTETRICAL CASES

WHERE INSTRUMENTAL OR OPERATIVE INTERFERENCE HAS BEEN RESORTED TO. (a)

By Dr. OSCAR BEUTTNER,
Geneva.

DURING my term as assistant at the gynæcological clinic at the University of Berne, I was fortunate enough to observe six undoubted cases of vomiting of coffee-ground coloured substances and a seventh case presented itself to me in my practice at Geneva.

I have up to the present neither heard nor read of references to this phenomenon; but as I consider it important with respect to the question of differential diagnosis, I would claim your indulgence for a short span of time by bringing this, to my mind, important, phenomenon to your notice.

In one case chloroform and ether were the anæsthetics used; in five cases chloroform alone was used, and in one case ether alone. The chloroform was, as chemical analysis showed, of absolute purity; and there was no reason to doubt the chemical purity of the ether. In four of the seven cases the vomiting of coffee-ground coloured substances followed operative interference for difficult parturition, and in three after gynæcological operations. No abnormalities of digestive tract or of the heart was diagnosed in any of these cases.

I would like to dilate somewhat on the first of my cases, so as to convince you of the importance of recognising the phenomenon of vomiting of coffee-ground coloured substances with reference to differential diagnosis. The patient was æt. 43, and the operation performed was vaginal hysterectomy for cancer of cervix uteri. The anæsthetic used was chloroform, which was administered during thirty minutes by aid of cotton wool by means of a mask inhaler. On the patient becoming cyanosed ether was resorted to. The operation lasted two hours. During the same coffee-ground coloured substances were brought up per os, but without the muscular contractions induced in general by vomiting, the brownish masses flowing out of the mouth in a continuous stream.

After the conclusion of the operation ensued very protracted and violent vomiting of coffee-ground coloured substances, which consisted of altered red blood corpuscles, detritus and mucous cells. Who would not have thought that such symptoms were caused by a cancerous state of the stomach, and that in such a case the operation was entirely superfluous! My colleague, Dr. Muret, from Lausanne, told me that Professor Freund witnessed at the clinic in Strasbourg a similar case to the one just cited; the post-mortem examination revealed cancer of the stomach, which von Recklinghausen looked upon as primary (the cancer of uterus being also primary).

Happily in our case there was no cancer of the stomach, as the period of convalescence and the further sequel of the case clearly demonstrated.

(a) Paper read before the Amsterdam Congress of Gynæcology, 1899.

In a case in which a post-mortem was made I could verify that no coarse lesions are necessary for the production of vomiting of coffee-ground coloured substances; we only found numerous hæmorrhagic erosions in the neighbourhood of the pylorus. In another case in which an autopsy was made nine days after the operation we found very dark grey coloured masses in the stomach, but could not discern any pathological changes of the mucous membrane.

It would lead too far, to give in detail all the naked eye and microscopical appearances which presented themselves to me in each of the seven cases which have come under my observation. I will only hint at the most important ones, and shall publish detailed accounts later on.

As regards the etiology of this kind of vomiting we have not been able to arrive at a satisfactory conclusion; but it is evident that the stomach plays an important part as a hollow viscus, and having a peculiar arrangement of the endings of the smaller arteries and veins. It seems to be pretty certain that neither chloroform, nor ether, nor the manner in which anæsthetics are administered plays a direct etiological part. Venous stagnation, on the other hand, seems to be of great importance in this kind of vomiting.

The hæmorrhage into the stomach may attain considerable dimensions. This is easily proved by the quantity of the spontaneous vomit, or what may be brought out of the viscus with the stomach tube. The anæmic condition of the liver and spleen found at the post-mortem examination of the first case is thereby explained. The vomiting of coffee-ground substances may take place during the operation or immediately afterwards, or sometimes at a considerable interval after the conclusion of operative interference, after the application of an enema, or the introduction of the stomach tube.

A peculiar phenomenon is the change the blood undergoes after a very short time, as in a case I observed, where, after anæsthesia had proceeded for ten minutes, vomiting of coffee-ground coloured matter occurred. (The vomited masses of all my seven cases were microscopically examined and found to consist of altered red blood corpuscles, detritus and mucous bodies.)

In conclusion, if I am not able to give you a satisfactory result about my studies concerning the etiology of coffee-ground coloured substances, I have tried to interest you in this phenomenon, so as to prevent you from confounding the same with cases of cancer of the stomach, and also to increase the number of observers, who, by publishing details of cases under their observation, may help to enlighten us on this hitherto dark, but very interesting, symptom.

THE TECHNIQUE OF VACCINATION.

By COLIN CAMPBELL, L.R.C.P., M.R.C.S.,
Surgeon to the Workhouse and Public Vaccinator for
Saddleworth, Yorkshire.

THAT the recent Vaccination Act has enormously increased the details of the work of public vaccinators goes without saying—I should put it roughly that the pay has been doubled, whilst the labour has been quadrupled. The necessity of many of the new regulations may at first sight appear to be doubtful; but it is our duty, as faithful servants of the State, to carry them out to the utmost of our ability, to be carefully watchful of results, to discuss the subject amongst ourselves—with a view of being able to formulate and suggest to the Local Government Board such alterations and improvements as experience may show to be desirable to secure the highest standard of efficient vaccination.

To such an end I desire to offer a few observations on some doubtful points of technique.

The amended rules under which public vaccinators are now required to carry out vaccination are contained for the most part in Arts. 3, 4, 5, 6 and 7 of the third schedule of the General Order, and the first question is, the particular sort of lymph to be employed. Art. 3 says:—

“All public vaccinations are to be performed with glycerinated calf lymph, or with such other lymph as may be issued by the Local Government Board.”

This apparently means that public vaccinators are restricted—in public vaccinations, of course—to the use of N. V. E. lymph, and this interpretation is borne out by the wording of Form I. (notice of intended visit):—

“... I hereby give you notice that I shall visit _____, and shall offer to vaccinate it with glycerinated calf lymph, or such other lymph as may be issued by the Local Government Board.”

On the other hand, Article 4 inferentially permits the use of private supplies:—

“The Public Vaccinator . . . must not employ lymph supplied by any person who does not keep an exact record of its source.” Therefore he *may* employ lymph supplied by those who do keep such record.

But many private producers of lymph supply tubes containing, it is said, sufficient for two, three, or even five vaccinations. The General Order condemns this, but in somewhat ambiguous language. “When once he has unsealed a tube of lymph he must never attempt to keep any part of its contents for vaccination on a future occasion.” (Article 5.) The exact meaning of the word “future” appears to be open to doubt.

As regards the method of using lymph directed by Article 5, no one will cavil at a word. Most of the directions have long been carried out by public vaccinators—with perhaps the exception of the “artificial blower”—“blowing” being rarely needed when we used points, and had a regular succession of children.

The necessity for sterilisation and aseptic vaccinations, often in the midst of suspiciously septic surroundings, has necessitated a reconstruction on an elaborate scale of our armamentarium. Hitherto a lancet (or one of its substitutes), a basin of hot water, and a clean towel were all that was required. Even now we might sterilise and cleanse without heat, but for the blower. It is a great improvement, an obvious necessity, and if you have a nice one, much spilling of lymph is prevented. But it has a nasty trick of “sucking back,” and for its re-cleansing, nothing short of cold washing, followed by boiling, can be thoroughly sufficient. But as we cannot put our fingers into boiling fluid, we require a *forceps*; and we also want *scissors* to cut the lint or other material required for cleansing the skin and drying our instruments. As there is no real cleansing without *soap*, that is also required. So that our new “case” must include vaccinators blower, forceps, scissors, spirit-lamp basin, aseptic soap (some may desire antiseptic tabloids), lint, or gauze, and some means for protecting “the vaccinated surface against extraneous infection, both on the performance of the operation, and on inspection of results.” (Art. 6.)

This is a rule to which I desire to draw attention, for personally I am unable to conceive a way in which the italicised part of it can be scientifically carried out, unless we have some means of determining the atmospheric purity of the apartment in which the operation is to be performed. We make four abrasions, four doors through which potentially possible septic germs may enter. How can we scientifically keep them out—protect “the vaccinated surface against extraneous infection”? ?

The addition of glycerine to lymph adds a new difficulty. Fresh lymph dries as quickly as it is introduced, whereas the glycerinated lymph takes half an hour to dry, and so *seal* the abrasion.

Fortunately the dangers which the rule is designed to meet cannot be so real as an out-and-out advocate in the germ theory would have us believe. During 17 years' work as public vaccinator, I have not known a single case in which any troublesome symptoms followed on the initial operation, that is to say, in which symptoms of sepsis developed within three or four days.

And from my own experience, again, I would assert that in 99 cases out of 100 the unpleasant results which occasionally follow vaccination are caused either by the irritation of the vesicle after it has begun to form (by clothing), or by a premature dislocation of the scab, subsequent to "inspection."

To guard against these more real dangers the general order gives us very little assistance, except by directing that "Advice as to the precautions to be taken . . . shall always be given." It is easy to give advice, but difficult to ensure its being carried out.

The two objects which the public vaccinator aims at are: (1) Thoroughly efficient vaccination, and (2) the prevention of those unpleasant consequences which may cause suffering to the patient and also tend to bring the operation into disrepute.

The Vaccination Department of the Local Government Board has provided us with a lymph *capable* of giving the most perfect results. I believe that when failure follows its use a careful reconsideration of any individual case would reveal some slight error of procedure on the part of the vaccinator.

As to its reliability, my own statistics are perhaps worth recording. From January to April last I vaccinated 258 cases, with 256 perfect results. In four cases only was there any inflammation present at the time of inspection—almost invariably the eighth day. There were nine cases in which I was asked to see them after inspection, and found in all that the cause of trouble was premature rubbing off the scabs. Without troubling the section with statistics I may say that these 258 cases included 194 children, whose age varied from 1 to 14 years, and the worst arms were those of children between 1 and 6 years old.

But there is still a small percentage of "bad arms" even among children between four and six months. They are usually found in the dirty homes of the ignorant, thriftless classes. As regards the "one mark" question, the position in which public vaccinators and the better class of general practitioners generally are placed, is not only illogical, but utterly unreasonable. The law, in its wisdom, acknowledges as "successful" vaccination a "mark" of any size, however microscopic; whilst the Local Government Board directs—and probably every teacher of vaccination inculcates—the necessity of four marks! What is the position of a man trying to explain that four marks are *necessary*, when his listener *knows* that a certificate of "successful" vaccination under the Vaccination Acts can be obtained, perhaps, fifty yards off for the modest sum of sixpence—and one pimple?

But the difficulty does not end there. A large number of people regard a vaccination as good or bad, not by measuring the size of the vesicles produced, but by the presence or absence of all irritation, inflammation, or subsequent trouble of any sort. Well, if the *efficient* vaccinator must produce four pocks aggregating half a square inch, whilst the one mark man can also certify *successful* with one mark of $\frac{1}{16}$ ths of a square inch ($\frac{1}{16} \times \frac{1}{16}$), it would be an interesting calculation to estimate how many times more frequently *efficient* vaccination is

likely to produce what is regarded as unfavourable results than "successful" vaccination.

The consequences of this condition of things are far-reaching. It makes the position of the efficient vaccinator logically untenable, and is piling up future evidence against the utility of the vaccination laws.

The initial difficulty is the *glycerinated* lymph: it takes forty minutes to dry! Well, one cannot wait so long at every house. If you apply a pad of wood-wool or gauze *immediately*, I am satisfied that it sucks-up the lymph, and so spoils the vaccination. If you leave the application of the pad to others, it is applied awry, or too tightly, or too loosely, and so the vesicle is endangered.

Alternative applications for immediate use—discs prepared with gelatine or other non-absorbent material may be applied; but it is far from easy to secure their uniform adhesion. If a large disc, sufficient to cover four marks, be used, it usually wrinkles at its circumference and so becomes readily displaced; whilst smaller discs, designed to cover each separate mark, fail to adhere to the glycerinated surface and are usually on the day of inspection found far away from where they were placed. Occasionally a very pretty result is secured with both large and small discs, when the intelligent co-operation of the mother is secured.

Recently I have tried the application of flexile collodion—not exactly *immediately*. I have vaccinated, then packed up my case and filled up certificate, and at the last moment applied it. Nothing further has been applied till the day of inspection, when a gauze or wood-wool pad has been personally applied. I have examined several cases so treated, on the fourteenth day, and the results have been remarkably good.

In conclusion, I would say that in the perfection of our *technique* lies the surest hopes of perfecting our results. A box of vaccinator's instruments has been prepared at my suggestions by Messrs. J. Weiss and Son. In a large number of dwellings there is absolutely no space on which to lay out our instruments. My first object was to make the box or case, complete in itself, and no other space is required by the vaccinator, who has this box with him, than that which it stands on, and no other material than cold water.

ON EARLY DECAY OF THE TEETH. (a)

By J. KINGSTON BARTON, M.R.C.P.LOND.

SEEING that the enamel and dentine of the permanent teeth are formed so early in life, it is evident the factors concerned in the sound development of these parts of the teeth must produce their effects during the infancy of the individual.

The six-year old molars, or first permanent molars, are far on their way of formation even before birth, but the incisors and canines do not begin to consolidate until a few weeks after the child has been born. At three years of age most of the permanent teeth are well advanced. In the jaw of a six-year old child all the permanent teeth, excepting the wisdoms (third molars), are fully formed, saving the fangs. Hence, whether the child's constitution, or its infantile diseases, or the nature of its food, be the cause of good or bad teeth, in any case the effect is produced long before the seventh year.

This subject comes well within the scope of the Department of State Medicine, prevention being the guiding principle of this section.

It has been urged that School Boards should take

(a) Abstract of Paper read at the Section of State Medicine, Portsmouth Meeting of British Medical Association.

the matter up. But the expense of treating diseased teeth would be very great, and seems entirely for the well-to-do. The State can alone touch the subject by attending to the question of prevention. It would be far better and cheaper for the State to provide good cow's milk for all infants who could not get breast-feeding than to deal with bad teeth in children and young adults.

If bad teeth could be prevented the gain to the State and individual would be of enormous value, as it is wonderful how many diseases can be traced indirectly to bad teeth. The one condition that is chiefly responsible for bad teeth is rickets. The rich who are hand-fed all have rickets in a mild degree, and the poor almost all have it more or less severely. In the well-to-do the one common symptom of mild rickets is delay in the appearance of the milk teeth, and very few children cut their milk teeth at the proper time. Among the poor delayed teething and convulsions, bronchitis, diarrhoea bow-legs, and other well known manifestations show how numerous and prevalent are its symptoms.

Rickets is not a disease, but rather a diet disorder, almost entirely due to improper feeding, and the early use of starch, especially if insufficiently cooked, is nearly always the prime cause.

In India, and other warm climates where children live so much in the air, it is said they suffer but little from rickets. On the other hand, it is among these people that children are kept at the breast nearly two years, it being well recognised by the natives the deadly danger of infantile diarrhoea in a hot climate, and its associations with the use of animal milk. So it is the breast rather than the sun which prevents rickets.

For twenty years I have been observing the history of milk, and permanent teeth in infants and children developing under one's care. Also, inquiring carefully into the early feeding and health of growing children, young adults, and old people. Three facts come out very strongly as a result of these inquiries —

1. Breast-fed children always have the best milk and permanent teeth.

2. Those fed from the beginning with cow's milk, asses or goat's milk, come off second best.

3. Directly starch or any patent food comes to be added to, or given in place of, cow's milk, then almost for certain will the milk and permanent teeth turn out badly.

When a person between 20 and 30 years has excellent teeth, it will nearly always be found he or she had a good period of suckling followed by very simple feeding in the first few years of life.

If the first permanent molars are the only bad teeth, it is possible that the mother's health at the end of pregnancy was at fault, but errors in diet or disease in the very first months after birth will usually be found to have been the cause of such teeth being bad.

If the second or third molars are chiefly affected then errors of health and diet between five and twelve years will have been noted. In every case where, after fifteen years, the teeth were bad, then it is invariably found the child had neither breast nor simple cow's milk, but one or other of the patent foods came on the scene. Of these artificial foods, some are less injurious in their effects than others, but none are good. In the earlier years of condensed milk, I have notes which show that in a few cases it did not produce such bad teeth as one would have expected, but this does not hold good with most of the modern preparations. In the Westminster Hospital Reports of this year, appears an excellent article by Dr. W. A. Wills on the composition of modern Swiss milk, and other infant foods; also certain statements in Parliament of late, exposed the poverty of modern Swiss milk as a food substitute.

Many a modern child owes its life to one or other of the humanised foods, but I am sorry to say that the teeth of these children do not bear testimony to its being a perfect food. So there is some flaw in its composition the chemists have not yet satisfactorily overcome. Good as breast feeding is, yet it is not everything. For after weaning at nine months, until about three years of age comes the critical time when rickets is so rife. Hence, if after weaning injudicious feeding is adopted, then the last pre-molars suffer as also the bicuspid, with second and third molars of the permanent set; early breast feeding having generally ensured the success of the permanent incisors and canines.

In Scotland teeth are destroyed by too early use of oatmeal, some of the worst cases I have ever seen occurring in children who were given oatmeal from birth. In Ireland teeth are spoiled by too early use of potatoes, and in England by the early use of badly cooked flour and of bread. Until some teeth are cut the child should have nothing but breast or some animal's milk, the cow's for preference. By waiting for the appearance of teeth the pernicious system of pap foods can be avoided.

As each set of teeth (incisors, pre-molars, canines, and second pre-molars) appears, then further additions of egg, fish, vegetables, and selected fruits should be given until the milk set are complete, when meat may be added.

To bear out the above statements 100 consecutive cases of all ages have been taken from the note-books. A further separate account was taken of 100 cases over the age of 12. In these, 75 per cent. of good teeth had some form of breast-feeding. Of hand-fed cases, 75 per cent. had bad teeth, the remainder being good, or fairly good. In only one case was there loss of enamel, where the history showed good breast-feeding, followed by fresh country cow's milk, and no known severe infantile disease. However, in this case the teeth lasted very well in spite of the loss of enamel, showing the value of the early breast-feeding.

MEDICINE AND ITS STUDY. (a)

By J. W. MOORE, M.D.,

President of the Royal College of Physicians in Ireland.

AFTER some introductory remarks on the "nobleness of medicine," Dr. Moore passed on to

THE "MENS MEDICA"

of our profession, which on account of its dignity and responsibility should be approached with bated breath and reverent mien. I do not urge, he continued, that the physician should be an ascetic; the very solemnity of our work forbids this, and counsels reaction as a foil to the stern realities of our daily life. The best physician is the man who, daily witnessing the havoc wrought around him by the hand of Death, from his experience forms the habit of acting with a constant view to death, and develops the earnest desire to shield from its stroke the sick entrusted to his care. "Perception of distress in others," writes Bishop Butler in "The Analogy of Religion," is a natural excitement passively to pity, and actively to relieve it; but let a man set himself to attend, inquire out, and relieve distressed persons, and he cannot but grow less and less sensibly affected with the various miseries of life, with which he must become acquainted; when yet, at the same time, benevolence, considered not as a passion, but as a practical principle of action, will strengthen, and whilst he passively compassionates the distressed less, he will acquire a greater aptitude actively to assist and befriend them." This is the "mens medica," which endows the true physician with the God-like power of healing. His compassion, observation,

(a) Abstract of Address delivered at the inauguration of the Session of the Meath Hospital, Dublin, October, 1899

experience, reason, and learning are all enlisted in a self-denying and supreme effort to combat disease and to ward off death.

CLINICAL CASE-TAKING.

With much concern the physicians of the hospital have observed that for some years back—especially since the institution of a fifth year of medical study—students have been inclined to pay less attention to their clinical work than was hitherto their custom. They still “walk” the hospitals, but their attitude has become less actively attentive than of old. When it was not compulsory to “take cases,” cases were taken as they should be taken—that is, the patients were visited twice a day, and every symptom and turn of their illness were noted. Now, I do not for one moment wish to belittle the teaching in our schools of medicine. A liberal general education and a sound knowledge of the auxiliary sciences are essential elements in the evolution of the physician or the surgeon. But the paramount use of these aids to a professional training is to enable the medical student rightly to observe and study disease—and this crowning work of medical education can be pursued only at the bedside of the sick—there alone can “the ways of the sick” be learned. In my first address, delivered in 1875, I quoted Robert James Graves on this point. With your permission I shall quote him again. In his first introductory lecture after his appointment as physician to this hospital in 1821, he wrote:—“From the very commencement the student ought to witness the progress and the effects of sickness, and ought to persevere in the daily observation of disease during the whole period of his studies.” He continues:—“A great number of students seem little, if at all, impressed with the difficulty of becoming good practitioners; and not a few appear to be wholly destitute of any prospective anticipation of the heavy, the awful responsibility they must incur when, embarking in practice, the lives of their fellow-creatures are committed to their charge. It is by persons of this description that the earnest attention and permanent decorum which ought to pervade a class employed in visiting the sick are so frequently interrupted. Young men of the character to which I allude attend, or, as it is quaintly enough termed, *walk* the hospitals very regularly, but they make their appearance among us rather as critics than as learners—they come, not to listen, but to speak—they consider the hospital a place of amusement rather than of instruction. Students should aim not at seeing many diseases every day; no, their object should be constantly to study a few cases with diligence and attention; they should anxiously cultivate the habit of making accurate observations. This cannot be done at once; this habit can be only gradually acquired. It is never the result of ability alone; it never fails to reward the labours of patient industry. You should also endeavour to render your observations not only accurate, but complete; you should follow, when it is possible, every case from its commencement to its termination, for the latter often affords the best explanation of previous symptoms, and the best commentary on the treatment.”

In some degree, the languid case-taking of the present day is due to the active training of nurses and probationers which goes on in our wards. Our neat clinical charts are filled in by the probationers who are trained to take observations on the temperature, the pulse rate, and the rate of breathing. But this should not interfere with the case-taker's records—quite the reverse, for a second series of observations would control the first. Speaking with more than thirty years' experience as both student and practitioner, I assert with all the emphasis at my command that the student who neglects his clinical work, or carries it out in a half-hearted and perfunctory manner, will bitterly regret his lost opportunities in after life. Sooner or later, with much searching of heart and with many a misgiving, weighed down by a full sense of undivided responsibility, he will have to strive after that ripe experience which was within his grasp while yet a student, when he could share all responsibility with his teachers, and was sheltered beneath the ægis of their position.

After a brief reference to the advances made in medicine and surgery during the past quarter of a century, the lecturer alluded to

THE FEVER PROCESS.

The nature of the fever process is now far better understood than it was even a few years ago, and we have learned that “fever,” or elevation of bodily temperature above the standard of health, or “normal,” serves a useful purpose, provided that it is properly controlled. There is, in fact, what the Germans aptly call “das Heil-Fieber”—“the fever which brings back health.” At the close of an able address on “Antipyrosis” before the Tenth International Medical Congress at Berlin, in 1890, Professor Arnaldo Cantani, of Naples, used the memorable words, “Das Fieber, das in so vielen Krankheiten der beste Verbündete des Arztes ist”—“the Fever, which in so many diseases is the best ally of the physician.” Fever, in a word, purges the system. In an excellent article on “Typhoid Fever,” written in the present year, Drs. Affleck and Ker, of Edinburgh, say:—“The ordinary fever of a typhoid case runs such a fixed and definite course that it is hard to believe that the pyrexia is not nature's cure for the disease.”

In this mixed assembly of laymen and members—actual or presumptive—of the medical profession, I would raise a warning voice against the pernicious doctrine that in fevers the temperature must be reduced as quickly as possible to what is popularly called “normal.” It cannot be too often or too emphatically and authoritatively declared that such a procedure is very likely to destroy life. The so-called antipyretic medicines, or heat-reducers, should never be used by unskilled hands. The employment of such remedies, even by the skilled physician, calls for the utmost caution and the most anxious consideration. The danger lies in an interference with the production of body-heat, while the escape of heat from the system is increased. In this way collapse is likely to be induced. For many years I have taught that the only safe antipyretic, or assuager of fever-heat, is water, and especially cold water. It helps the escape of heat from the body in many ways, while it does not interfere with heat production, rather, indeed, does the use of cold water internally and externally encourage the evolution of heat in the body.

ALCOHOLIC STIMULANTS IN DISEASE.

Another popular error, rife among medical students also, is that alcoholic stimulants are a sheet-anchor in serious disease. Such a notion may be fraught with grave consequences—immediate and remote. A patient, already suffering from the effect of a specific poison, may be doubly poisoned by alcohol, itself an intoxicant, or poison. And—a still greater disaster—a habit of alcoholism may be engendered through the careless administration of alcoholic stimulants. Children and women, as a rule, bear stimulants badly, and in their case especially their use should be but temporary: In so-called “nervousness,” nervous depression and sleeplessness, stimulants are much more likely to do harm than to do good. If they are given at all, it should be under the watchful supervision of the physician, the effect of each dose being carefully noted and weighed.

The question of the administration in fever of these powerful drugs—for such they are—is an anxious one. The chief indications for their use are derived from the state of the pulse, the heart, the tongue, and the brain and from the presence of complications, particularly of the “typhoid state,” or that state which betokens profound depression of the nervous and muscular systems. Stimulants are most urgently required during the night and in the early morning, when the life-tide is at the ebb and the vital powers are wont to flag. In the forenoon they are much less needed. A comparatively safe way of exhibiting stimulants is in combination with food, in the form of egg-flip, wine-whey, sillabub, and so on.

DIET OF THE SICK.

This leads me to remark that, if you wish to be a good physician, it is necessary that you should also be a good cook. At all events, you should be a good theoretical

cook, effect being given to your theory by a good practical cook. There is scarcely a disease in which diet does not play a more important part than mere medicines. Again, there are no two patients whom precisely the same dietary will suit. We might say: *Quot homines, tet epulæ*. The skill of the physician will at times be severely tested in the attempt to draw up a suitable bill of fare for a fastidious patient. We should always remember that "what is one man's food is another man's poison." Dr. T. King Chambers, in his excellent "Manual of Diet in Health and Disease" (published in 1875), reminds us that when the tailor in Laputa sternly refused to take the usual measurements, and insisted on constructing Captain Gulliver's coat, waistcoat, and breeches on absurd principles, the customer voted it was the worst suit of clothes he ever had in his life. Dr. Chambers adds: "We should certainly fail in the same way if we did not take the measure of numberless contingencies in the daily life, and numberless peculiarities in the persons of those who consult us about their diet and regimen."

PULMONARY TUBERCULOSIS.

The hospital treatment of consumption—by which is commonly understood pulmonary tuberculosis—is an anxious question, and one that is difficult of solution. Year by year the conviction grows stronger that in treating this fell disease in the wards of a general hospital we are committing a grave hygienic error.

In an address on the "Prevention and Cure of Tuberculosis," delivered before the Section of Medicine at the Carlisle meeting of the British Medical Association in 1898, I pointed out that, theoretically, the air of a hospital ward, however clean and well-ventilated that ward may be, is unsuited for a consumptive. In it his surroundings are calculated to depress. The dietary may not coax his appetite. And then to look at the question from the point of the other patients, the presence of the consumptive may be no more than tolerated. He keeps them awake at night with his hacking and racking cough; he resents open windows, yet may pollute the air in the ward to an extreme degree. If his expectoration is not destroyed or disinfected, he may even infect his fellow-sufferers with his own disease. (a) He occupies month after month a bed which otherwise would accommodate many generations of patients labouring under less chronic and more curable maladies. Lastly, the hospital treatment of tuberculosis breaks down because of its utter inadequacy to cope with so universal and so tedious a disease. In a week every bed in every hospital in the United Kingdom might be filled with consumptives, and even then thousands upon thousands of cases would be left without hospital accommodation, so widespread is the plague of phthisis.

The hospital treatment of tuberculosis should resolve itself into providing of—

1. Consumption hospitals, or sanatoria, in which the disease could be treated in its earlier and more hopeful stages.
2. Special consumption wards in general hospitals, into which tuberculosis, and that disease alone, should be received.

3. Refuges for those far advanced in, or dying of, consumption. The German name for such an institution is very expressive—"Friedensheim," or "Home of Peace."

The providing of special wards in, or adjacent to, our general hospitals would meet to a certain extent some of the objections I have advanced to the treatment of consumption in hospitals. In such wards consumptives in a more advanced stage of the disease could be treated, the separate principle being carried out wherever possible, a ward in any case being planned to contain never more than three or four patients, and provision being made for inhalations of ozonised oxygen, as suggested and carried out by Dr. Ransome.

MEDICAL ETIQUETTE.

I do not wish to weary you with a long address, but there is one fact which, if once pressed home, may save

you and others from many a heart-burning in your professional life. A physician or a surgeon has no vested right or property in a patient. To put it in another way, the public have the most absolute right to choose their own medical attendants, and to change them as often as they please. Therefore, do not pick a quarrel with a professional brother on the ground that he has superseded you, and do not judge him harshly, or at all, until you have heard both sides of the question.

Do not misunderstand me. While the public must be left free-handed in this matter a serious responsibility rests upon every member of our profession who does not act towards his professional brethren with consummate tact, consideration, and forbearance. Never take advantage of a brother. If you are called in to visit a patient hitherto under his care, acquaint him of the fact with the least possible delay. Come to an honourable understanding with him. Do unto him as you would he should do unto you. If he then takes umbrage the fault lies at his door, not at yours. Such is "Medical Etiquette." William Stokes concluded one of his eloquent addresses on our conduct towards other men with the words of Hamlet, "Use them after your own honour and dignity; the less they deserve the more merit is in your bounty."

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, OCTOBER 13TH, 1899.

Sir R. DOUGLAS POWELL, Bt., President, in the chair.

ACUTE STREPTOCOCCAL MENINGITIS SUPERVENING IN THE COURSE OF CHRONIC PARENCHYMATOUS NEPHRITIS.

DR. ROLLESTON described the case of a man, æt. 22, admitted on the eighth day of his illness with a temperature of 103 degs., but without any definite evidence as to the nature of his illness, which had begun with tonsillitis. He was quite free from headache on admission, but the next day had two fits, passed into a condition of cerebral irritation, and died within 24 hours. The autopsy showed extensive purulent meningitis, due to streptococci infection, and an acute nephritis on the top of chronic parenchymatous nephritis. No streptococci were visible in microscopic sections of the kidney, so the acute renal changes may have been toxic. But, inasmuch as cultures were not made from the spleen or heart's blood, it could not be certainly said that the streptococcal infection was confined to the meninges of the brain. Terminal infections in renal disease were known to be common in the lungs, pleura, and pericardium, but not in the meninges. In Flexner's statistical study of terminal infections in chronic heart or kidney disease, the few cases of meningitis that occurred were almost always due to pneumococci. Flexner had shown that in chronic renal disease the bactericidal power of the blood was diminished and that terminal infections were therefore very liable to occur. This case was remarkable for the unusual site of the terminal infection, and for the latency of the meningitis. The tonsils were possibly the source of infection.

DR. F. J. SMITH commented on the rarity of such cases of which he had not met with an example in the post-mortem room. He remarked as curious that purulent meningitis so rarely followed renal disease, though pericarditis and pleurisy were common. He was surprised that the streptococcal infection could not be traced seeing that in tuberculous meningitis infection had been known to take place through the tonsils of which he mentioned an example.

ANEURISM OF THE FIRST PART OF THE ARCH OF THE AORTA PROJECTING INTO THE RIGHT AXILLA.

DR. T. CHURTON (Leeds) related the case of a man, æt. 53, admitted June 15th, 1898, with a painful swelling on the right side of the chest, extending from the mid-axillary line to the nipple line, half the size of a cocoon, the seat of well-marked expansile pulsation. First

(a) Geo. Allan Heron. The Relation of Dust in Hospitals to Tuberculous Infection. *Lancet*, Jan. 6th, 1894.

noted two years ago, he only left off work three months ago on account of pain in the right arm. Had been confined to bed for a fortnight, he was feeble, and had anginal attacks. Aneurism was diagnosed. An aortic regurgitant murmur was heard over the fourth costal cartilage. Syphilis was denied. It had been thought by a surgeon to be of axillary origin, but a resident believed it to be aortic, the diagnosis turning upon the effect of pressure upon the subclavian artery. On palpation, however, a slight heaving could be felt from the tumour to the sternum and this area was dull. The heart's impulse was felt in the sixth space, 1½ in. external to the left nipple line. The bruit was fine and whiffing, not suggesting a large regurgitation. No other marked pressure signs. The patient died on July 5th with symptoms of internal hæmorrhage. Post-mortem—the heart was enlarged, chiefly the left ventricle, the mitral valve was normal, the aortic cusps were rather thick, but presented no marked deformity. The cavity was not much enlarged, but the muscle was thick. The first inch of the aorta was fairly good, but beyond, it was greatly dilated, even within the pericardium. Beyond the pericardial attachment the first part bulged outwards and downwards. Just outside the pericardium on its outer aspect was a long narrow slit leading into a sac measuring 5½ x 4½ x 3½ inches, having a thick lining of solid clot. At the upper and inner part of the sac was a small opening ¼ in. in length, from which blood had escaped into the pleura at the upper and posterior part of the thorax. The third and fourth ribs appeared to have been broken in the anterior axillary region, and the remains of the broken and separated parts are apparently contained in the wall of the sac. The ribs were intact as to their outer surfaces for two or three inches. The aneurism lay wholly in front of the lung, the inner face of the upper lobe being closely adherent thereto. He pointed out as an unusual feature the point of projection of the aneurism into the right axilla, of which he had been unable to find another example.

Dr. F. J. SMITH raised the question whether a bruit afforded any estimate whatever of the amount of regurgitation. As the result of combined clinical and post-mortem work he thought it was quite impossible to tell the amount of freedom of regurgitation by other than clinical symptoms. He asked what was the weight of the heart, and pointed out that unless the valves were affected an aneurism of the arch or descending aorta had no effect in producing hypertrophy. The position of the aneurism, he opined, was merely an anatomical accident.

Dr. CHAPMAN referred to Gross's dictum that as regards an aortic regurgitant bruit, if the second sound far exceeded the first in length this would indicate extensive regurgitation, but this did not hold good as regards the mitral valve.

Dr. ROLLESTON, in respect of the significance of such murmurs, observed that there was a difference between a mitral and a regurgitant aortic murmur. In the former there was little relation between the loudness of the murmur and the extent of the lesion, but with an aortic regurgitant murmur, though there were noteworthy exceptions, there was a very fair relation between the distinctness of the murmur and the character of the lesion. He agreed that in the absence of heart or kidney disease aortic aneurism did not lead to hypertrophy of the heart.

Dr. PERCY KIDD agreed as to the unimportance of a murmur *quæ* the amount of regurgitation, but this could be estimated by reference to the pulse and to the presence or absence of the second sound over the aorta and the carotids. Perforation in this site was uncommon, but he had in his wards a case in which the perforation seemed to be posterior, the patient presenting a pulsating tumour over the scapula. In this case there was granular kidney.

The PRESIDENT said it was remarkable what an amount of absorption of ribs and other bones could take place without entailing suffering. He recalled the case of a patient who had an aneurism pulsating through the back of the scapula, who had complained of no particular suffering. He agreed that a bruit gave com-

paratively little information unless taken in association with the valve function. He asked whether the tracheal tug had been noted.

Dr. CHURTON, in reply, said it had been definitely settled in a discussion last year that hypertrophy of the heart was not a necessary consequence of aneurism. He referred to the case of a boy with a severe aortic regurgitation murmur, who presented two special signs which he considered indicative of grave regurgitation, viz., obvious enlargement of the heart downward and to the left, and instead of its being best heard over the fourth left costal cartilage it was loudest over the fifth and even the sixth, and a needle passed in through the fifth cartilage, went through the base of the conical channel which leads to the pulmonary valve in front and to the aortic valves behind. The kidneys in this case were reported to be slightly affected.

Dr. FRED J. SMITH showed a case of apparently

SIMPLE ANEMIA

in a young girl, æt. 19. First under observation in 1895, improved under iron. In 1896, while taking large numbers of Bland's pills, developed features of peripheral neuritis. In 1898 she suffered from warts on one hand, which showed peculiar phenomena of growth and decay. In 1899 she became much worse, and was admitted with a grave degree of anemia, and while in hospital developed most peculiar nervous symptoms consisting of (1) a prolonged condition of serious interference with the respiratory mechanism, with periods of hours of rapid breathing (66 or more per minute), alternating with hours of very slow breathing; (2) intermittent fits of unconsciousness with convulsive movements of face and right arm and leg. No treatment seemed of any avail, but the patient gradually improved until headache and pain in the legs were her only complaints. Incisions down to the bone of both tibiae relieved the latter; nothing has touched the former. Dr. Smith summarised the points of interest in the case as follow:—(1) its extreme intractability; (2) nervous phenomena, apparently peripheral; (3) nervous phenomena, apparently of central origin.

Dr. KIDD, who had seen the case in hospital, said it was a very puzzling case, and he had been inclined to fall in with the original diagnosis.

Dr. NORMAN DALTON said that until this year he would have been inclined to think that thrombosis was rare in anemia, but in December last he made the post-mortem of a young woman who had been suffering from anemia, and had died with cerebral symptoms. He found extensive thrombosis of all the sinuses extending into the *venæ galeni*. Some months later a young woman with marked anemia complained of pain in the arm and they found the veins of the arm thrombosed right up. During the present week he had seen a case very much like the one related by the author, but at an earlier stage. The patient, a woman, æt. 23, complained of persistent headache, which was entirely localised to the longitudinal sinus. There was numbness of, and movements in, the left arm. He pointed out that in this case, as in so many other cases of anemia which did not yield readily to treatment, there was a suspicion of inherited syphilis.

Dr. ROLLESTON asked what was the tension of the pulse during these attacks? He thought that in some ways this remarkable case read something like Stokes-Adams' disease. He asked whether there was much constipation?

Dr. SAVILL recalled the case of a boy, æt. 15, who was extremely anæmic, and had a little oedema around the ankles, and a persistent loud double murmur over the heart with intermitting temperature. He died of asthenia and post-mortem nothing was found until they opened the head, when at each corner of the longitudinal sinus an unmistakable gumma was found. They then examined the eyes and found striae in the cornea. On examining all the bones they were rewarded by finding gummatous masses, so that undoubtedly it was a case of congenital syphilis.

Dr. C. BOX referred to a case under Dr. Payne, supposed to be suffering from pernicious anemia. The red corpuscles were reduced to considerably under a million, but there was also a great increase in the eosinophile

cells. Subsequently a small serpiginous ulcer was seen on the palate, and the patient improved at once under iodide of potassium. Another case was examined for signs of syphilis, and some thickening of the tibiae was made out. Examination of the blood showed no increase in the eosinophile cells. The patient died, and the ordinary signs of pernicious anemia were found post-mortem.

Dr. SMITH, in reply, admitted that the possibility of syphilis had not occurred to him, but that he would take care that it was now inquired into. When she was at her worst the pulse was very small—asphyxial. Her temperature averaged about 97, though she had two days of unexplained pyrexia.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, October 15th, 1899.

ADENOMA OF THE INTESTINE.

INDEPENDENTLY of adenoma of the rectum described under the title of polypus, there exists an affection, very rare, it is true, in which the adenomata are not localised in the rectum but extend to all the surface of the large intestine called by M. Quénu, who made a study of the disease, polyadenoma. According to the author the neoplasm appears first on a relatively healthy portion of the mucous membrane, contrary to the opinion of Rokitsansky, who pretended that it took its origin from ulcerations caused by chronic dysentery. The co-existence of polyadenoma and cancer is relatively frequent, since out of 42 cases observed by M. Quénu 20 were found to have been the seat of both diseases. Polyadenoma would seem to be rare in children. Statistics show that more than one half of these cases were observed between 16 and 31 years of age, and twice more frequently in man than in woman. The malady presents three principal symptoms, diarrhoea, hæmorrhage, and painful phenomena; later on the general health suffers. The diarrhoea is very abundant, from fifteen to twenty evacuations in the twenty-four hours, and resists all medical treatment.

Sometimes the evacuations are mixed with blood and mucus, at others they are exclusively composed of mucus more or less stained with blood. At times no pain is complained of, but in general the patients suffer from violent pain in the abdomen and along the sides.

The diagnosis is difficult as it is necessary to bring the intestine to view by laparotomy as performed more than once by Czerny.

If, however, the finger is passed into the rectum it will generally perceive a series of polypi soft and pediculated, varying in volume between the size of a pea and that of a cherry along the walls of that portion of the intestine.

As to the treatment, it is necessarily unsatisfactory. Surgeons have ablated all the polypi within their reach through the anus with considerable benefit, especially as regards the hæmorrhage, but resections of the intestine were prevented by the anæmic conditions of the patients.

Yellow Fever in America.

THERE have been twenty-seven fresh cases of yellow fever, with two deaths, at Key West; one case (fatal) at Jackson; and five cases, with one death, at New Orleans.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, October 14th, 1899.

TUBERCULIN SOAP.

At the Münchener Naturforschende Versammlung, Hr. P. G. Unna read a paper on this new form of soap. The strain and stress period of tuberculin had, it was to be hoped, so long passed that when the speaker proposed a new form of it it would meet with a cool reception, but one free from prejudice. Scarcely any remedy had ever been used so lavishly, to be, in a short time, so completely neglected as tuberculin. Both the lavish use and the neglect were equally undeserved, and it appeared to him time that the experimental therapist, as well as the practitioner, should become masters of this wonderful specific, without expecting from it more than it could do.

Under the personal influence of Koch himself the administration of the drug had never ceased in the Infective Institute in Berlin, but elsewhere it was scarcely used except in veterinary medicine. This was not because physicians had not seen good effects from it; the reason probably was that people had not found the absolute radical effect that had been hoped for, and also partly that people believed that its benefits must be paid for by dangers to other organs, and to the life of the patient, and that the use of it was always to be associated with subcutaneous injections, general effects and fever.

As regarded the first prejudice, the remedy could not be allowed to fall out, because Koch, in the first joys of discovery, did not at once recognise its limits. The speaker could not name a single powerful remedy from morphia and chloroform to quinine and mercury, the sphere of action of which had not at first been overestimated.

It was the general body of the profession that expected more of tuberculin than it could do, for Koch had from the first emphasised the fact that tuberculin could not kill the tubercle bacillus. From this the practised dermatologist had taken the conclusion that neither lupus nor any other disease produced by tubercle could be cured by *tuberculin alone*. The chief reason for the neglect was, however, the danger of tuberculin. He, like many other physicians, had soon gone back to very small doses of tuberculin, and he held gradual cautious tuberculinisation with the smallest possible doses when it was only one factor used along with other well tried means, to be a comparatively safe method of treatment, at least for external tuberculosis, so long as its limits were kept in mind, and the period of time not put off in which the other remedies should be made use of. The use up to now of tuberculin injections involved a general action that, in the case of external tuberculosis, was quite unnecessary, and this could be replaced with advantage by a local tuberculin treatment. By such local use the dosage could be varied from place to place, corresponding to the degree of disease without the need, or thought for, any unnecessary or troublesome constitutional effect.

There were in general two ways by which medicaments that did not attack the skin could be made to find entrance through the cutis. They were mixed with either salicylic acid, resorcin, or other similarly active

phenol in the form of ointment, or with strongly alkaline soap. In both cases the skin was so opened up by these adjuvants that the remedy could act on the changed papillary body, and even on the deeper lying layers of the skin. The first experiments with tuberculin showed that salicylic acid caused precipitation, but an alkaline soap did not. The direction of his investigation was therefore decided, and after half-a-year's use on over thirty patients he had seen no reason to depart from the first selected form:—

Sapon. unguinosi, 10·0;

Tuberculini, 0·5—1·0—2·0 M. ft. ointment soap.

Here, as in all similar cases, the *sapo unguinosus* had shown itself the mildest yet the most energetic of all kinds of soap medication. The method of use was that used for all ointment soaps. A small quantity of soap (about 0·025 gm.) was used for the square centimetre rubbed in with the finger, which could be covered with a glove or protection, until its dryness prevents any further rubbing. Then the finger was wet with water, and with further rubbing it froths until it becomes dry again. Then the finger was wet again, and so on for four or five times until the whole had found its way out of sight below the horny layer.

As the ointment soap had a decided effect on diseased surfaces it seemed proper in the first experiments to treat a symmetrically lying spot in a similar manner with simple ointment soap instead of tuberculin soap. The difference of action between the two was as marked as could have been wished. With the tuberculin soap after 6, 12, 24 hours a slight prickling began, then an inflammatory hyperæmia with œdema that sometimes went on to formation of thick scales and crusts, and after a few days went back, but more quickly under the use of drying material, such as zinc sulphate paste. Then the lupus surface showed paler, softer, smoother than before; a portion of the *plasmom* had disappeared, and, more striking still, a portion of the fibrous growth which reacted to tuberculin like cellular lupus tissue, and which should not be confounded with lupus *icatrix*. It was just this lupus fibroma that caused the disfiguration of long treated lupus of the face, it caused the ectropium of the eyes and lips, closure of the nose and mouth, &c., in short, which caused the greater part of the hateful residua that so pitifully disfigured cases of half-cured lupus. If he then said, "Koch's treatment had, in the first place, a highly satisfactory cosmetic effect, and that through its specific absorbent action on lupus fibroma," he could now add that the same satisfactory cosmetic result could be obtained in a much simpler way, by the application of tuberculin soap. If the remedy did no more it deserved to keep a place in the dermatological armamentarium. But tuberculin soap did more. What was to be expected of it was the removal of diffuse lupus tissue, not that of the bacilli-containing lupus centres. The number of lupus centres after treatment with tuberculin soap was greater than with tuberculin itself, the recurrences more prompt and energetic. Surgical treatment must therefore be promptly applied where a radical cure was wished for.

On the other hand the tuberculin soap treatment had two essential advantages over all other—it acted quickly and almost painlessly. The quickness depended in the first place on the thickness and dryness of the upper layer; if this was considerable, it was well to apply

moist heat over the soap application, and to leave it on. It was less dependent on the mass of lupus, as the reaction was in proportion to the amount of tubercle, and in the same way on the disappearance of it, so that hypertrophied forms of lupus did not require a much longer time than the smooth and partially healed cases. More important for a rapid result was the percentage of tuberculin in the soap. In order to keep the reaction within bounds it was well to reserve the 20 per cent. strength for circumscribed cases, and more extensive cases to treat with the weaker 10 per cent. strength. In the latter case, it was well to divide the diseased areas into divisions the size of a shilling, which could be treated uninterruptedly and alternately with the soap and some drying material. This mosaic way was specially suitable for ambulatory practice. The period of treatment depended on the conditions named, and varied accordingly to extent and situation between two and three weeks.

(To be continued.)

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, October 14th, 1899.

PNEUMOCOCCAL SEPSIS WITHOUT PNEUMONIA.

MANY cases have been recorded in literature where pneumonia has been present without pneumococci being found. Pelnár, in Prof. Hlava's clinic, produces the antithesis in that the pneumococcus and its product were present without concomitant pneumonia; in proof whereof he gives the results of the post-mortem examinations. The first case was in December of last year, and on admission the patient had a high temperature, but died in a few days from eclampsia.

Post-mortem: purulent cerebral meningitis; partial atelectasis; enlarged spleen; follicular enteritis with thickening; calculi in right ureter; purulent rhinopharyngitis, herpes labii with general sepsis.

Microscopic preparations of the cerebral effusion yielded diplococci lanceolati, from the spleen diplococci of an atypical form were met with. Cultivations from the meninges and spleen yielded the typical diplococci of Fränkel-Weichselbaum. Sections of the brain and spleen, after hardening, revealed the same micro-organism.

The second case was that of a woman, æt. 22, in the puerperium suffering from scarlatina. The post-mortem gave somewhat similar results, purulent cerebral meningitis, laryngo-tracheo bronchitis, hyperæmia of the lung, enlarged spleen, parenchymatous degeneration of the liver and spleen, the uterus non-involved with residual shreds of placenta on its walls. General sepsis was originally diagnosed.

The placenta was normal as well as all the serous membranes, sections of the uterus and parametria gave negative results; and nothing abnormal could be discovered in the peritoneum.

Microscopic preparations of the tonsils yielded diplococci, both lanceolate and capsuled forms, the latter in chains. The same forms were found in the brain and splenic pulp. In the tracheal mucous membrane a few were found. Cultivations from the membranes of the brain, spleen, &c., yielded the diplococci of Fränkel-Weichselbaum, which formed chains best in glycerine

bouillon. When inoculated into dogs, the same diplococci were obtained from the œdema. In both of these cases clinically and experimentally no trace of pneumonia could be demonstrated. The probability is that the micro-organism gained admission to the body by infecting the mucous membrane of the mouth and nose (which is the usual channel for the diplococcus lanceolatus), and thence was carried to more remote organs, such as the brain and spleen, while the lungs escaped.

TETANUS AND BEHRING'S ANTITOXIN.

Dörner records a case of tetanus in which recovery was attributed to injections of Behring's antitoxin.

On January 19th a farmer had his hand injured by the bursting of a rifle. On the 21st he came to hospital with the injured hand wrapped up in wet cloths. No blackening from powder was observed, but a yellow viscid matter was everywhere present. The middle and terminal phalanges of the middle finger had been carried away, together with the soft parts of the fourth and fifth fingers as well as the index finger and thumb. After removing a number of the phalanges and dressing with antiseptic solutions all went well till March 3rd, when stiffness of the jaws was complained of. On the 5th spasms of the muscles appeared; on the 11th the spasms invaded the neck and shoulders; on the 15th the entire body was involved, with opisthotonos; pulse, 110; temperature, 37.4 degs. = 99.32 degs. Fahr. Uric acid was in the proportion of 1 to 26.28 of urea.

On March 16th he had 66 attacks of the spasms in twenty-four hours, 14 of which were very severe, notwithstanding the administration of six grammes of chloral hydrate. On the 17th he had 89 attacks, 33 of which were very severe. On the 18th, at mid-day, 25 grammes (each representing 250 units) of Behring's tetanus antitoxin were injected. The attacks numbered 202, temperature, 37.9 degs. On the following day another 25 grammes were injected and the dose of chloral hydrate repeated, and there were only 44 attacks. On the 20th, temperature, 36.9 degs., attacks, 50: two hours at a time quite free; no sleep, but the mouth could be opened; no stiffness in neck, and the proportion of uric acid fell to 1 as against 61.74 urea. On the 25th there were only two attacks in the twenty-four hours, and these were but slight. The following night he slept from twelve to eight o'clock; during the day a few faints. On the 28th he was able to open the mouth freely. On the 30th the chloral was stopped. On April 27th all the muscular groups were normal. The wound on the middle finger had a small granulating surface, while the others had cicatrised. On May 1st he was dismissed.

From the very first appearance of tetanus to the time of dismissal repeated microscopic examinations were made of blood, discharges, &c., but the tetanus bacillus of Nikolaier could not be found. Experiments on animals as well as anaërobic cultures were also negative. It should also be noted that the incubation period in this case was six weeks, with consequently a favourable prognosis. Richter's recoveries were 45 per cent. for fifteen days' incubation; Poland had 50 per cent. after twenty days.

AMONG the many congresses which are to meet in Paris during the Exhibition year is the second International Congress on Hypnotism. Nine subjects which seem to exhaust the whole subjects connected with hypnotism and its applications, are proposed for discussion.

Lunacy Department.

TENTH ANNUAL REPORT OF THE ASYLUMS OF THE COUNTY OF LONDON.

THE progressive increase of pauper lunacy in London still continues to attract considerable attention, and is relatively in excess of the increase of the population. The actual increase for which accommodation has to be provided by the county is 639. A graphic statement is furnished which shows the relation of the increase of London pauper lunacy to the increase of the population during the ten years, 1889 to 1898. The ratio per thousand of all pauper lunatics chargeable to unions and parishes in the county of London to the estimated population on January 1st, 1899, was as follows:—Mean ratio, 4.7; parish of Hampstead being lowest with a ratio of 1.9, and the Strand Union highest with a ratio of 10.1. The inference is that lunacy is increasing at a faster rate than the population. We have frequently pointed out that while technically this is so, it is an exaggeration to say that lunacy is actually increasing. The fact is, that many broken-down creatures are sent to asylums who would not be regarded as insane under the old conception of lunacy. They are incapable mentally, often because they are incapable physically, and they are real cases for the workhouse rather than the asylum, in a large proportion. Every care is exercised to limit the admissions to the asylums as much as possible, and many certified lunatics have to be detained for a considerable time in the workhouse infirmaries, and they have sometimes been certified several times because of the scarcity of proper accommodation. It is worthy of note that some of these cases have sufficiently recovered to enable them to be discharged without necessitating their removal to an asylum. It is, and has been for some years, recognised, that additional accommodation must be made to meet an increase of about 600 patients per annum, and the delay which has occurred in keeping up to these requirements has meant considerable additional cost for accommodation elsewhere. The medical statistics as regards recoveries and deaths for all the asylums are: recoveries on total admissions, 30.49 per cent.; on the total number under treatment, 6.70 per cent.; deaths on the total number under treatment, 7.15 per cent. Dr. Claye Shaw, in his report to the sub-committee of the Banstead Asylum, says, "It is worth noting that whilst the tendency of medical opinion is to treat private cases of insanity in uncertified houses, or to place them in the houses of medical men without certification, there seems to be an increasing desire to rush pauper patients into asylums. Many of the patients sent here might just as well be treated in infirmaries or hospitals, but there seems to be no great object on the score of economy for so dealing with them, inasmuch as pauper asylums are very, economically worked, whilst the fuss that is made if by chance an untoward event occurs to a person mentally affected, and treated in any other place than an asylum, makes responsible persons send the patients to an asylum whenever a vacancy can be got and the probability is that the larger the amount of available accommodation, the greater will be the number of candidates for admission, in other words, the amount of 'official,' i.e., registered lunacy increases with the accommodation provided. It

is difficult to see how this can be prevented by any other means than by some direct supervision over the cases proposed to be sent to the asylums. There appears to be no doubt that parish authorities show an increased readiness to demand asylum accommodation, and that the persons sent are often unnecessarily certified." At Hanwell there seems to have been some trouble with typhoid and erysipelas. Dr. Alexander, speaking of the latter says:—"The current opinion among medical men, that this disease is the result of overcrowding does not receive much support from our experience of it in 1898, for the cubic space in that part of the asylum is according to the authorised standard."

REPORT OF THE PATHOLOGIST.

Dr. Mott's report is as usual very interesting and valuable. He tells us that the signs of syphilis and the history of it is proportionally very much greater in general paralysis than in other forms of insanity, excluding brain syphilis. Atheroma of the aorta was found to be extremely common, but the severe forms were met with in general paralysis. Of ninety-one females who have died at Claybury forty-one had ulceration of the intestines, six of these were tuberculous, one was typhoid, and thirty-four were dysenteric. From the statistics of the weight of different hemispheres of the brain in persons dying insane he finds a marked contrast between the weights of the hemispheres in the general paralytic brains, as compared with other forms of insanity, and with the normal brain, in which the two halves balance each other. One of the most constant and the earliest symptoms of general paralysis is the affection of verbal and written language which progresses steadily with the dementia and paresis. He attributes the marked loss of weight of the left hemisphere as compared with the right in about 70 per cent. of the cases of general paralysis to the fact that we use the left hemisphere much more than the right; in consequence it is more liable to undergo degeneration earlier than the right. The corollary is that stress is an important factor in causing degeneration, and that structures which are used most are, if previously subjected to the devitalising influences of toxic agencies, such as syphilis and alcohol, the most prone to undergo premature decay.

The Operating Theatres.

GUY'S HOSPITAL.

BONE GRAFTING.—MR. ARBUTHNOT LANE operated on a child, æt. about 12, who had suffered from necrosis of the tibia, the bone having been removed at the epiphysal lines. This had occurred some years previous, and very little lengthening of the leg had taken place since, so that the right leg was much shorter than the left. The fibula had accommodated itself to the shortening, and was quite straight. She was unable to sustain her weight at all upon the shortened limb. He determined to make an effort to replace the shaft of the tibia by means of a graft, but found that the interval between the tibial fragments was too great to permit of its being filled up by any single bone, so he determined to do the operation in two stages. He therefore introduced the femur

of a very large rabbit into the interval, securing it as firmly as he could by wire to the upper fragment. An interval of about three-quarters of an inch remained between the lower end of the rabbit's femur and the lower tibial fragment. The absence of soft parts rendered it impossible to introduce another portion of rabbit's bone into the interval without endangering the safety of the larger graft. The limb was put up in plaster after this operation, any subsequent interference being postponed for at least six months. In performing the operation every precaution was taken to keep the wound and the graft sterile, the extremity of the rabbit's femur being trimmed to accommodate it to parts about, and the medulla was cleared of its contents. The chief difficulty experienced in the operation was due to the tension of the soft parts and skin, which resulted from the absence of the tibial shaft, they resting on and covering the inner surface of the fibula. The conditions presented by the tibial fragments in the child were small spikes of bone which extended upwards and downwards from the epiphyses, these were buried in the soft parts; the upper one was exposed and cleared and was perforated for the wire loops which connected it to the graft. When this had been done the rabbit was killed and its femur removed and prepared for insertion as already described. Mr. Lane pointed out that the mechanical conditions presented by this case were such as only offered to the surgeon the possibility of restoring to the child the capacity of transmitting through an already much shortened limb the superjacent weight of the body; he hoped, however that the child would be very materially benefited by the operation of introducing a rabbit's bone, which he had found of the greatest service in previous cases (reports of these have already appeared in the Operating Theatres). He said that in six months he proposed to expose the lower tibial fragment, and to connect it by a rabbit's bone to the graft just introduced. He hoped that as the result of the first operations the soft parts in the vicinity would become looser, and offer less resistance to the introduction of more bone. The wound healed in a most satisfactory manner.

Vital Statistics.

THE deaths registered last week in thirty-six great towns of England and Wales corresponded to an annual rate of 18·8 per 1,000 of their aggregate population, which is estimated at 12,786,832 persons in the middle of this year:—

Birkenhead 18, Birmingham 20, Blackburn 19, Bolton 15, Bradford 16, Brighton 15, Bristol 14, Burnley 16, Cardiff 16, Croydon 16, Derby 16, Dublin 29, Edinburgh 18, Glasgow 17, Gateshead 17, Halifax 13, Huddersfield 12, Hull 19, Leeds 19, Leicester 17, Liverpool 24, London 17, Manchester 24, Newcastle-on-Tyne 24, Norwich 14, Nottingham 17, Oldham 13, Plymouth 17, Portsmouth 16, Preston 22, Salford 25, Sheffield 22, Sunderland 23, Swansea 12, West Ham 15, Wolverhampton 20. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From measles 1·1 in Nottingham; from fever, 1·2 in Sheffield, and 1·6 in Bolton; and from diarrhoea, 2·9 in Wolverhampton and 5·8 in Preston. In none of the large towns did the death-rate from scarlet fever or from whooping-cough reach 1·0 per 1,000. The 117 deaths from diphtheria included 55 in London, 10 in Leeds, 10 in Sheffield, 9 in Leicester, 7 in Birmingham, 4 in Glasgow, 4 in Brighton, and 3 in Portsmouth. No death from small-pox was registered in any part of the United Kingdom.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR A SERIES OF INSERTIONS:—Whole Page, thirteen insertions (weekly, fortnightly, or monthly), at £3 10s. 6d.: twenty-six insertions (weekly or fortnightly) at £3 3s. 0d.: fifty-two insertions (weekly) at £3 each. Half Page, thirteen insertions at 35s.: twenty-six at 32s.: fifty-two insertions at 30s. each. Quarter-page, thirteen insertions at 18s.: twenty-six insertions at 16s.: fifty-two insertions at 15s. each. One-eighth page, thirteen insertions at 9s.: twenty-six insertions at 8s.: fifty-two insertions at 7s. 6d.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d.: Half Page £3 10s. 0d.: Quarter Page, £1 5s.: One-eighth, 12s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books &c.—Seven lines or under, 4s. per insertion; 6d. per line beyond.

Letters in this Department should be addressed to the Publishers.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 18, 1899.

NEW LIGHTS ON THE PLAGUE AT OPORTO.

WHEN the plague broke out at Alexandria, its occurrence sooner or later in European ports became a matter almost of certainty. It was our fortune to be able to announce the almost certain invasion of Oporto towards the end of July, several weeks before the discovery was made by the lay newspapers. The attitude of English journalism, both medical and otherwise, as regards this serious European invasion, is not a little curious and interesting. There can be no doubt whatever that the only accurate and trustworthy reports that have yet been made of the plague in Oporto have come from the Special Correspondent of the *Times*. His description of the facts of the case as regards, not only the extent and progress of the disease but also the conditions of racial and physical environment are worthy of the best traditions of the Local Government Board reports—that is to say, it is the work of a skilled observer who is versed in the principles of modern preventive medicine and is able to couch his tale in clear and vigorous English. As a result, after reading his special article, one has a clear view of the natural filth, sloth and ignorance, the official corruption, the bad sanitation, the foolish attempts at isolation and disinfection, and the farce of cordons and quarantine that together make the outlook for the future of plague in Oporto of a nature that may fairly be styled dubious and alarming. As a contrast with the energy and outlay of capital by means of which the *Times* has secured sound first-hand information let us turn for a moment to some of the statements with regard to the outbreak at Oporto that have appeared in representative medical journals at home. In its issue of October

7th the *Lancet* says that during the month of September there were seventeen cases of plague in that city, with four deaths. Now, if that were true, it would tend to persuade everyone that the disease had experienced a considerable check. What are the facts? We are in a position to state on authoritative and direct information that there were thirteen cases from the 1st to the 10th of September, while there were upwards of fifty cases in Oporto during the month of September. A similar inaccuracy of statement appears in the *British Medical Journal* for October 7th, which stereotypes the September return at seventeen cases and four deaths. The last mentioned journal, in its next issue on October 14th, stated that the plague bulletin for "last" week was the worst yet issued, and that twenty-eight cases of plague with three deaths had occurred during the week ending October 3rd. The number given, twenty-eight, agrees with our own figures, but there is the trifling error that the week should have been recorded as that ending on the 8th and not on the 3rd October. Inaccuracies of this kind are to be deplored when dealing with a subject of such current interest and importance as the invasion of Europe by the plague. Then there is another matter about which we feel it to be simply a matter of duty to speak out clearly and emphatically. A great deal has been said about Calmette's visit to Oporto and his persuading the Portuguese to be inoculated. As a matter of fact, he did nothing of the kind. During his fortnight's visit to the town he did not in any sense persuade the population to try protective vaccination, but it is true on the other hand that he induced a number of foreigners to adopt that measure and also a small proportion of native officials engaged in the hospital and sanitary services. The whole visit of Calmette appears to us to savour of of a commercial rather than of a scientific element. The report on his serum was said to have been signed by an International Committee at Oporto. If our information be correct, the document in question was franked by a certain number of signatures obtained haphazard from foreigners in the neighbourhood, and we believe we are correct in asserting that there is not a single German to be found among the list of signatories. What scientific conclusion could a fortnight's trial of this remedy be imagined to establish, and why should it require the support of an "international" document? Is not Calmette content to leave his plague serum to stand or fall on its own merits? But we claim a right to demand from M. Calmette the exact nature of his remedy, with which he proposes to replace Haffkine's serum, a preparation that may be regarded as being fairly, if not absolutely, established from a scientific point of view. Calmette's serum, we believe, is commonly described as the Yersin serum, that is to say, it has the synonym applied to Pasteur's serum. Now, the scientific evidence yet obtainable is all against the Yersin serum, and if M. Calmette has found it necessary to push the Yersin serum by such methods as those indicated, our readers will

agree that the sooner commerce and scientific medicine are divorced the better. Of course, it is possible M. Calmette may have adequate explanations and justification for his conduct of the Oporto serum mission. We trust that he will at least favour the world with a clear statement as to the identity, or otherwise, of his serum with that of Yersin. The bare suspicion that so terrible a scourge of mankind as the Oriental plague is being handled by way of commercial catspaw might well make the veriest cynic shudder, and we trust M. Calmette will at once take steps to clear the ground of anything that might, however remotely, suggest such a rock of offence. In future articles we shall hope to keep readers acquainted with the progress of the plague in Oporto.

THE NOTIFICATION OF MEASLES.

THE wisdom of providing for the notification of infectious diseases is now generally recognised, and the example set by this country is being followed in many others in a more or less perfunctory way. There may be differences of opinion as to the proper person or persons upon whom the duty of conveying the information to the authorities ought to be imposed, but as to the principle itself no such divergence of opinion can well exist. This being so, is it not somewhat inconsistent that measles should not be included in the schedule of notifiable diseases? This disease has a higher death-rate than any other zymotic disease except perhaps diarrhoea and whooping cough, yet practically nothing is done to check its ravages. The opposition which the proposal to notify measles has hitherto encountered has, in the main, been based on too narrow a view of the value of the system. It has been assumed that it is idle to notify a disease unless steps be taken to provide accommodation in isolation hospitals for the victims. This is a fundamental error, because compulsory sequestration is the *ultima thule*, and not the primary object of notification. As matters stand at present by no means every case of notifiable infectious disease is removed to the hospital, and in measles it is not indeed absolutely necessary. In the first place, an intimation of the existence of measles in a family would afford the medical officer of health an opportunity of educating the people on the importance of isolation and the propriety of removing the other youthful members of the family. Then, too, the knowledge would enable rigorous measures to be taken to prevent the conveyance of infection from home to the school, and to other aggregations of the young. At present no concerted measures of the kind are possible, and the public are left in the lazy belief that measles is a disease which every child must have almost of necessity, and which consequently calls for no special precautions. The very fact that it is excluded from the list of notifiable infectious diseases tends to reinforce this view for it may logically be argued that if the sanitary authorities treat it as a negligible quantity it cannot possess much importance. The only way to prevent an outbreak developing into an epidemic is to have early intimation of the first cases, and to

enforce the usual precautions. No one pretends that notification is likely to stamp out the disease, but if we can only lengthen the period of time which elapses between the widespread epidemics which now devastate whole districts at frequent intervals, and if we can in some part ensure that each outbreak shall burn itself out in its own particular locality something will have been accomplished in the direction of lessening the present high rate of mortality from this source. Of course even these moderate measures of repression cannot be adopted without some increase in expense, but the cost of prevention is necessarily vastly less than that of treatment, and it might be minimised, as suggested by Dr. Berry, the energetic Medical Officer of Health for Wigan, by limiting notification to the first case in a given household. This is an economical idea which might advantageously be extended to other diseases than measles. The important detail from an administrative point of view is the knowledge of the existence of infectious disease in a given locality. The occurrence of subsequent cases is information of second-rate importance, which could easily be obtained by the sanitary inspector in the ordinary course of his duties. No better definition of notification could be given than that with which Dr. Berry wound up his recent address before the conference of medical officers of health. "Notification," he observed, "is to sanitary officials what intelligence of the enemy's movements is to military officers." Without such knowledge, scientific warfare is an impossibility, especially the warfare against disease in which positions can, under no circumstances, be carried by assault.

SERUM THERAPEUTICS AND ANTITOXIN TREATMENT.

WE hear a good deal about the advances made in the domain of serum-therapy, but as a matter of fact the average practitioner must be at a loss to know exactly what this vaunted progress signifies. A glimpse of the actual state of the question was afforded by the necessarily brief discussion on the subject which took place at the first meeting of the Medical Society of London, though curiously enough, no one came forward with any observations bearing on the serum treatment of plague, a subject which is, however, very much the order of the day. For scientific purposes it is necessary to distinguish clearly between the different classes of serums, some of which, as antitoxins, act by neutralising or otherwise rendering inert the toxins secreted by the specific organism, while others act by inhibiting the development of the living microbe. Speaking generally, the latter are more useful for the purpose of affording protection, that is to say, prior to infection, while the antitoxins, as in diphtheria, render signal service, even after the disease has declared itself. There are, clinically speaking, two great classes of serums, the antitoxin or curative class, and the anti-bacterial or the protective class, though there are some which appear to possess, to a greater or less extent, both qualities. It

is hardly necessary at this time of day to insist on the unquestionable value of the diphtheria antitoxin, the efficacy whereof has been confirmed by statistics from all parts of the world. The cordial reception which this remedy has received at the hands of the medical profession everywhere must have a substantial basis of fact or we should have had a repetition of the criticisms which soon followed the introduction of Koch's first tuberculin, from which much was hoped, but which, in practice, soon belied the sanguine expectations which the name and authority of its inventor seemed to warrant. Even tuberculin, however, has its partisans, and Dr. Heron spoke in very favourable terms of the results which he has obtained with the new tuberculin. It must, however, be laid down as a primary condition, that the disease must be strictly localised to a small part of the lung, and must not be complicated by infection with other microbes. All cases in which the temperature exceeds 100 degs. F. at most, must be regarded as cases of mixed infection in which tuberculin can do no good. Curiously enough it does not appear to have occurred to anyone to try and stem the current of infection by a combined treatment of tuberculin and anti-streptococcic serum. This may be due to the fact that the therapeutical results of anti-streptococcic serum are somewhat dubious. It seems to exert a marked effect in certain cases and none whatever in others, and this failure to relieve drives us to the conclusion that there must be several varieties of streptococcus, all of which are not amenable to the same remedy. As there are at present no means of distinguishing the remediable cases from the others we must await more complete bacteriological knowledge of the natural history of this group of microbes. Another problem which awaits solution is that of preparing an antitoxin which shall be powerful enough to neutralise the toxin of diphtheria completely. At present it would seem that nervous tissue has such a marked affinity for the toxin that it can wrest it from the antitoxin in some cases, that at least is the explanation suggested by Dr. Washbourn, on Ehrlich's lines, of the fact that antitoxin does not save life in all cases. Probably, however, we have once again to do with mixed infections, and at this seems to be the rule rather than the exception, it behoves bacteriologists to devote themselves to the preparations of grapeshot antitoxins for use in our therapeutical artillery. Of the anti-pneumococcic serum Dr. Washbourn, though he was the first to prepare it on anything like a large scale, cannot speak in definite terms of approbation, but there seems to be no reason why it should not be tried on a more extensive scale in this country than has hitherto been the case. An altogether novel departure in serum-therapy has been inaugurated by Dr. Hubbard who makes use of the serums, not in view of their antitoxic or anti-bacterial properties, but as coagulating agents. He claims to have obtained tangible relief in certain cases of aneurysm of the aorta, and to have arrested the hæmorrhage in menorrhagia and

in hæmophilia. If these results are confirmed by other observers there is reason to hope that an agent of considerable power has been added to the resources at our disposal in dealing with hæmorrhagic conditions. Hæmophilia, indeed, is a condition which one might have thought would long since have tempted the serum-therapist, seeing that, theoretically, it ought to be possible to supply artificially the coagulating agent which is wanting. Instances of death from hæmorrhage in the subjects of this abnormality, though not of everyday occurrence, are still sufficiently numerous to make it worth while to study its prevention, but in view of what precedes it may be that the task has already been accomplished by Dr. Hubbard.

Notes on Current Topics.

Vapours.

THERE seems to be a tendency now to study somewhat carefully the influence of the atmosphere in a certain class of maladies of the respiratory organs, which are difficult to treat by remedies administered through the stomach. The last edition of the British Pharmacopœia excludes the six vapours which were contained in former editions, for the good reason probably that they were of no practical use. There is no doubt but that the health of a people depends largely on the air they breathe, and certainly the subject is one of great interest to those who appear to inherit tendencies of serious character, which are likely to assume under certain circumstances a fatal form. The question of the causes which influence the atmosphere is beginning to be inquired into. The nature of the soil certainly has a great influence. The difference between clay, sand, and chalk is fully appreciated by those who live in London or its suburbs; and if we go further afield we cannot but notice very great differences in the various parts of our coast as well as in the interior of our island. The pathological aspects of geology might well in some form or another constitute part of the education of those entering the profession, for without this they cannot understand why the climate in various parts differs as it does. If now there are good reasons for resorting to inhalations in the treatment of lung diseases, we have to consider the qualities of vapours and the agents we employ. The subject has not been studied as it deserves, and there is yet a great deal to be learned, before we can decide upon the best methods to be employed for utilising many agents, when we endeavour to administer them not as solids or liquids, but in the form of vapours. When we see what use has been made of chloroform, ether, or nitrous oxide gas, it is suggested that various volatile substances, such as phenol, menthol, the turpentine, benzoic acid, camphor, and others might prove of great value when we change them from the solid or liquid form into that of vapour. We hope that it will not be long before we have more accurate knowledge on

this matter than was evidently possessed by those who introduced the vapours into the British Pharmacopœia, or even by those who struck them out.

The Plague in England.

WHILE the general newspapers contain sheets of war news they can spare no more than an obscure paragraph to announce the fact that a case of plague has been brought into Plymouth. Yet not so long ago that announcement might have heralded in an invasion more terrible and costly both in life and in treasure than that of any human foe. The facts are that on the 14th instant the P. and O. Company's steamer *Peninsula* arrived at Plymouth from Bombay. The day after leaving Marseilles, on the 9th instant, a Leedi boy, employed as a coal trimmer, was taken ill with the plague. As the incubation stage of plague is not more than five days it will be interesting to learn whence the Leedi boy brought the infection. Possibly this case is the first intimation of the invasion of France. In our own country, with its fairly good general standard of port and inland sanitation, and its rational system of supervisory quarantine, we need have no fear that this scourge will find any real foothold upon our shores. It is interesting to compare the present attitude of dilettante interest and curiosity in the advent of the plague with the panic it would have caused even a generation ago.

Hospitals and Rates.

GROWTH appears to be a necessary complement of health, and though this may not hold good of animal organisms at all periods of their healthy existence it certainly seems to apply to public institutions. In accordance with this impulse of expansive vitality the Sheffield Royal Infirmary is preparing to stretch its limbs, swathed in brickwork, but to do this with ease the bagatelle of £30,000 is required, and the means of raising this sum was discussed last week at the annual meeting of the governors. The Lord Mayor of Sheffield, in the course of his remarks, held out the hope that if proper application were made to the City Council it might be possible to induce that body to forego the payment of rates from such a deserving institution. Inasmuch as the amount at present paid exceeds £200 per annum, and after the proposed extension may reach £500, the suggestion is one of considerable importance. It is hardly necessary to add that before the meeting came to an end a resolution was passed inviting the attention of the City Council to this subject. This conduct offers a somewhat invidious contrast with that of the rating authorities of London towards the magnificent institutions which minister to the medical wants of the metropolis. In times gone by exception might reasonably have been taken to exemption from rates on the ground that it would be unfair to tax the inhabitants of particular parishes for the maintenance of several hospitals, the benefits whereof were not by any means limited to the district, but with an Equalisation of Rates Act this

objection ceases to have any bearing. Why a place of worship should be exempted while a hospital is taxed it is not easy to understand, but for the matter of that this is only one of many things in the social edifice which defy explanation.

Medical Appointments for the War.

THE following were gazetted on Friday last:— Surgeon-General W. D. Wilson, M.B., to be Principal Medical Officer. Major W. G. A. Bedford, M.B., Royal Army Medical Corps, and Captain M. L. Hughes, Royal Army Medical Corps, to be Medical Officers on the staff. Colonel E. Townsend, M.D., C.B., Royal Army Medical Corps, to be Principal Medical Officer, and Major C. H. Burtchaell, M.B., Royal Army Medical Corps, to be Medical Officer of the First Division. Colonel T. J. Gallwey, M.D., C.B., Royal Army Medical Corps, to be Principal Medical Officer, and Major W. Babbie, M.B., C.M.G., Royal Army Medical Corps, to be Medical Officer of the Second Division. Lieutenant-Colonel J. D. Edge, M.D., Royal Army Medical Corps, to be Principal Medical Officer, and Major G. E. Twiss, Royal Army Medical Corps, to be Medical Officer of the Third Division. Lieutenant-Colonel W. Donovan, Royal Army Medical Corps, to be Principal Medical Officer, and Major H. G. Hathaway, Royal Army Medical Corps, to be Medical Officer to the Cavalry Corps. A draft of the Royal Army Medical Corps left Portsmouth on Monday for Southampton, where they went aboard the hospital ship *Trojan*, for duty. Most of the nursing sisters and doctors in the Corps have been warned to hold themselves in readiness for South Africa.

Food Poisonings.

IF the frequency of cases of food poisoning were to be depended upon as an index it would hardly be possible to escape the conclusion that such occurrences were vastly on the increase. Beyond the introduction of tinned meats within the memory of the present generation, however, there has been no marked alteration in the food of the people. After all the percentage of poisoning cases from tinned food must be small. What really happens is that general attention has been drawn to the subject of ptomaine poisoning. There is hardly a general newspaper writer in the length and breadth of the country who has not something to say about the matter. The consequence is that if a family (say in the North of Scotland) eats cold veal pie on Sunday, and gets purging and vomiting during the night the fact is reported in the London evening papers on the Monday. In other words the number of cases is not so much increased as the quickness and certainty with which they are recounted in general journalism. By the way, it is somewhat curious that although the matter has been before the world of scientific medicine for more than a few years yet little is really known about the matter. Ptomaine poisoning is an acute and well-defined symptomatic malady, yet

we are curiously at fault as to the recognition of the toxic matter, either in the tainted food or in the patient's corpus. The only practical lesson of any value yet gathered appears to be to enforce the need of absolute wholesomeness in all that we eat or drink.

Succour to the Sick and Wounded in the War.

THE outbreak of war with the South African Republic has again afforded the philanthropic British public the opportunity of doing something to relieve the sufferings of the sons of the Empire who will be engaged in fighting their country's battles. During the Franco-German war a British Red Cross fund was started which resulted in subscriptions amounting to £500,000 being collected for the sick and suffering in that great contest. From time to time the surplus which remained has been drawn upon and employed in our recent wars in Egypt and the Soudan, but the sum still unspent is regarded as insufficient for the needs of the war which has just broken out in South Africa. Accordingly, in the name of the Central British Red Cross Committee, Lord Wantage makes an earnest appeal for contributions in order to enable the societies which he represents to carry on their excellent humane work among the British troops. It is proposed to provide in South Africa two hospital railway trains for the transport of the sick and wounded, and to fully equip a hospital ship, thus supplementing the transports now being prepared by the War Office for the conveyance of the sick and wounded from Natal to the Cape and home. Thus it is evident that the scheme of succour now being organised by the Red Cross Committee is destined to prove of immense service in the cause of humanity, and we, therefore, do not doubt that the public will see that ample funds will be forthcoming for the purpose.

Professional Etiquette from a Legal Aspect.

WHAT is known as "professional etiquette" in the medical profession has often been made the subject of unfriendly criticism by laymen. Indeed, the latter have frequently expressed themselves to the effect that they cannot understand why medical men should be bound by the unwritten laws of ethical procedure. Of course, the profession cannot be responsible for supplying the intelligence necessary to the understanding of these or any other matters with which laymen may be concerned. Nevertheless, mention may be made of the fact that if there were no such thing as professional etiquette, regulating the intercourse between medical men, the public would very soon find that all sorts of difficulties and unpleasantnesses would occur between their medical men and themselves. Bearing, then, these facts in mind, we trust that the result of a trial which took place last week in the Market Drayton County Court will not be lost upon the cavilling section of the public who profess to see in professional etiquette nothing but nonsense. The facts of the case are as follows. A medical man named Dr. Yates, sued a cheese factor for half a

guinea fee on behalf of an employee of the latter, to whom he had been summoned. The practitioner responded at once to the call, and travelled a distance of six miles for the purpose. On arriving at the house, however, he found that the patient had already been seen by a *confrere*, and that the accident, a fractured leg, had occurred about three days previously. Dr. Yates having ascertained these facts, refused to see the patient professionally, and returned home. However, a fee of half-a-guinea was charged for the abortive visit, which the cheese factor declined to pay. The defence was advanced that the practitioner had not fulfilled his contract by undertaking the treatment of the case. But the judge held that Dr. Yates could not have done other than he did on finding that another practitioner was in attendance. He further added, significantly, that professional etiquette was part and parcel of a doctor's profession, and ultimately gave judgment for the plaintiff with costs. The decision is really an important one, for it establishes the fact that professional etiquette possesses a legal value.

Medicine in Decadent Nations.

IN an interesting article by M. Gaston Deschamps on "La Fin d'un Monde," there is an interesting passage which touches on a phase of medical history which savours of original observation. When, he says, nations are declining, man, no longer having the consciousness of a great task to be accomplished and no longer being sustained by an ideal, readily falls into the habit of regarding death as a thing to be dreaded and develops an exaggerated regard for his perishable body. The citizens of the Asiatic cities, he observes, thought more about their health than anything else. They had, so to speak, "the religion of their skins." A noteworthy phenomenon, one which invariably presents itself among decadent peoples, is the apotheosis of the physician. The degenerate Greeks could not well escape the application of this general law. If we read the honorific registers of the Asiatic province we see numerous examples of the fulsome praise of physicians such as might have fallen from the pen of a frightened sufferer. Menophile, son of Dosithea, a physician of Cadyanda, received as a recompense for his services a golden crown and his bust in bronze. Elsewhere a certain Heraclitus, who rejoiced in a purely local fame, is proclaimed to be "the foremost physician of the century" and "the Homer of Medicine."

The Malarial Mosquito.

THE return from the Gold Coast of the Malarial Expedition organised by the Liverpool School of Tropical Diseases was warmly heralded by the press throughout the country last week, and there is no doubt the welcome extended to the Commission was thoroughly deserved. In less than three months they have accomplished much in a scientific sense. Major Ross, I.M.S., has now placed beyond a question the direct relation between malarial fever and a certain species of mosquito. His object in taking part in the expedition was to ascertain the

special insect concerned in the transmission of the disease, and this he has attained with a success which can only be regarded as most gratifying. Dr. Fielding Ould, of Liverpool, who was recently sent out, and joined the expedition at Sierra Leone, has been left there in order to continue the duty of instructing the medical men in the district concerning the mosquito and the method of exterminating the dangerous species. It is needless to add that the members in the profession upon the Gold Coast have shown a keen interest in the important investigations which the expedition have brought to such a successful close. Major Ross has asserted that in his opinion it would be an easy matter to exterminate the mosquito responsible for the dissemination of the malarial micro-organism, and that the work could be carried out at a trifling expense, so far as the principal towns are concerned. But whatever the cost may be, every effort should be made in the localities concerned to give effect to the measures of prevention which Major Ross has shown to be necessary. Moreover, now that the cause of the dissemination of malarial disease has been proved, the Government should take the matter in hand, and encourage the carrying out of Major Ross's instructions in all other parts of Greater Britain where malaria prevails.

The Royal Army Medical Corps on its Trial.

THE address descriptive of the shortcomings of the Royal Army Medical Corps, given by Professor Ogston at the Portsmouth meeting of the British Medical Association, has now been endowed with an additional interest, for it is certain that with the outbreak of war the opportunity has now come of showing whether Dr. Ogston was justified or not in his criticisms. The *Journal* of the American Medical Association, when discussing this subject a week or two ago, said:—"The English people, while comparatively pachydermatous as regards criticism from without, do not take kindly to public acknowledgments of their faults from home sources, even in a modified and comparatively harmless way. Dr. Ogston's recent address on the faults of the British Army and Navy Medical Services has therefore stirred up something of a wasp's nest sort of turmoil. . . . We wonder what the British public would have to say to such rampant criticism of all kinds as everything in our late unpleasantness with Spain received from responsible and irresponsible writers last year. It would be a new experience to them, but we can dismiss it from our imaginations as an impossibility in any country but our own." The war in South Africa, however, has now placed the medical service of the army on its trial, and we doubt not that keen interest will be generally taken in the manner with which the Department acquits itself of its duties. We have persistently contended that if faults are to be found with its equipment and organisation these cannot be attributed to the medical officers. The stumbling block in the way of much needed reforms is the War Office. "My

military advisers," instead of affording encouragement to the officers of the Royal Medical Corps to bring their department up to date are apparently jealous of the efforts of the latter to improve the service. But we shall see what this war brings forth in the test to which the Army Medical Service is about to submit. We are not too hopeful of its being able to establish its efficiency; nevertheless, we earnestly trust that no breakdown will occur, or any untoward *contretemps*, to prove the truth of the misgivings to which currency was given by Dr. Ogston in his address.

The Bacteriology of Plague.

THE facts connected with the life, history, and methods of detection and destruction of the plague bacillus have an unusual interest at the present moment, when this disease is within two or three days' voyage of our own shores. The small specific black rod, somewhat shorter than the typhoid organism, was discovered independently by Kitasato and Yersin during the Hong Kong epidemic in 1894. They possess flagella which stain with difficulty, and a central portion of the bacillus often remains uncoloured, forming the so-called "pole-staining." In cultures, the bacilli often run into chains of "strepto-bacilli." On dry agar, with a slightly alkaline reaction, involution forms are rapidly found at body temperature, while another characteristic of growth is seen in powdery "stalactite" flakes seen on the surface of bouillon cultures when kept at rest. Rats, mice, guinea pigs, rabbits, monkeys, and other animals are susceptible to inoculation, and are supposed in some instances to convey the infection. Yersin, Calmette, and Borrel injected cultures killed by heat into rabbits, and procured a certain amount of immunity. They also obtained a serum from a horse immunised by intravenous injection of living bacilli, but this serum has not established its scientific reputation in India. Haffkine's method, on the other hand, is a bouillon culture killed by an exposure to 70 degs. C. for one hour. Preventive inoculation by Haffkine's plan has been systematically and extensively tested in India with results that are most encouraging and full of promise, although they still fall short of complete scientific demonstration.

Mr. Chamberlain and Tropical Diseases.

MR. CHAMBERLAIN has now the opportunity, with the return of the Liverpool School of Tropical Diseases Malarial Expedition, of doing something to show the official appreciation of the work which has been accomplished. We refer to this matter in another column. Up to the present the Colonial Secretary has practically done nothing for the Liverpool School, which has so justly proved itself deserving of support. But where official assistance has been withheld local enterprise has been abundantly shown, as the result of which it can be said that the Liverpool School of Tropical Diseases is bound to take a leading position.

A Russian University for Women.

It has apparently fallen upon Russia to lead the way in founding a university for women. A wealthy Russian died recently and left the magnificent sum of £100,000 towards the foundation of a university for women in Moscow, to comprise a mathematical, scientific, and medical faculty. The Municipal Council of Moscow, inspired no doubt by this generosity, have agreed to supplement it by an annual grant of £300. Thus the land of the Czar may be backward in granting emancipation to the serfs, but from the above announcement one may conclude that no objection is raised to the emancipation of women. That there is no woman's university in this country is somewhat a blot upon our national character. The increased freedom which, owing to the advancement of the times, and the bursting of many bubbles of antiquated customs, is now being enjoyed by British women, has not been abused, nor can it be said that the nation has failed to benefit from the change. As, therefore, women have eminently proved themselves worthily capable of profiting by a greater freedom, facilities should be afforded them of developing their mental and physical resources. A woman's university must certainly be regarded as a desideratum in this country, in view of the difficulties placed in the way of the academic advancement of the sex.

Vaccination Law in Japan.

THE Japanese have repeatedly shown their wisdom by their adoption of Western civilised customs. The Government of the country have now decreed that vaccination shall be compulsory throughout Japan, and that all children shall be vaccinated before reaching the age of ten months, also that re-vaccination shall take place when they are six and twelve years of age respectively. It will be interesting to note the effects of this in after years, and to compare the results of its operation with those now obtainable. We wonder if any anti-vaccination societies will be started in Japan with a view to opposing the law. Possibly not, for although Japan is in many respects a highly-civilised nation, it probably is still not advanced enough to allow "cranks," "faddists," and others to make fools of themselves and the public without summarily interfering with their programme. In this respect Japan has distinctly the advantage of us.

A Criminal's Brain.

SOME months since was executed in France a certain nomad who had committed a long series of execrable crimes, more particularly in violating and afterwards killing and mutilating young girls. Although he simulated madness, the medical experts refused to endorse that line of defence, and he duly expiated his crimes on the scaffold. His brain was deposited at the Musée Dupuytren, and has since been carefully examined, microscopically and otherwise, by several psychologists of experience, who hoped to find, or thought they might find, something in the cerebral conformation or intimate structure to

account for the subject's well-marked criminal propensities. Not without a vague regret we learn that the results of the investigation were altogether negative. No abnormality was discovered nor anything that could throw light upon the mental tendencies of the one-time owner of the brain. There is, of course, nothing surprising in this. The same absence of obvious abnormality has been observed in numerous instances of notorious madness, and when we reflect that, after all, morbid mental tendencies are the outcome of want of equilibrium between the functional areas and not of any essential vice of conformation it is evident that the discovery of a physical basis for criminal instincts is never likely to be achieved. Until, however, that shall have been accomplished it will be difficult to educate public opinion to the belief that crime, like inebriety, is a symptom of disease.

Atropine Poisoning Case at Kendal.

A CURIOUS case of poisoning occurred last week at Kendal. A family consisting of a man, his wife, and four children were taken seriously ill after dinner with symptoms of acute poisoning. The father and three of the children were removed to hospital, where the children have been detained for several days. Investigation showed the presence of atropine in a dish of beetroot of which the family had partaken at the dinner table. It was next ascertained that one of the children had been using an eye lotion obtained from the Liverpool Ophthalmic Hospital, and one of the ingredients of the application was atropine. How the contents of the physic bottle were mixed with the vinegar is unknown, but the accident seems to have been connected with a recent house removal. The comparative frequency of this accidental atropine poisoning by means of eye "drops" or lotions renders it desirable that every medical practitioner should be familiar with symptoms and with antidotes. Fortunately, the action of the drug is characteristic. The dry mouth, the dilated pupils, the disturbed vision, the excitement, the delirium, the dry skin, the muscular weakness, and the ineffectual desire to pass water form an unmistakable clinical picture. The treatment is to empty the stomach with mustard or other emetic and copious draughts of hot water, or by the subcutaneous injection of apomorphia. Half a grain of pilocarpine should then be given hypodermically (10 minims of the 1 in 20 solution). Two grains of atropine have proved fatal. The liquor atropinæ contains 1 grain in 101 minims.

Register! Register!

THE General Medical Council has issued, through our columns, its annual appeal to the members of the profession throughout the kingdom to supply, each for himself, the information necessary for a correct entry in the *Medical Register* of 1900. We should have supposed that having regard to the slight trouble which it costs, every medical man would take care to be accurately gazetted in the *Register*. Apart from the consideration that he may be tripped up in the giving of certain certificates if his entry is wrong,

it certainly cannot be to the advantage of any practitioner that magistrates and other persons who refer to the *Register* for official information should be led astray respecting the qualifications and residence of the practitioner. Newly-qualified men should, if possible, effect their registration in order that they may appear in due and correct form in the forthcoming *Register* for the first year of the new century.

Terms of Comparison.

WE have more than once animadverted on the vagueness and incongruity of the terms of comparison so commonly employed by physicians, surgeons, and pathologists, in attempting to give a picture estimate of size. There is the conventional millet seed, but it is open to question whether the botanical knowledge of the average reader enables him to identify this particular agricultural product. Though better known, the size of a filbert is equally uncertain, for its dimensions vary within fully as wide limits as the orange. We are all familiar with the tumour which is described as the size of the fist, but every pugnacious schoolboy is aware that there are fists and fists, some of comparatively little import from an offensive point of view, while others inspire respect if not awe. The foetal head is possibly less variable in size than some of the objects just referred to, but even then the observer ought at least to take the precaution to state whether he means the head of the foetus at term or at some earlier period of pregnancy. It would be much more scientific to give the dimensions in inches or centimetres using fruits and seeds foot-balls and foetal heads merely to indicate the approximate shape. It may be permissible to describe the terrestrial globe as having the shape of an orange, but it would be grotesque to explain that it was so many times larger than this fruit. For all practical purposes those who make use of these terms of comparison might as well say right out that the growth was "about the size of a lump of chalk."

Anæmia and Syphilis.

AT last Friday's meeting of the Clinical Society, a discussion arose on an obscure case of anæmia which had resisted all the usual methods of treatment, and incidentally an interesting fact was alluded to which embodies a useful hint to practitioners, viz., that in many cases of refractory anæmia the cause may be inherited syphilis. In all such cases, therefore, it behoves one to institute close inquiry into family and personal history with the object of eliciting the possibility of this etiological factor: indeed, when other remedies have failed, it would be well to try the effect of a mercurial or iodide treatment before classing and abandoning the case as one of pernicious anæmia. It was noted by one speaker that an excess of eosinophile cells had been noted in a case of this kind which proved post-mortem to have been syphilitic, such excess being absent in a very similar case, which post-mortem

presented only the lesions usually associated with pernicious anæmia.

The Pathological Society of London.

THE Pathological Society of London, desirous of moving with the times, have determined to strike out a new departure, and it is announced that in future four of the fifteen meetings will be held elsewhere than at the usual meeting place of the Society, 20, Hanover Square. The object of these four "Laboratory Meetings" is to enable experimental work to be demonstrated before the Society, on the lines laid down by the younger and highly successful sister Society, the Physiological, in that the proceedings will be less public, and it is hoped on this account more productive of frank discussion and exchange of opinion. It is felt that the publication of discussions sometimes tends to hamper criticism, and with the view of obviating this the Council of the Pathological Society have passed a resolution that at the Laboratory meetings the discussions shall be private and that the papers read shall only be published in abstract in the medical journals if the authors so desire. The object of this last clause is to enable men engaged in research to bring forward for discussion and criticism work as yet immature, and not ready for formal publication. In this way many communications of interest will be brought forward, and workers will gain much in the progress of their work from friendly and confidential criticisms of their audience. The first of the "Laboratory Meetings" will be held at the Jenner Institute on Tuesday, November 7th, at 8.30 p.m. After Christmas similar meetings will be held at University College, King's College, and the Laboratories of the Royal Colleges of Physicians and Surgeons. A special evening will also be set apart for the discussion of papers on pathological chemistry. In thus exerting itself to hear all sides of pathological work, and to include research work in the newer and rapidly developing subjects of bacteriology, experimental pathology, and pathological chemistry, the Society is to be congratulated, while it is of course intended that the Society should continue to be the means of making public advances in the important subjects of morbid anatomy and histology, for which it has done so much in the past.

Tetanus.

THE statement is published that M. Nocard has distributed a large quantity of anti-tetanic serum which has been used for injection into various animals as a prophylactic against tetanus. He asserts that out of 2,300 beasts so injected not one suffered lock-jaw after operation. So far, good, but we should like to be told how many of them would, probably, have so suffered if they had never been injected.

DR. W. J. COLLINS is to be presented with his portrait, painted by Mr. Hugh Herkomer, as a memento of his chairmanship of the London County Council in the Diamond Jubilee year.

DR. G. VIVIAN POORE will deliver the annual Harveian oration at the Royal College of Physicians, London, to-day (Wednesday), at 4 p.m.

MR. THOS. E. FLITCROFT, L.R.C.P. Edin., L.F.P.S. Glasg., of Parkhurst, Bolton, has been appointed a magistrate for that borough by the Chancellor of the Duchy of Lancaster, Lord James of Hereford.

SIR THOMAS GRAINGER STEWART, Physician to the Queen in Scotland, who has lately been residing at Dunbar on account of ill-health, has now returned to Edinburgh. He is in improved health, but has been advised not to deliver lectures in the University during the ensuing session.

It is perhaps not generally known that the late Right Rev. John Wale Hicks, Bishop of Bloemfontein, was a doctor of medicine of the University of London as well as doctor of divinity of the University of Cambridge. The deceased prelate had even carried off the gold medal in obstetric medicine, which must be a rare achievement in the annals of the bishops. He must have been just the man for a colonial post, and this assumption is more than borne out by the popularity he enjoyed while alive, and by the expressions of regret which his death has called forth.

Scotland.

[FROM OUR SPECIAL CORRESPONDENT.]

THE LATE DR. WILLIAM MENZIES HUTTON, F.R.C.S. ED.—Dr. Hutton, the surgical registrar to the Royal Edinburgh Infirmary, an appointment he succeeded to only last winter, succumbed last week to a tuberculous affection of the throat and lungs at the early age of 29. Gold medallist for his M.D. Thesis, Syme Surgical Fellow of the Edinburgh University in 1893, F.R.C.S. Ed. in 1895, his career promised well, and death has intervened all too soon. Dr. Hutton had been for some years past one of the most successful coaches in medical and surgical subjects in Edinburgh. He became ill not very long after appointment to the surgical registrarship at the Royal Infirmary, and since last spring was unable to undertake any of his duties.

A BATCH OF NEW PROFESSORS FOR GLASGOW.—The coming session will find the University of Glasgow with three new professors, viz., Dr. Andrew Gray, formerly assistant to Lord Kelvin, has been appointed to succeed his lordship in the chair of Natural Philosophy; Mr. Dudley Julius Medley, M.A., Oxon., has been appointed to fill the chair of English Literature, rendered vacant by the resignation of Professor Lodge, who has gone to Edinburgh; and Mr. Phillimore, who succeeds Professor Murray to the chair of Greek. Certainly the session will open with fresh blood, and the new professors are men who are certain to do justice both to the University and to themselves.

GLASGOW UNIVERSITY RECTORIAL ELECTION.—At present there is a great squabbling going on, both in print and orally between the two sections of students as to the most suitable candidate for the position of Lord Rector. One section is highly indignant that Lord Kelvin should be brought forward in opposition to Lord Rosebery, and suggests that the latter should be unanimously returned just now, with the understanding that Lord Kelvin be also unanimously returned when the time next arrives for the appointment of a new Lord Rector. The opposite side contends that Lord Kelvin being the older man, who for fifty-three years shed lustre on the university, a general favourite, one

who would not be merely an ornamental Lord Rector should be at the present time returned, and after his term of office has expired, Lord Rosebery should succeed to the position. We think the latter proposal a good one and feasible, but it will be difficult to decide where party feeling runs high. In any case, there will be a great deal of ink spilled and much jostling before the affair is finally settled.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—The following gentlemen have been appointed office-bearers for the ensuing session.—President—Mr. H. E. Clark. Section of Medicine—Vice-President, Dr. W. G. Dun. Councillor, Dr. J. W. Allan. Secretary, Dr. Jas. Hinshelwood. Section of Surgery—Vice-President, Dr. John Barlow. Councillors, Dr. Rutherford and Mr. Maylard. Secretary—Dr. J. H. Nicoll. Section of Pathology—Vice-President, Dr. Lindsay Steven. Councillors—Drs. Workman and Teacher. Secretary—Dr. R. M. Buchanan. Section of Obstetrics—Vice-President, Dr. John Edgar. Councillors—Drs. J. K. Kelly and Gibson. Secretary—Dr. Balfour Marshall. Treasurer—Dr. Barclay Ness. Editorial Secretary—Dr. W. E. Jack. General Secretary—Dr. W. K. Hunter.

Manchester.

[FROM OUR OWN CORRESPONDENT.]

WOMEN MEDICAL STUDENTS.—At last the authorities of Owens College have bowed to the inevitable. The charter of the Victoria University permits the admission of females as graduates in the faculty of medicine. Hitherto the leading college has, however, made no provision for their training. Now sex will be no bar, and before long it is hoped that adequate arrangements will be made for the thorough instruction of women in the clinical as well as the scientific work of a full medical curriculum in Manchester.

ST. MARY'S HOSPITAL.—The foundation stone of the new building of this old and much valued institution for the treatment of women and children was recently laid by the Countess of Derby. In spite of its anything but ideal site the building promises to be a thoroughly modern and suitable hospital. It is to accommodate 125 patients, the main portion being reserved for diseases of women and children, and with a separate department for maternity cases. Adequate arrangements are being made for the training of medical students, nurses, midwives, and monthly nurses.

DENTAL HOSPITAL.—The Manchester Dental School, a department of the Owens College, has its clinical centre at the Victoria Dental Hospital. The opening address was this year delivered by Professor Leech, who expressed the view that it might be possible to establish a degree in dentistry. Since the founding of the Dental Hospital aid has been given to over 160,000 patients.

PATHOLOGICAL SOCIETY.—This, the largest medical society in Manchester, numbering over 400 members, held its annual meeting on Wednesday last, when the following officers were elected for the ensuing session:—President—W. Thorburn, B.S. Vice-presidents—E. S. Reynolds, M.D., A. Brown, M.D. Treasurer—T. A. Helme, M.D. Secretary—T. N. Kelynack, M.D. Research Secretary—F. C. Moore, M.D. Committee—J. G. Clegg, M.D., W. F. Fothergill, M.D., J. E. Platt, M.S., A. W. W. Lea, M.D., F. C. Moore, M.D., W. A. Penshaw, E. J. Sidebotham, M.B., J. W. Smith, F.R.C.S. The following gentlemen were elected honorary members:—R. W. Boyce, M.B., Professor of Pathology, University College, Liverpool. H. B. Dixon, M.A., F.R.S., Professor of Chemistry, The Owens College, Manchester. S. J. Hickson, M.A., D.Sc., F.R.S., Professor of Zoology, The Owens College, Manchester. W. E. Hoyle, M.A., F.R.S.E., M.R.C.S., Keeper of the Manchester Museum, The Owens College, Manchester. W. H. Perkin, Ph.D., F.R.S., Professor of Organic Chemistry, The Owens College, Manchester. E. F. Trevelyan, M.D. B.Sc., Professor of Pathology, The Yorkshire College, Leeds. F. E. Weiss, B.Sc., Professor of Botany, The Owens College, Manchester.

CLINICAL SOCIETY OF MANCHESTER.—The following have been elected office-bearers for the session 1899-1900:—President—Judson Bury, M.D. Vice-Presidents—T. A. Helme, M.D., E. S. Reynolds, M.D. Hon. Treasurer—C. H. Braddon, M.D. Hon. Secretary—J. E. Platt, M.S. Hon. Librarian—J. W. Smith, M.B. Committee—Alfred Brown, M.D., J. G. Clegg, M.D., R. Crean, M.D., J. Daniel, M.D., J. W. Hamill, M.D., J. Holmes, M.D., C. F. H. Kitchen, M. P. Ledward, M.D., C. T. B. Maisey, R. T. Parkinson, M.D., T. Porter, M.B., J. Rust, Graham Steele, M.D., F. H. Westmacott, J. P. Williams, M.D.

THE PROGRESS OF RHINOLOGY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Ball, in his admirably concise and lucid address on "The Progress of Rhinology" (MEDICAL PRESS AND CIRCULAR, October 11th), has given so much credit to Englishmen that I am sure he will excuse me saying that another Englishman, Spencer Watson, preceded Ziem of Danzig by five years in drawing attention to the fact that in empyema of the maxillary antrum the classical signs of pain, heat, redness, and swelling laid down in all manuals of surgery up to, and long after that date, as diagnostic of the condition, are, in the majority of instances, conspicuously absent. Also that although during the seven or eight years ending 1873, that I was associated with Sir Morell Mackenzie, I never saw a case of empyema of any of the accessory cavities diagnosed, either in his private or hospital practice—a proof that such maladies were at that time practically unknown, but in February, 1879, fully a year preceding the publication of Ziem's observations, I was able to report three cases of maxillary empyema at the Harveian Society; they are recorded in the *British Medical Journal* of March 8th, 1879.

I am, Sir, yours truly,

LENNOX BROWNE.

Mansfield Street, W., October 14th, 1899.

CHLOROFORM v. ETHER.—ST. BARTHOLOMEW'S HOSPITAL REPORTS.—A CORRECTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the number for October 4th, 1899, p. 363, there is a review of the St. Bartholomew's Hospital Reports in which your reviewer has fallen into a slight error. He says: "During 1897 anaesthetics were administered 4,893 times, and it may interest those who, in season and out of season, advocate ether, to know that 201 cases of etherisation are recorded as against 1,959 chloroformisations. Ether, it thus appears was found suitable in no more than 4 per cent of the cases requiring an anaesthetic, whereas chloroform was used in almost 40 per cent. of the cases, and this in London where ether is most zealously advocated, to the exclusion, as far as possible, of chloroform."

On turning to the volume under review, there is seen, on p. 172 of the Statistical Tables (which are bound up at the end of the Reports), as follows:—

"The Statistics of Anaesthetics—During the year 1897 anaesthetics were administered 4,893 times.

Chloroform	1,959 times
Gas and ether	1,261 "
Gas	965 "
Gas and oxygen	477 "
Ether	201 "
Mixture of chloroform and ether	30 "

Total 4,893 "

As one of the administrators of anaesthetics to the hospital I should like to explain this table and to point out the error into which your reviewer has fallen.

For some years it has been the almost universal rule, in

these cases to which it is thought advisable to administer ether, to commence the administration with nitrous oxide gas, gradually to turn on the ether, and to continue its use alone until the operation is completed. Thus it will be seen that out of 1,462 cases in which ether was the chief anaesthetic used in 1,261 cases, the administration was begun with nitrous oxide gas, ether alone being given in 201 cases; indeed, I am surprised that the gas, as a preliminary, was omitted so often. This quite alters the ratio of ether to chloroform as pointed out by your reviewer, 1,462 out of 4,893, being nearly 33 per cent., instead of 4 per cent.

I am, Sir, yours truly,

EDGAR WILLETT, M.B., F.R.C.S.

25, Welbeck Street, London, W., October 12th.

HOMŒOPATHIC ASSURANCE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Under this title you have last week a leaderette, in which you refuse credence to Dr. Hayward's statistics of the comparative mortality under homœopathic, and ordinary, treatment of such diseases as yellow fever, cholera, and typhoid fever. With respect to yellow fever you "imagine that the number of patients suffering from this fell disease who underwent homœopathic treatment must be far too small for it to be possible to base any trustworthy conclusions thereupon." I have before me two pamphlets relating to the homœopathic treatment of yellow fever in New Orleans. The first is by a well-known homœopathic practitioner, Dr. William Holcombe, of New Orleans, entitled "Yellow Fever and its Homœopathic Treatment," published by Rodde, of New York, in 1856. It relates to the treatment of this disease in the epidemic of 1853, which "decimated the populations of New Orleans, Mobile, Vicksburgh, and Natchez, and some of the smaller towns and villages," by himself and Dr. F. A. W. Davis. Dr. Holcombe says:—"I treated 140 cases of yellow fever between the 13th of August and the 15th of December, 1853. None of them were cases of ephemeral sickness—nothing but unequivocal, strongly marked yellow fever was admitted into the list. Of this number 71 were white and 69 coloured, of the coloured 39 were blacks and 30 mulattoes. The adults were 93, children 47; cases in town 111, cases in the country 29; males 60, females 80. At least one-half of the cases were very severe, the patients being for several days in a critical and dangerous situation. Of the 140 cases, 9 died. Of these 6 were treated homœopathically by me from the beginning; 3 came into my hands on the fourth or fifth day of the disease, 2 of them having employed allopathic measures. Of the 6 treated with pure homœopathy from the beginning, one case was complicated with abortion and profuse hæmorrhage; another, a cachectic negro, died 6 weeks after the day of attack, in a typhoid condition—the sequel of yellow fever. Dr. Davis treated 415 cases, with 24 deaths. The combined result of our treatment was, therefore, 555 cases and 33 deaths, a mortality of 1 in 16.87, or 5.94 per cent."

The second pamphlet is entitled "Special Report of the Homœopathic Yellow Fever Commission, Ordered by the American Institute of Homœopathy for Presentation to Congress," published at New Orleans in 1879. This gives the reports of 24 homœopathic physicians hailing from 9 different localities; the total number of cases of yellow fever treated by them was 3,914, with a loss of 261 patients, a mortality of 6.6 per cent. The mortality under allopathic treatment could not be so accurately ascertained, but it was certainly not less than between 20 and 30 per cent.

I think you will allow that the number of cases treated homœopathically in these two epidemics was sufficiently large to base trustworthy conclusions upon.

With regard to cholera I will only mention two instances of the comparative results of the homœopathic and allopathic treatment of this disease. In the epidemic of 1836 the Homœopathic Hospital of Vienna, under the care of Dr. Fleischmann, was ordered by Government to be devoted to the reception of cholera patients, the disease being especially prevalent in

the suburb of Gumpendorp, where the hospital was situated. Here is what Sir William Wilde, in his book on Austria, says (p. 275): "Upon comparing the report of the treatment in this hospital with that of the same disease in the other hospitals in Vienna during the same period, it appeared that while two-thirds of the cases treated by Dr. Fleischmann, recovered, two-thirds of those treated by the ordinary methods in the other hospitals, died." I may mention that this striking testimony to the superiority of the homœopathic over the ordinary methods, led the Government to repeal the ordinances prohibiting the practice of homœopathy in the Austrian States, which had hitherto disgraced—or, perhaps, you would say adorned—its statute books.

The other instance of a comparative trial of the two systems in the treatment of cholera occurred in London in connection with the epidemic of 1854. The London Homœopathic Hospital, then in Golden Square, devoted to the reception of cholera cases by order of the Government, and a treatment committee appointed by the Royal College of Physicians, sent Dr. MacLoughlin to inspect and report on the cases treated, which amounted to 61, of whom 10 died, giving a mortality of 16·4 per cent. The mortality in the other hospitals, under allopathic treatment, averaged 51·8 per cent. The inspector said, in a letter to Mr. Cameron:—"All I saw were true cases of cholera in the various stages of the disease, and I saw several cases which did well under your treatment, which I have no hesitation in saying, would have sunk under any other."

I am unable to give any comparative trials of homœopathic and allopathic treatment in typhoid fever, but the experience of Dr. Kidd, who was sent by the English Homœopathic Association to Bantry in 1847 to treat the sufferers from famine fever, which may be considered as a kind of typhoid, may be mentioned. In 67 days he treated 111 cases, of whom only two died. During the same time 254 cases were treated allopathically in the Bantry Union Hospital, of whom 35 died. Thus, while the mortality under homœopathic treatment was only 1·8 per cent., that under allopathic treatment was 13·7 per cent.

The foregoing statistics relative to the three diseases you have mentioned will, I think, show that homœopaths do not deserve your censure that they resort to "the arts of the mountebank to bolster up their system."

I am, Sir, yours truly,

R. E. DUDGEON, M.D.

63, Upper Berkeley Street,
October 6th, 1899.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—You are quite right to insist on having the actual figures when statistics are quoted, whether homœopathic or otherwise, but before condemning Dr. Hayward and all his brethren for want of candour, it might have been better to have ascertained if the published report of his lecture contained all he had said on this matter. As you wish for the actual figures I will, with your leave, supply them. You are mistaken in supposing that homœopathy is not largely used in the treatment of yellow fever, in both North and South America. The epidemic to which I presume Dr. Hayward referred was that which occurred in Rio de Janeiro in 1851. Dr. Martins and three other homœopaths treated among them 3,256 cases, with 227 deaths—under 7 per cent. In the terrible epidemic of 1853, which occurred in New Orleans, Drs. Holcombe and Davies, homœopaths, treated between them 555 cases, with 33 deaths—under 6 per cent. During the epidemic which occurred between 1853 and 1878, the homœopathic practitioners, whose number was being constantly added to, treated altogether 6,569 cases, with 360 deaths—under 5½ per cent. During the same period there were treated allopathically 23,540 cases with 4,056 deaths—over 17 per cent.

The cholera statistics of homœopathy are the best advertisement that homœopathy ever had, and luckily they are vouched for by allopathic authorities. Sir

William Wilde, the well-known oculist of Dublin, in his work on Austria says (p. 275):—

"Upon comparing the report of the treatment of cholera in this hospital [the hospital placed by the Government of Austria under the control of Fleischmann, the homœopath] with that of the same disease in the other hospitals in Vienna during the same period, it appeared that while about two-thirds of the cases treated by Dr. Fleischmann recovered, two-thirds of those treated by the ordinary methods in the other hospitals died." These results had the effect of causing the Government to repeal the laws which had previously been in force against homœopathy in Austria. The statistics of the London Homœopathic Hospital, then in Golden Square, in the epidemic of 1854, were no less striking. The mortality was 16·4 per cent., as against 51·8 per cent. in the other hospitals. These figures were vouched for by the Government inspector, Dr. MacLoughlin, who wrote to one of the medical officers: "All I saw were true cases of cholera in the various stages of the disease, and I saw several cases which did well under your treatment, which I have no hesitation in saying would have sunk under any other."

I am, Sir, yours truly.

JOHN H. CLARKE.

Clarges Street, W., October 12th, 1899.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am not displeased with your editorial comments on some of the assertions made in my lectures at the Hahnemann Hospital, except the snarl as to addressing the uncritical laity. As a fair-minded editor you will, of course, allow me to explain the points you complain of.

I am not surprised that the statement that "while the average mortality from yellow fever is 27·7 per cent., the mortality under homœopathic treatment is only 7," should appear "very remarkable" to the editor of an ordinary medical journal; still, it is possible it may be quite true for all that. Nor am I surprised that you should imagine the numbers of yellow fever patients treated homœopathically are too small to draw conclusions from, because the work and writings of those members of the profession who practice homœopathically are so studiously ignored that you do not know what is being done by them. It may, perhaps, be news to both yourself and your readers to be told that in sub-tropical and tropical America, where yellow fever abounds, there are scores of homœopathic practitioners; and that they have gone through epidemic after epidemic, and treated thousands of cases of "this fell disease," of which reports have been furnished at the request of the Government; and that the statistics have been collected and compared times out of number, not by taking one epidemic but several, and making averages honestly and fairly. These statistics are given in the "North American Quarterly Homœopathic Journal" and the "British Quarterly," where they are compared with those furnished in the ordinary medical journals, as to the same epidemics and under the same circumstances. It is true the comparisons are not made in the latter journals, and for good reasons. By these statistics it will be seen that 7 per cent. is quite a high percentage under homœopathic treatment. And as to ordinary treatment, let Mr. Manson be heard; he is one of the highest and most recent authorities on the subject. On page 136 of his most excellent treatise on "Tropical Diseases," writing on yellow fever, he says:—"The mean mortality in the whole 269 cases was 27·7 per cent. This may be taken as a fairly representative mortality in yellow fever among the unacclimatised, something between 25 and 30 per cent., although in some epidemics it has risen as high as 50, or even 80 per cent. of those attacked." So my statement is not at all wrong.

As to cholera, you yourself know quite well that the average mortality under ordinary treatment is not less than 50 per cent. And in his address on cholera, as president of the National Health Society, the late Mr.

Ernest Hart, as reported in the *British Medical Journal*, said:—"Once established, and in well-marked cases of Asiatic cholera, drugs will do little to cure. The mortality of cholera all over the world, and in all epidemics, had defied drugs, and varied according to the intensity and the age of the patient, from 45 to 64 per cent." Contrast this with the following result of the treatment in the London Homœopathic Hospital:—"From these it appears that the number of cases treated in this hospital was 61, of whom 10 died, giving a mortality of 16·4 per cent. From the report issued by the Treatment Committee it was seen that the mortality in the other metropolitan hospitals averaged 51·8 per cent. The Government inspector of the London Homœopathic Hospital, Dr. MacLoughlin, wrote to Mr. Cameron, one of the medical officers of the hospital. "All I saw were true cases of cholera in the various stages of the disease, and I saw several cases which did well under your treatment, which I have no hesitation in saying would have sunk under any other?" So here, too, I am within the mark.

As to typhoid, why should the statement that "homœopathic treatment can do much to modify the course and shorten the duration," excite contempt, as you say, when the present boast of the profession is that "simple open-air treatment" can, and does, cut short and cure such a germ disease as tuberculosis; and "sunshine" treatment can do the same for some skin diseases of germ origin, as is now being put forth in orthodox medical journals? And whilst another great boast is that of the rapid cure of diphtheria, cholera, plague, tetanus, and other germ diseases by ordinary practitioners with antitoxins, and even of typhoid with anti-typhoid serum? These boasted cures of germ diseases by ordinary practitioners with antitoxins and animal extracts are orthodox, and therefore admissible; but to make a similar claim for ordinary medicines is only "to excite contempt." Could prejudice further go? Surely the shibboleth that "germ diseases must run their course" is an acknowledgement of impotence disgraceful to the profession; and the sooner the better it is allowed to follow into the limbo of discarded heresies the fiction of the "change of type in disease."

As to appealing to the laity, that is the fault of the members of the profession. They were invited, and several by "complimentary ticket," the course being addressed to "medical men taking charge of steamers visiting Africa, or taking charge of trading stations out there," as well as to "missionaries and nurses." But only four non-homœopathic practitioners were sufficiently open-minded to put in an appearance. We would much prefer to appeal to our professional brethren, but we are not allowed, professional societies and journals being closed against us! I am, Sir, yours truly,

JOHN W. HAYWARD, M.D.

Birkenhead, October 6th, 1899.

[We cannot deny the right of explanation to a correspondent whose statements as to comparative mortality are called in question, however widely we may differ from him. We prefer to leave his figures to the judgment of our readers, and it is hardly to be supposed that any of them will be prepared to accept without further inquiry the assertion relating to the "scores of homœopathic practitioners" whose experiences are published in the *North American Quarterly Homœopathic Journal*. We are asked to believe that a normal mortality of 27·7 per cent. has fallen to 7·0 per cent. under treatment by homœopathy, but before doing so we should require to know how much confidence the statements of these transatlantic authorities are entitled to inspire, and whether the methods of treatment which they employed were really those associated with the name of Hahnemann. We are, however, indisposed to lend our columns to the discussion of the merits or demerits of homœopathy, for at this time of day such discussion could serve o useful purpose.—ED.]

Literary Notes and Gossip.

MESSES. WRIGHT AND Co., of Britol, publishers of the "Medical Annual" announce a "Synoptical Index to Drugs and Treatment," for the twelve years 1887 to 1898, during which the Annual has appeared, for the purpose of gathering up in concise form all the references to treatment, &c., from the world's literature which are to be found there.

WE understand that the *Scottish Medical and Surgical Journal*, which was started some two years since as an opponent to the *Edinburgh Medical Journal*, will be taken over by a company on January 1st, 1900, with a view to improving and extending same. Dr. Wm. Russell will remain editor as heretofore, and Dr. Norman Walker has been appointed sub-editor and business manager. Two or three medical journals are now run on company lines, but so far we have not heard of any big dividends.

THERE has not been a great rush of new books in medicine or surgery this season so far, and we congratulate authors and publishers alike. At times books and their producers appear to vie with each other in the plenitude of excessive redundancy, and one wonders how many, or rather how few, of the new ventures will be rescued from the waste-paper market.

THE present season, however, appears to be an exception to the plethoric rule of October, as but two large books have reached us, and only two or three smaller ones. The two larger works are manuals of surgery, one, a new edition by Messrs. Rose and Carless, which has already made a distinct mark, and is perhaps to-day the most popular "surgery" extant; the other, on similar lines and of similar dimensions, by Mr. T. Pickering Pick. The latter we merely announce, not having yet had time to examine into its merits.

Of the smaller tomes, we have "An Introduction to Diseases of the Nervous System," by Dr. H. Campbell Thomson; "Difficult Digestion due to Displacements," by Mr. A. Symons Eccles, M.B.; "Differential Diagnosis," by Dr. Fred J. Smith; "Raynaud's Disease," translated from the French by Dr. T. K. Monro; and a manual of "Modern Gastric Methods," by A. Lockhart Gillespie, M.D., F.R.C.P., F.R.S.Ed., with a chapter on mechanical methods for young Children, by John Thomson, M.D., F.R.C.P., Ed.

NOR are the announcements of new editions so numerous as usual. A third edition of Sir Wm. Broadbent's "Diseases of the Heart" is expected this month. A fourth edition of Mr. Hy. Sewill's "Manual of Dental Surgery," a second edition of Prof. Mayo Robson's "Diseases of the Gall-Bladder," and an eighth edition of Dr. Macnaughton-Jones' "Diseases of Women," are in the press; and a new edition of "Intestinal Obstruction," by Mr. Frederick Treves, F.R.C.S., is just ready.

A NEW quarterly journal of "Climate" issued under the auspices of the Council of Livingstone College, and edited by Dr. C. Harford-Battersby, has just made its appearance. The object of the college is the instruction of missionaries in the elements of practical medicine, for the care of their own health, and to render simple help to native races far removed from medical aid. The object of the Journal is to afford an opportunity for an interchange of opinions on health questions by those who have had experience in various parts of the world. Both are excellent ideas, and we wish them an unqualified success.

"A GUIDE to Urine Testing for Nurses and Others," by Mark Robinson, L.R.C.P., &c., published by John Wright and Co., of Bristol, may prove useful to nurses "and others" employed in provincial hospitals and Poor-law infirmaries where the services of no clinical clerk are available. It is very difficult to draw the line at which to stop when initiating "nurses and others"

in the details of urinary analysis, and the author has been wise in limiting the chapter on the microscopical examination of urine to the bald statement that it is not within the nurses' province, though in truth this makes rather a short chapter. For the rest, the instructions are given in simple language, and will adequately fulfil the purpose for which they are intended.

THE "Handbook to South African Health Resorts," published by Messrs. Donald Currie and Co., has surely been issued at a singularly inopportune moment. It would require more vivid word painting than even the author can command to induce invalids to hie to the Cape under existing circumstances. The effect of the charming little views which solicit our admiration here and there throughout the book is stultified by the knowledge that many thousands of men are now on their way thither for purposes far removed from the pursuit of health. We would not advise any one either to rely too much on the details given in the chapter on the railway system, for "circumstances alter cases," and the most carefully prepared time tables are apt to be dislocated by warlike operations. So long as the traveller sticks to one of Messrs. Donald Currie and Co.'s magnificent steamers he may have no cause for anxiety or regret, but as to landing—that is quite another matter. On the whole we prefer to place the book on one side until the clouds have rolled by.

Medical News.

King's College, London.

THE following Entrance Scholarships have been awarded:—Medical Entrance Scholarship—70 guineas, A. J. Wigmore. Two Sambrooke Medical Exhibitions—£260, E. L. Holland; and £40, T. H. Jones and J. James, aeq. Two Clothworkers' Company Science Exhibitions—£30 for two years, V. E. Kingsbury; and £20 for two years, F. C. McCombie. Engineering Entrance Exhibitions—£15, W. J. Marlow; £10, A. H. Imber; £10, W. A. Sadgrove.

The Mortality of Foreign Cities

THE following are the latest official returns, and represent the last weekly death-rate per 1,000 of several of the populations:—Calcutta 42, Bombay 32, Madras 37, Paris 15, Brussels 15, Amsterdam 14, Rotterdam 15, the Hague 12, Copenhagen 14, Stockholm 17, Christiania 16, St. Petersburg 21, Moscow 23, Berlin 19, Hamburg 13, Munich 28, Vienna 16, Prague 19, Buda-Pesth 15, Rome 15, Turin 15, Venice 14, Cairo 43, Alexandria 32.

Deaths from Chloroform.

A death from chloroform asphyxia was the subject of an inquest at Stamford last week, the victim being a child who was about to undergo an operation for strangulated hernia. As is usually the case, no details were elicited as to the method in which the chloroform was administered, or the amount that had been employed, and the medical evidence favoured the view that the amount of chloroform used and the strength of the patient were factors of no importance. It is distressing to witness this unscientific attitude towards fatalities which are in large proportion, strictly speaking, avoidable. The mechanism of the production of death from chloroform narcosis is well understood at present, and there is no longer any mystery surrounding it. In this instance the existence of a strangulated hernia goes far to explain the untoward result, but we could have wished for evidence of the use of a suitable apparatus.

ANOTHER death from chloroform was inquired into by the St. Pancras coroner on Friday. The victim was a child, *et.* 4, who had suffered from diphtheria upon whom Dr. Cremin was about to perform tracheotomy, but the child promptly succumbed to chloroform narcosis. No information was forthcoming either as to the method employed, or the amount used, and a usual verdict was returned.—At Matlock, a young woman, *et.* 24, appears to have succumbed to the effects of less than two-pennyworth of chloroform, obtained for the purpose of alleviating toothache. She appears to have wrapped her head

up closely, and to this is attributed the fact that death resulted, though the quantity inhaled probably did not exceed 25 minims.

University College, Liverpool.

IT is announced that Mrs. George Holt and her daughter, Miss Emma Holt, have each contributed £5,000 towards the Physical Laboratory. With the generosity which does them honour these ladies had already subscribed £2,000 to the Medical School and £3,000 to the Anatomical School.

A Needle in the Heart.

AT an inquest held on Saturday last on the body of an elderly lady who was known to be addicted to the hypodermic use of morphia, it was stated at the post-mortem examination a needle was found embedded in the heart which had determined hemorrhage severe enough to cause death. No trustworthy history could be obtained of the way in which the needle had found its way thither, but her son stated that about four months ago the deceased thought a needle which she was using had entered her ear. Whether there was any connection between these two things is a matter which must remain in doubt, though the tendency of pointed bodies of small dimensions to travel considerable distances inside the body is well known and has often been recorded. A verdict of accidental death was returned.

Irish Medical Schools' and Graduates' Association.

THE Autumn General Meeting of this Association will be held in London at the Hotel Cecil on Wednesday, Nov. 29th, at 6.30 p.m. The dinner of the Association will be held on the same evening at 7.15 in the same building, the President, Sir William Thomson, in the chair. Later on, at 9.30 o'clock, the coming of age of the Association will be celebrated by an "at home." The cost of dinner tickets for members and their guests, exclusive of wine, but including subsequent admission to the "at home," will be 10s. 6d. each. The cost of tickets for admission to the "at home" only will be 4s. each. This being an unique occasion in the history of the Association, it is hoped that members and their guests will muster in large numbers. Applications for tickets, accompanied by remittance to cover cost thereof, together with the names of guests, should be forwarded as early as possible to Mr. P. J. Freyer, Hon. Sec., 46, Harley Street, W.

Society for Relief of Widows and Orphans of Medical Men.

AT a quarterly court, held on Wednesday last, Mr. Christopher Heath, V.P., in the chair, six new members were elected, and the death of Mr. Mould, a vice-president, and at one time a very active member of the society, was reported. The death of a widow was announced, who had received £50 per annum since July, 1894. A first application for a grant was read from a widow, and a grant at the rate of £40 per annum made. Applications for renewal of grants were received from 48 widows, 12 orphans, and six recipients from the Copeland Fund, and it was resolved to distribute at the next court among them the sum of £1,201 10s. The directors were pleased, on the report of the acting treasurer, to be enabled to vote a sum of £541 to be given as a Christmas present to the widows and orphans on the funds of the Society, viz., £10 to each widow, £3 to each orphan, and £5 to five recipients from the Copeland Fund. The expenses of the quarter were £62 10s.

University of Glasgow.

AT the recent professional examinations for the degrees of M.B., Ch.B., the following candidates passed with distinction in the subjects indicated:—

FIRST EXAMINATION.—In Botany.—Henry Crame Anderson, John Baird Morton, William Templeton. In Zoology.—James Glover, Anna Pollock Martin, Berkeley Hope Robertson. In Physics.—Carl Hamilton Browning, John Muir Kelly, David Robertson Mitchell, John Murdock, Robert Tait Wells, M.A. In Chemistry.—Isabel Deane Mitchell.

SECOND EXAMINATION.—In Materia Medica and Therapeutics.—Robert Wellwood Auld, Samuel James Cameron, James Bertie Wylie Cook, William Dick, James Grant Millar, John Paton, John Walker Renton, Elizabeth Ness MacBean Ross, Donald Steel, Joseph Goodwin Tomkinson, John Unsworth.

THIRD EXAMINATION.—In Medical Jurisprudence and Public Health.—Lizzie Thomson Fraser, James Dunlop Lickley, William Barr Inglis Pollock, Alexander Dey Thompson.

Notices to Correspondents, Short Letters, &c.

A QUESTION OF ETIQUETTE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I was called in a few days since by the landlady of the house to an inmate who had taken a poisonous dose of laudanum. On my arrival I was confronted by a *confreere*, who promptly told me the case was his, as he had been there an hour. I asked him what he had done, and finding that he had done nothing beyond injecting strychnine, I took upon myself there and then to wash out the stomach with a solution of permanganate, and to secure the services of two nurses to keep the patient moving. She ultimately recovered, but I am charged with a breach of etiquette in that I interfered in another man's case. I must admit that I did so, but it was by reason of the extreme urgency of the case, and the apparent inability of the man in charge to "do the necessary," he having neither stomach-pump nor antidote case at hand.

Ought I to forego my fees and tender an apology, or am I at liberty to claim that the case was one in which the combined efforts of two practitioners were not *de trop*? I am anxious to do the proper thing, and shall be glad of your opinion.

I am, Sir, yours truly,
ANTIDOTE.

*. It would probably have been best to suggest the necessary steps to the "man in possession," instead of carrying them out independently, but in such an urgent case, it must be admitted, too strict a regard to etiquette would be out of place. It ought not to be difficult to "square" matters on a friendly footing, because there is nothing to prevent both practitioners from claiming their respective fees. A friendly assurance of respect and esteem to the medical man originally called might advantageously take the place of an apology.

DR. J. LAMOND LACKIE (Edinburgh).—An engraving is being made, and space will be given to your interesting case in an early number.

THE IMMUNITY OF BIRDS TO SEWER GAS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have had opportunities of studying the development of sundry families of sparrows whose parents had selected the patulous ends of soil pipes and sewer ventilators for their homes. In view of the lethal properties with which sewer and drain air is credited, it occurred to me to watch them in order to ascertain what effect, if any, the habitual breathing of this contaminated air would have on their health and growth. So far as my observations went the young birds seemed to thrive admirably, and I was never able to detect any sign of ill-health or retarded development. They were plump and quitted home at the usual period.

I do not advance these observations as an argument for admitting sewer gas to our dwellings, but either animals, or some of them, are immune against such sources of infection, or we greatly overrate their virulence.

I am, Sir, yours truly,
V. G.

Meetings of the Societies and Lectures.

WEDNESDAY, OCTOBER 18TH.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—4 p.m. Dr. G. Vivian Poore: Harveian Oration.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—4.30 p.m. Dr. T. D. Savill: Ringworm Favus and Pityriasis Versicolor. (Post-graduate course.)

THURSDAY, OCTOBER 19TH.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 p.m. Cases and Card Specimens. 8.30 p.m. Mr. A. Critchett (President): Introductory Address. Papers:—Mr. R. W. Doyno: (1) Notes on the Value of Radiant Heat in Eye Disease: (2) Notes on Recurrent Superficial Necrosis of the Cornea.—Mr. J. B. Lawford: Keratitis in Acquired Syphilis.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Tichborne Street, Egham Road).—Clinical Evening.

FRIDAY, OCTOBER 20TH.

SOCIETY OF ANESTHETISTS (Cafe Monico).—6.30 p.m. Annual Meeting. 7.15 p.m. Annual Dinner.

Vacancies.

Bethlehem Hospital, London.—Two Resident House Physicians for six months. Apartments, complete board, and washing provided, and an honorarium at the rate of £12 12s. each per quarter will be paid. (See advt.)

Brighton, Hove, and Preston Dispensary (Northern Branch).—House Surgeon. Salary, £160 per annum, with furnished apartments, coals, gas, washing, and attendance.

County Asylum, Prestwich, Manchester. Assistant Medical Officer, unmarried. Salary commencing at £125, with board, apartments, and washing.

County of London Manor Asylum, Horton, Epsom, Surrey.—A Dispenser. Salary, £110 per annum, rising £10 a year to £150, with dinner daily. Apply to the Clerk of the Asylum Committee, Office, 6, Waterloo Place, London, S.W.

Glamorgan County Council and Cardiff Corporation.—Bacteriologist to the Joint Committee and Lecturer on Bacteriology in the University of Cardiff. Salary as Bacteriologist and Lecturer, £300 a year. Apply to the Clerk, Glamorgan County Office, Cardiff.

Hospital for the Insane, the Coppice, Nottingham.—Assistant Medical Officer, unmarried. Salary £150 per annum, with apartments, board, attendance, and washing.

Lincoln County Hospital, Lincoln.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging and washing.

Nottingham General Dispensary.—Senior Resident Surgeon, unmarried. Salary £180 a year, increasing by £10 annually to £200. Special arrangement for board, &c.

Parish of Hammersmith.—Medical Officers and Public Vaccinators for the First and Fourth Districts of the Parish. Apply to the Clerk, 75, Fulham Palace Road, Hammersmith, W.

Royal Infirmary of Edinburgh. Superintendent. Salary £500 per annum, with free house, coals, and light.

St. Andrew's Hospital for Mental Diseases, Northampton.—Junior Assistant Medical Officer, unmarried. Salary commencing at £150 per annum, with board, apartments, and washing. Salary increasing £25 per annum to £200.

Sussex County Hospital, Brighton.—House Physician, unmarried. Salary commencing at £50 per annum, and board, residence in the hospital, and washing. Application to the Secretary.

Victoria University, Manchester.—External Examinership in Anatomy for three years. (See advt.)

Appointments.

BUXTON, EDWARD, M.D., F.R.C.S., M.R.C.P., Ed., D.P.H. Medical Officer of Health for the Little Crosby and Hightown Districts.

DIXON, W. E., B.Sc.Lond., M.B., L.R.C.P., M.R.C.S., Assistant to the Downing Professor of Medicine, University of Cambridge.

FAULKNER, HUGH, M.B., Ch.B.Edin. House Physician to the General Hospital, Birmingham.

FORBES, W. J., M.B., C.Ch., B.A.O., R.U.I. Medical Officer of Health for the Knaresborough Rural District.

HUEY, JOHN J., L.S.A.Lond. Medical Officer of Health to the Mexboro' Urban District.

HUMPHRY, L., M.A., M.D.Camb., M.R.C.S. Assessor to the Regius Professor of Physic, University of Cambridge.

HUTTON, EUSTACE, M.R.C.S., L.R.C.P.Lond. Visiting Surgeon to the Stockport Infirmary.

MITCHELL, ARTHUR M., M.A., M.D., B.C.Cantab. Honorary Assistant Medical Officer to the Royal Surrey County Hospital, Guildford.

RATRAY, P. W., M.B., C.M.Aberd., F.R.C.S.Eng. *Pro tem*. Medical Superintendent of the Workhouse of the Parish of Islington.

REED, JOHN ARTHUR, M.B., Ch.B.Vict. House Surgeon to the Stockport Infirmary.

STEPHEN, SOUTHALL, M.B., Ch.B.Edin. House Surgeon to the General Hospital, Birmingham.

THORP, HAROLD, M.B.C.S., L.R.C.P.Lond. Junior House Surgeon to the Warrington Infirmary and Dispensary.

Births.

NEILL.—On Oct. 12th, at Ranaghat Medical Mission, the wife of Charles Neill, M.A., M.B., Camb., of a son.

PINKERTON.—On Oct. 13th, at Trevanno, South Norwood Hill, the wife of Robert L. Pinkerton, M.A., M.D., of a daughter.

SOUTH.—On Oct. 10th, at Church Close, Boston, Lincs., the wife of Richard E. South, J.F., L.R.C.P., M.R.C.S., of a daughter.

WILLIAMS.—On Oct. 13th, at 1, Somerset Place, Stoke, Devonport, the wife of Dr. J. O. B. Williams, R.N., of a son.

Marriages.

EHKKE-CASTLE.—On Oct. 10th, at Claines Church, Worcester, Frank Ehrke, M.D., of Kempsey, to Emmeline Dora, daughter of the late Charles Castle, Esq., D.L., J.P.

LANDER-SIMON.—On Oct. 12th, at St. Mark's Church, Dalston, Harry, eldest son of H. Longley Lander, of Clapham Common, to Liesel Jean, eldest daughter of George C. Simon, M.D., C.H.M., of Hackney.

MACPHERSON-NASH.—On Oct. 14th, at St. Peter's Church, Bayswater, William Hugh Macpherson, M.A. Cantab., M.R.C.S., of Henley-on-Thames, son of Sir Arthur George Macpherson, K.C.I.E., to Maud Hollick, fourth daughter of Edmund Nash, M.D., of 125, Lansdowne Road, Notting Hill.

POLEHAMPTON-DAVIE.—On Oct. 9th, at Victoria, British Columbia, Frederick W. Polehampton, second son of the late Rev. Edward T. W. Polehampton, Rector of Hartfield, Sussex, to Kathleen Eunice, youngest daughter of John Chapman Davie, Esq., M.D., of Victoria, British Columbia.

Deaths.

BANKS.—On Oct. 11th, at Golagh House, Monaghan, Alice, dearly beloved wife of Sir John Banks, K.C.B., M.D., of 45, Merrion Square, Dublin.

BARNES.—On Oct. 12th, John Wickham Barnes, F.R.C.S., of Bolt Court and Stanwell Moor, Hon. Sec. Poor Law Medical Officers' Association, late Secretary Medical Society of London.

FLOWER.—On Oct. 7th, at Beaufort West, Bath, Thomas Bruges Flower, F.R.C.S.Eng., aged 84 years.

HORTON-SMITH. On Oct. 8th, R. J. Horton-Smith, M.A., M.B. Cantab., youngest surviving son of R. Horton-Smith, Q.C., aged 26.

MOULD.—On Oct. 10th, at 1, Onslow Crescent, London, S.W., John Thomas Mould, F.R.C.S., in his 82nd year.

RYAN.—On Oct. 1st, at his residence, 13, Idrone Terrace, Blackrock, co. Dublin, Michael Ryan, M.D., F.R.C.S.E., in his 86th year.

THE NERVOUS LESIONS OF CONGO SICKNESS (a)

By F. W. MOTT, M.D., F.R.C.P.Lond.,

Pathologist to the London County Council.

THE author related the results of the investigation of the central nervous system in two cases of Congo sickness, and he showed a number of lantern slides and microscopical specimens. The brain and spinal cord, pituitary body and spinal ganglia were examined. To the naked eye the tissues in Case 1 presented but little change beyond some slight thickening of the pia-arachnoid. The convolutions of the brain were complex and not atrophied. The organ weighed 54 ozs. The two hemispheres were of equal weight, and there was no excess of fluid. In Case 2, the younger patient, the dura mater was found adherent to the skull cap. There was a considerable quantity of cerebro-spinal fluid. The pia-arachnoid was somewhat thickened and opaque over the convolutions. The base of the brain likewise showed thickening and opacities of the pia-arachnoid: weight of the brain, 36 ozs. Neither of the brains showed flattening of the convolutions, erosions on stripping the membranes, or dilated ventricles with granular ependyma. The nervous tissues before mentioned were removed so soon after death as to avoid post-mortem infarctions. Portions of different parts of hemispheres, cerebellum, pons, medulla and cord, also spinal ganglia, were stained by Nissl method, Marchi and Marchi-Pal methods, after suitable hardening and fixation. The microscopical examination of these sections exhibited in both instances similar conditions. There was a leptomeningitis and encephalo-myelitis throughout the whole central nervous system, but especially in the medulla and base of the brain, sections showed all the perivascular lymphatics distended with more nuclear leucocytes. The left cerebral hemisphere in case 2 showed this condition in an especially marked manner, very probably accounting for the right-sided fits from which this patient suffered towards the end of life. Sections were also stained by Gram method, Pfeiffer, and other methods, but with negative results, thus agreeing with the negative evidence obtained by Dr. Bullock, who examined the blood and lymphatic glands removed from Case 2 during life. Some of the cerebro-spinal fluid removed from Case 2 after death yielded by culture various organisms, but this evidence is of no value, because rigid precautions were not taken in obtaining the same; moreover a large bed sore existed over the sacrum.

General and Special Appearance of the Nerve Cells:—In Case 1 the outline of the nerve cells and their arrangement appeared fairly normal, neither was it considered that the neuroglia cells were

markedly increased. The columns of Mynhert in the cortex cerebri were distinctly evident, thus contrasting with the appearances of the brain in general paralysis. The cells themselves throughout the whole nervous system showed a uniformly dull diffuse staining reaction, and in none of the cells were the Nissl granules evident. This change was certainly due to the hypopyrexia. In Case 2 the cells for the most part presented a normal outline and exhibited Nissl granules on the dendrons and in the body of the cell. In the medulla, however, a considerable number of cells showed chromolytic changes, and to a less degree changes were found in the motor cells of the anterior cornua. The cells in the left hemisphere showed degenerative changes in sections of the motor area. Mynhert's columns were not distinctly visible, and many of the cells seemed atrophied and broken up.

Fibres:—Sections of the brain and cord were stained by Marchi, and Marchi-Pal methods. Nothing abnormal was found in Case 1, except perhaps the tangential fibres were not so numerous as in the normal cortex cerebri. In Case 2 there was obvious wasting of the tangential fibres in both hemispheres but especially of the left. There was slight sclerosis of the crossed pyramidal tracts of the cord, more marked on the right side, and also a number of recently degenerated fibres were exhibited by the Marchi method. The arteries of the central nervous system exhibited no trace of endarteritis. In the choroid plexus there were numerous microscopical psammomata. The central canal of the spinal cord was filled up by proliferated glia tissue. The posterior spinal ganglia showed the same appearances around the vessels, but the ganglion cells in case 1 only showed the diffuse staining of hypopyrexia, and in Case 2 exhibited a fairly normal appearance. Can the changes above referred to account for the symptoms? The changes in the left cerebral hemisphere of Case 2, together with the evidence of degeneration in the opposite crossed pyramidal tracts agrees with the convulsions of the right side observed during life. No doubt these convulsions were the expression of the increased irritability prior to death of the cortical motor neurons. The symptoms, which were, however, present in both patients, and characteristic of the disease, viz., progressive drowsiness and lethargy, which eventually led to most of the lives of the patients being passed in sleep; and the progressive weakness in body and mind without, however, any distinct paralysis or mental disability, can best be accounted for by supposing that the metabolism or functional activity of the neurons as a whole is affected injuriously either by some toxic product circulating in the blood or existing in the cerebro-spinal fluid, that this toxic agent, whatever it may be, has occasioned an enormous proliferation of mononuclear leucocytes beneath the pia-arachnoid membrane and in the perivascular lymphatics. It might, however, be considered that

(a) Delivered before the Pathological Society of London, Tuesday, October 17th, 1899.

the functions of the nervous system were affected by an interference with their nutrient supply owing to the perivascular lymphatics being filled with leucocytes and thus interfering with the circulation of the lymph of the brain.

The liver, kidneys, lungs, pituitary body, spleen, lymphatic glands, and duodenum were also examined. The results were for the most part and with the exception of the duodenum and lymphatic glands, negative. The lymphatic glands were greatly enlarged owing to lymphocytes great increase. Sections of the duodenum showed a large number of lymphocytes and a proliferation of the same in the lymphoid nodules. It is a pity seeing that the French authorities have considered this disease to be due to the pneumococcus that lumbar puncture was not performed during life, and the cerebro spinal fluid examined for organisms.* The negative evidence as to the disease being due to a micro-organism is inconclusive, but it must be remembered that in rabies no micro-organism has been found. The facts mentioned may perhaps help towards elucidating the pathology of this disease.

They are also of interest in contrasting this affection with general paralysis, which by many authorities is still considered to be a primary meningo-encephalitis, yet although the appearances of inflammation in this disease are as intense and certainly more widespread than any case of general paralysis which I have seen, yet the cellular changes are in comparison with general paralysis slight; an argument, I think, in favour of the view that progressive paralysis of the insane is a primary disease of the neuron with secondary inflammatory changes.

*Annales de l'Institut Pasteur, March, 1899. Role du Pneumocoque dans la Path. et dans la Pathogenie de la Maladie du Sommeil. Par le Dr. E. Marchand.

Regis et Gaide have published (*Presse Medicale*, October 1st, 1896,) case observed in the region of Timbuctoo. They consider it to be a diffuse meningo-encephalitis of diffuse infective origin.

PHAGEDÆNA OF SIMPLE (OR SO-CALLED SOFT) SORES AND OF SYPHILITIC (OR SO-CALLED, HARD) CHANCER.

By H. DE MERIC, M.R.C.S.

Surgeon to the French Hospital.

THE two following cases which came under my care simultaneously at the French Hospital illustrate very clearly the difference in the phagedænic action affecting simple sores, and phagedæna when taken on by the syphilitic chancre.

CASE 1.—E. B., æt. 27, came to my out-patient room with a sore at the edge of the prepuce, just in front of the frænum. There was a history of three connections with different women during the preceding three weeks; after the first two connections he noticed what he described as small blisters on the glans penis, which disappeared in three or four days after the application of Vin aromatique. The patient stated that he tore himself slightly at the second connection, and bleeding took place from the tear; this solution of continuity had very nearly healed at the time of the last connection which took place eight days before he came to the hospital; the day after this last connection the tear became very painful, and on the day after, from the man's description, began to ulcerate; he applied vin aromatique, but as the ulceration continued to extend, he came to the hospital. There was then one unhealthy looking sore with rounded edges having a tendency to excavation of

the centre and to spreading at the borders, bathed in an abundant thick pustular discharge; the sore gave to the fingers a feeling of doughy hardness but no induration; nothing whatever could be felt in the groins. Taking into consideration the shortness of the incubation (barely two days) the appearance and feel of the sore and the absence of any glandular enlargement in the groins I regarded the sore (though single) as a simple or so-called "soft" sore, therefore I merely lightly brushed it over with nitrate of silver and gave the patient some lot. nigra to apply. After a few days another sore appeared posteriorly to the first one; this second sore had at first the appearance of a small punched-out hole, from which pus was oozing, this soon, however, became a definite sore similar to, though of course much smaller than, the first; the next time the patient was seen a third sore had appeared the other side of the frænum, this ran the same course as the second, both being evidently caused by direct inoculation from the first. In spite of treatment in the out-patient room all these sores got rapidly larger and larger, and eventually joining together formed one large ulcerating surface, which became phagedænic; the extension of the sore thus formed was towards the mucous membrane of the glans penis, *not* on the skin of the prepuce, but another sore had by this time made its appearance on the interior of the dorsal part of the prepuce; this was long and narrow and only extended laterally on the skin of the prepuce, *not* on the mucous membrane; it became phagedænic also, but the phagedænic action here was not nearly as intense as in the original sores. I now took the patient into the hospital (I wished to admit him before but he had refused to come in). During the first three days of his stay the sores continued to extend, the original sore both deeply and laterally, the one on the skin of the prepuce only laterally at each extremity, and this in spite of every care as to cleanliness, in spite of the application of nitrate of silver, in spite of the constant soaking of the part in lot. nigra, and in spite of the internal administration of $\frac{1}{2}$ gr. of proto-iodide of mercury (this I gave as a precautionary measure in view of the appearance of the last sore on the skin of the prepuce, although I ordered it *à contre cœur*, as I felt certain all the sores were simple and *not* syphilitic). On the fourth day I applied fuming nitric acid freely to the original sore, lightly to the other; at the same time I stopped the internal administration of mercury which I was convinced was useless for such a case. The effect was magical. The phagedænic action was at once arrested over nearly the whole extent of both sores and they gradually began to heal by granulation. In a week I had to apply the acid again to the centre of the original sore and to the ends of the preputial sore; twice more at intervals of three days the centre of the original sore had to be touched lightly with the acid. Both the sores were, during the whole time, dressed at short intervals, at first, with lot. nigra, and later, with lot. sod. chlorinatæ. During the next three weeks the sores healed up gradually; as cicatrisation proceeded, more and more difficulty was experienced in getting the foreskin forward after each dressing; this, perhaps, retarded the healing. During the whole time the patient was in the hospital, and during the subsequent three or four months of his reporting himself to me in the out-patient room, there never was the slightest enlargement of the glands in the groin, nor a trace of any eruption or of any other syphilitic symptom, confirming, if confirmation was necessary, the diagnosis. I may also mention that the man had never suffered in his life from any venereal complaint whatever.

CASE 2.—A. P., æt. 26, a weakanemic-looking man, came to my out-patient room having contracted a gonorrhœa which came on four days after connection

he had never had a venereal sore in his life, but had suffered from gonorrhœa five years ago; he had a very long foreskin which he had never been able to get back.

The case was treated with antiphlogistic internal remedies, and a weak lotion to inject, not only into the urethra, but also under the prepuce in conjunction with warm water. Twelve days afterwards the resident medical officer admitted the patient to my ward; the man was then suffering from very great pain on micturition, and the whole of the penis and foreskin was very red and inflamed. On the day after admission, the resident medical officer freely slit up the foreskin. As expected, there was a great deal of balanitis, together with a profuse discharge from the urethra. Ordinary remedies were applied, and the swelling and discharge diminished. A very small "écorchure" was noticed by the frænum a few days after admission, but this did not develop into a sore until eight days afterwards. During the subsequent four or five days this sore extended rapidly, developing great induration at the base, and becoming phagedænic, not, however, in the same manner as in Case 1, there not being the same tendency to excavation by loss of tissue, but the morbid action going on over the whole surface of the chancre with a tendency to extension at the edges, there being but little discharge as compared with that occurring in Case 1; the induration was essentially basic, and had none of the doughy feel remarked in Case 1; in fact, but for the phagedæna the whole chancre would have been raised above the surface, there being no rounded edges with a tendency to excavation at the centre of the sore as in Case 1. Specific treatment was commenced the instant the "écorchure" developed into a chancre; I had felt very much inclined to begin it on the first appearance of the "écorchure," especially as the glands in both groins were indolently enlarged, but taking into consideration the presence of the balanitis, which by irritation sometimes gives rise to quite innocent little sores, and the gonorrhœa which I have often found in weakly subjects to produce an enlargement of the inguinal glands, I considered it better to wait; I am also very much against giving mercury to a patient unless the diagnosis of syphilis be almost or absolutely certain. Black wash was locally applied. At first it seemed as if the application of fuming nitric acid would be necessary as in Case 1, but I refrained, for I felt certain the chancre was a *syphilitic* chancre, which would, even when phagedænic, be acted on by specific treatment, and, although for three or four days the chancre still *extended*, it never showed any tendency to *excavate*; on the fifth day the phagedænic action had evidently lessened, and from that time it gradually disappeared, the chancre, however, taking nearly two months to completely heal, leaving behind an enormous amount of induration. In the meanwhile the secondary eruption had come out with sore-throat, &c. I may mention that the extension in this chancre was never by *inoculation* as in Case 1; there were no little sores formed near the original one that gradually merged into it; on the contrary, all the extension was from the edges of the chancre, although sloughs formed over its whole surface, there was never any tendency to excavation of the centre.

The points of interest in these two cases may be considered under the heads of Diagnosis, Treatment, and Prognosis. With regard to the diagnosis of venereal sores it has been over and over laid down that simple sores are always multiple, and that the syphilitic chancre is, as a rule, single. This is perfectly true, but it must be borne in mind that the multiplicity of simple sores may not date from the beginning of the disease as there may have been only one portal of entry, in which case there will only be one sore until others form round it by inoculation, as happened in

Case 1; therefore we must not rush to the conclusion that a sore is syphilitic because it is *single*, if seen a short time after it has been acquired, but we must carefully sift the two most important points for our diagnosis, viz., length of incubation and glands in the groin. In Case 1 the incubation was about 24 hours (a little shorter than usual because at the time of contamination a tear existed on the penis giving an easy point for inoculation during connection), and there was not the slightest glandular enlargement: with simple sores there is either nothing at all in the groin or else an intense inflammation of the inguinal glands rapidly forming an abscess, there is *never* the indolent enlargement of these glands which accompanies syphilitic chancre. On the other hand we must not fall into the error of regarding the presence of two or three chancres to indicate the absolute fact of their being simple sores; it must be remembered that the syphilitic virus may find several portals of entry during a connection, in each of which a chancre will form, but no more chancres will subsequently be produced by *inoculation* as is the case with simple sores. The diagnosis of phagedæna attacking a venereal sore presents no difficulty, but the perusal of my two cases will show that the phagedænic action affecting the syphilitic chancre was not nearly so intense as that affecting the sore produced by the coalescence of several simple sores. In my experience, this is invariably the case, and I believe the reason phagedæna of a syphilitic chancre has been described as very acute, is that a tertiary gumma of the penis has been mistaken for a primary sore. When phagedæna attacks a venereal sore the importance of diagnosing, whether we have to deal with a simple or a syphilitic lesion, cannot be overrated, as the treatment is absolutely different, in the one being local, in the other almost entirely constitutional, as shown in my two cases. It is rarely necessary to apply strong nitric acid to arrest the phagedænic action in a syphilitic chancre, for the internal administration of mercury will do all that is necessary. A case in point I have recently had in private. A gentleman came to me with a primary syphilitic chancre which had just taken on phagedænic action. He could not lie up as he had to go abroad on business. I ordered mercurial pills internally, and black wash locally, but thinking I might hasten the disappearance of the phagedæna, I brushed over the chancre with *dilute* nitric acid on the two consecutive days before his departure; this did not produce any immediate improvement, but as I was certain the chancre was *syphilitic*, I felt he was quite safe if he took his pills regularly. In a fortnight he came back; the chancre was then nearly entirely healed, and he had a well-marked secondary eruption all over him.

With regard to the prognosis in my two hospital cases, it is evident that it is only serious in Case 2, from whom the poison of syphilis will have to be eradicated; whilst Case 1 is none the worse, excepting for some loss of substance of the penis.

THE SURGICAL TREATMENT OF FIBRO-MYOMATA.

By FREDERIC BOWREMAN JESSETT,
F.R.C.S.,

Surgeon to the Cancer Hospital, Brompton.

MR. BOWREMAN JESSETT alluded to the importance of the subject as shown by the great improvements of the technique in late years.

He then alluded briefly to the history of the operation for the removal of the uterus with its myomata attached, pointing out that Langenbeck was the first

to actually perform these operations, the results of his operations were, however, not satisfactory. Kæberle, in 1863, introduced the extra-peritoneal operation, and the use of the "serre-nœud," which was adopted in England until he (Mr. Bowreman Jessett) introduced his operation of pan-hysterectomy at about the same time as Dr. Heywood Smith reported some cases of the sub-peritoneal method of dealing with the stumps.

The question of morcellement and the removal of the adnexa was briefly touched upon, but neither of these operations met with his support. In discussing the treatment, Mr. Jessett considered the question under the following heads: viz., the subserous, intramural, submucous, combined subserous, and intramural. Polypoid fibro-myomata becoming malignant either sarcomatous or carcinomatous, and lastly fibromyomata complicated with pregnancy.

The subserous might be met with with long slender pedicle, in which case it could readily be removed by ligaturing the pedicle and not interfering with the uterus, or they might have a broad sessile base when the peritoneum could be divided and the tumour enucleated, the uterus still being left. In cases of intramural or combined subserous and intra-mural myomata in which operation was indicated, he recommended either complete hysterectomy, or the sub-peritoneal operation by the abdominal route; he, however, preferred the major operation, unless the patient were in an enfeebled condition and it was desirable to complete the operation quickly. In all cases of submucous fibro-myomata and polypoid growths the vaginal route was recommended; the cervical canal being dilated and the tumours enucleated; in case of hæmorrhage the uterus to be packed with iodoform gauze.

Complete hysterectomy by the abdominal route or by the combined vaginal and abdominal route was strongly advised for all cases in which the fibromyomata had taken a malignant action. The result in such cases in his hands had been most encouraging. In cases in which doubt existed it was recommended that the cervical canal should be dilated and the cavity curetted, the *d'bris* being examined microscopically. The consideration of myomata complicated with pregnancy was of very great importance, and great discretion was required to decide when to operate or not, as in many cases gestation proceeded normally and the fetus was born naturally, whereas in others the fetus was destroyed by pressure of the tumour, when, if prompt operative measures were not adopted the patient's life might be lost or seriously jeopardised. The question of producing abortion was touched upon, but on account of the great mortality attending this operation it was not recommended.

Vaginal hysterectomy for these cases could only be practised when the tumour was small, and the uterus easily drawn into the lower pelvis; in some cases the relation of the intestines to the tumours might be such that, by adopting this operation disastrous results may follow.

The method of performing the operation was alluded to, and the use of the forceps and angiotribe discussed, but he (the author) preferred the use of ligatures of properly prepared catgut or silk.

A VERY valuable contribution to the botanical department of the Dublin Museum has been made by Lady Leighton, sister of the late Lord De Tabley, consisting of 20,000 sheets of dried botanical specimens collected by his Lordship.

OBSERVATIONS UPON A NEW FISH FOOD.

By A. LOCKHART GILLESPIE, MD.,
F.R.C.P.E., F.R.S.E.,

Medical Registrar to the Edinburgh Royal Infirmary; Lecturer on Materia Medica and Therapeutics, Edinburgh School of Medicine.

THROUGH the courtesy of a professional brother, aware that such matters were of interest to me, I received some little time ago a quantity of a new food preparation, almost entirely derived from the flesh of white fish. As upon examination of the food its composition, theoretical food and nutritive values, both actual and in relation to its pecuniary aspect; its digestibility and the pleasant nature of its culinary preparations, were so striking, that I thought a note about them might prove useful.

Marvis, as the food is named—"maris" "vis," strength of the sea—is a white, or very slightly yellow, powder, scarcely distinguishable from flour to the eye, with a slight odour such as is common to all fish. The powder is dry, does not adhere in lumps, and mixes easily with water, hot or cold. It consists of the flesh of fresh white fish, newly caught, freed from skin, large bones, and viscera, thoroughly cooked, and finally minutely powdered by special machinery, the finer bones of the fish being similarly treated along with the muscle.

A small proportion of flour is added to the fish product to facilitate a proper mechanical suspension of the powdered muscle and bone, on being mixed with fluids. The resulting compound is, as stated above, a homogeneous powder closely resembling flour, with a high nutritive value, and a food-stuff which can be kept practically for any length of time unaltered.

Marvis is manufactured at a northern seaport town, where the fishing industry is of prime importance. The fish used can thus be and are procured on the spot, fresh from the sea; a point of much weight when the liability for fish flesh to undergo rapid post-mortem changes is considered. The Marvis powder, as I have seen it, has undoubtedly been prepared from fresh material, and as the muscle juice or serum is largely removed during manufacture—the juice is the first part of the fish to decompose, and the part with the strongest fishy odour—the powder is not liable to go wrong, nor has it nearly such a pronounced fishy smell, owing to the absence of its chief source, the serum.

The novel characteristics presented by this food-preparation led me to examine it more closely.

Analysis of the powder gives the following results expressed in percentages:—

Moisture driven off at 110 degs. C.	Total Solids.	Inorganic Ash.	Organic Solids.
11.9	88.1	3.35	84.75

The ash, therefore, forms 3.8 per cent. of the dried solids.

The nitrogen, estimated by Kjeldahl's method, is 8.6 per cent., or equal to 54.25 per cent. of proteids, if it be regarded as being present entirely in proteid bodies. Compared with the dried total solids the proteids amount to 61.5 per cent., or 64 per cent. of the total organic material.

ORGANIC SOLIDS.

	P. c. to Total.	Total p. c. to Organic Solids.
Total	84.75 p. c.	
Proteid	54.25 "	64 p. c.
Fats	2.5 "	2.98 "
Carbohydrates	15.0 " (circa)	17.69 "
Undetermined	13.0 " (of which phosphorus 0.31 p. c.)	15.33 "

INORGANIC ASH.

	P. c. to Total.	P. c. to Total Ash.
Total	3.35 p. c.	
Chlorides (as NaCl)	0.217 "	6.47 p. c.
Phosphates (as Na_2HPO_4)	1.50 "	44.7 "
(as P_2O_5)	0.75 "	

ORGANIC PHOSPHORUS.

0.73 p. c. (as P_2O_5)
1.07 " (as H_3PO_4)

TOTAL PHOSPHORUS (as P_2O_5).

1.48 p. c.

77.9 per cent. of the organic solids were dissolved and acted upon by pepsin and hydrochloric acid in artificial digestion experiments, practically the whole of the nitrogenous substances undergoing digestive changes.

Cold water dissolved 6.43 per cent., boiling water 3.33 per cent. of the total from the residue left. Both extracts contained native and derivative proteids among other substances.

The percentage of total phosphorus is high. Katz (Pflüg. Arch., Bd. 63) obtained 1.035 per cent. from the muscle of pike, as P_2O_5 , 0.83 per cent. in inorganic form, 0.195 per cent. in organic combinations. Noel Paton's (Fishery Board for Scotland Report on Salmon, 1898, p. 143), found a mean of only 0.215 per cent., as P_2O_5 , in the muscle of salmon. The phosphorus of Marvis, therefore, is present in considerably larger proportion than in the muscle of pike, and enormously over that of salmon. Of course, the water percentage is very much more in the case of the salmon, where the proportions are given in relation to the fresh muscle, salmon muscle containing about 66 per cent. of moisture, Marvis only 12 per cent. In the dried total solids the total phosphorus of the salmon muscle represents 0.632 per cent., of Marvis 1.68 per cent. as P_2O_5 .

A noteworthy difference also appears between the proportions of inorganic phosphorus shown by Katz's analyses, and those of Marvis; for although the total phosphorus is greater in Marvis, the inorganic moiety is less than in the pike muscle, the organic portion, therefore, is markedly in excess.

While preparing the various data for incorporation into the chapter on Foods, which forms a part of my volume upon digestion in the Contemporary Science Series, and calculating out the food and money values of different common articles of diet. I remember being impressed by the high relative value of dried cod, both for nutrition and as regards value for money paid, when compared with other food stuffs. Though unexpressed in the text the thought occurred to me that any one who should apply this fact towards the preparation of a food-stuff from white fish flesh in a palatable and digestible form would be doing a service to the unhealthy among mankind, and also to many of the normal members of the species. Although ordinary dried white fish is possessed of so high a nutritive value, without doubt it loses much of it owing to its being rather indigestible, when consumed in bulk, perhaps when of uncertain age, however prepared for the table. But the muscular tissues of white fish so often sold at nominal prices, or if harvested too plentifully frequently applied as manure to enrich the soil, if bought and treated on the spot, cheap because the material is cheap, nutritious because its basis is nutritious, digestible and assimilable by reason of the method of preparation employed, offer a most valuable source from which to obtain a rich concentrated supply of food, costing less than the similar preparations from mammalian flesh, and giving as good value in return.

A dry preparation, such as Marvis, consisting in large proportion of the powdered muscular tissues

and fine bones of fresh white fish, together with a small amount of cereal flour, will yield in nutritive value, using König's well-known factors in its determination, of about 353.5 per cent. by weight; while, still following König, if four ounces cost a shilling, the nutritive value in return for every penny spent is represented by 33.38 units.

Dried cod or ling, as usually placed on the market, is so cheap that the value of a pennyworth reaches 732 units, compared with the 432 units of a pennyworth of dried peas, and 49.7 units afforded by lean beef for the same coin, at 10d. the pound.

Thus, lean beef possesses an average nutritive value of 109.5 per cent.; at 10d. a pound each pennyworth bought will equal 49.7 units, at 1s. a pound 41.4 units for each penny, or if in the form of the best rump steak 31.0 units for the same expenditure. Marvis, therefore, per unit of weight is three times more nutritious than lean beef, while if its selling price be taken at 1s. for four ounces its money value as a food is theoretically 70 per cent. of that of cheap beef, a value, however, which is, in practice rendered higher owing to the ease with which the food elements of Marvis can be utilised, and the small proportion of its constituents wasted.

Few of the fluid or semi-fluid meat extracts in the market afford more than 5.35 units in nutritive value per penny spent on them, or six times less than Marvis, while in nutritive value per cent. of their bulk they fail to exceed a proportion higher than one-third of this fish food's theoretical estimate.

Referring again to the book already mentioned, it will be seen from a table on page 393, that 2.7 ounces of dried cod are equivalent in nutritive value to ten ounces of lean beef, and that this dried fish-food has even more nourishment in it than dry powdered meat of which 2.9 ounces equal the value of ten ounces of lean beef, and therefore 2.7 ounces of the dried fish. In addition, it is stated that 2.74 ounces of beef-tea would be required to be taken before the same amount of food-elements, serving to maintain metabolic processes, as in ten ounces of beef, or 2.7 ounces of dried fish would be obtained. Marvis, principally composed of this dried fish in a powdered form, with an approximate nutritive value per unit of 353.5, would only require 3.1 ounces to equal the nourishing elements of ten ounces of lean beef. The 3.1 ounces would cost 9.3 pence, the ten ounces 6.25d.; at 3d. and 0.625d. the ounce respectively. The food value of the one per penny being 33.38, of the other, 49.7.

A number of the food preparations in the market in a fluid or gelatinous form are little more than high-priced solutions of meat extractives, with some power of stimulating the various tissues and organs, especially the heart; but this power is but transient, not sustaining, though it often proves of great value at the time.

The dried food-preparations have of late grown in number, and multiplied exceedingly. The many excellent examples of infants' foods manufactured from cereals, milk, &c., now available can often be usefully employed by adults. The more technical, dried derivatives of proteid digestion typified by somatose, sanose, and their congeners, are even more than the members of the meat extract class, medicinal aids to nutrition, not foods in the proper sense of the word. Indeed, if given in the amounts proper for the total metabolic needs, they frequently cause symptoms more akin to poisoning than to correct alimentation. They again, however, may prove very beneficial under appropriate circumstances.

A word as to beef powders. Theoretically, these are of great nutritive value, easy to digest, and quickly incorporated with the body. Practically, they are of less value, their physical properties, by causing feelings of repulsion often after but a com-

paratively brief experience of them, chiefly, I suppose, because of the strong flavour conferred on them by the rapid meat extractives present, prevent their employment in bulk or for a length of time, while their money value for nutrition is low by reason of the price charged for them.

I have found that made into fish soups, simply or variously strengthened, fish soufflés, custards, and cooked in other ways, Marvis yields most appetising dishes, proves very palatable to patients, and supplies a very valuable addition to our stock of nutritive foods, which is at the same time rich, sustaining, and easily disposed of.

I have been led to write these few lines about this new food because I believe that physicians will find in it a scientific means towards enriching the diet of dyspeptics, and of patients who require to supplement their stores of proteids without digestive embarrassment or induction of nausea.

PROFESSIONAL BEHAVIOUR.

Abstract of an Inaugural Address delivered in St. Vincent's Hospital, Dublin, Oct. 1899.

By R. F. TOBIN, M.R.C.P., F.R.C.S.I.,
Surgeon to the Hospital.

AFTER some introductory remarks, Mr. Tobin said:—If there is one man more than another who has my sympathetic good-will, it is he who, fresh from the schools, full of enthusiasm and first principles, is boldly joining the battle of life. He has yet to learn how little mere enthusiasm will avail him in the struggle, and how many are the exceptions to every rule that has been given him for his guidance. The complexity of life, with its difficulties and interests, is yet a distant cloud about which he does not materially concern himself.

It is of this cloud as it affects the practice of medicine that I purpose speaking to you; and since money may be said to be its electricity, I shall, at the outset, ask you to consider some of the social and economic questions that influence the payment of the profession. First, why should we not have free trade in medicine? Free trade I will define as unrestrained competition—in other words, as regards our relations with one another and our patients, each man for himself, and the Devil take the hindmost. It will take very little consideration to show that it will be an evil day for the public when this rule prevails. For, in the first place, the public have no means of estimating the value of the goods we offer them. On matters medical their ignorance is only equalled by their gullibility. You will not ask me to prove this proposition. Times and times again you have heard your uncles, aunts, and cousins lay down the law on difficult points in physiology, a subject in which, perhaps, you, after much study, have been plucked two or three times. You have seen Sequah, on a prairie horse, ride into public favour; you have known men of intelligence pin their faith and their lives to the teachings of homeopaths and Christian scientists. The difference between the knowledge which the man in the street has of the inside of his watch and his own inside is this—he knows nothing of the inside of his watch; he knows a great deal of his own inside, but all that he knows of the latter is wrong. I may, therefore, take this proposition for granted, and pass to my second, which is equally clear. It is that the patient, who in this matter represents the public, is not in a position, when he is most a patient, to test experimentally the quality of what we offer him.

What I have now to submit to you makes our pecuniary relations with the public unique. To preserve our status and attract suitable men to the profession, we have to put a high price on our services, but (here comes in the difficulty) these services are required as much by the poor as by the rich. This difficulty has been met, and I think properly met, by giving gratuitous service to all whose ability to pay does not reach a certain standard. You must either do this, or you must in some cases take a copper for your services.

The wisdom of our professional ancestors is embodied in the etiquette of the profession, and although they may not have known much of science, they knew a great deal of the world, for conjointly they lived in it a long time. I would therefore advise you in being slow in departing from it. Their usage, as regards fees, as far as I know it, was this—they fixed on what they considered a suitable fee, and they rarely deviated from it, meeting the requirements of those who were not wealthy by gratuitous visits. Against a graduated scale of fees there is much to be said. First, there is the tendency of all patients to gravitate to the lowest scale; secondly, there is the fact, which, however we may explain, your experience will, I believe, confirm, that men educated as doctors do, as a rule, better work for no fee at all than for one disproportioned to the occasion. The graduated fee somehow introduces into the profession an element of trade that is disastrous alike to doctor and to patient.

But the first difficulty that you will meet—you, the youth full of enthusiasm and first principles whom I am addressing—is not the fixation of the amount of your fees, but the earning of any fees at all. Now in this connection the bit of advice I have to give you is, before entering for any event take stock of your own capabilities and qualities. It is well known that to be successful on the turf a horse must not only be a good one, but he must be properly placed. It is better to be first in small events than second in big ones. Therefore, don't enter for a race in which you will be outclassed, or which calls for qualities other than you possess. To work hard is the great pleasure of life, but the work must be congenial and not beyond one's powers. One man will be happiest in the routine life of military service; another in country practice where the strain is rather physical than mental; a third will delight in the keen contest of the metropolis, and in its difficulties find wholesome stimulation. Having selected the line you mean to take, get under weigh at once. It is often fatal to interrupt a habit of work by a lengthened dawdling at home or at sea, or on any road that leads nowhere.

The lazy drifting I have warned you against is usually done by men in search of what they call a vacancy. Now let me tell you there are no vacancies in the medical profession. It abhors a vacuum. You cannot book a place in it. Having selected your theatre you must join the crowd that is waiting, and with a steady pressure hold your own, or perhaps a little more—when a door is opened you must put forth all that's in you, and try and gain a front place. This you may then occupy with complacency, and perhaps after a while turn round and ask, "Who are these fellows that are crushing behind?"

I now propose to say a few words on the difficulties you will find in your way. The first is the necessity of keeping up appearances. We have already seen that the public can gauge in only a very uncertain way our professional skill, and consequently we have to make ourselves loom as large as possible in their eyes. The painter, the musician, the litterateur, even the pure scientist may live and dress very much as he likes—his work goes forth and speak for itself; the shop-keeper has to advertise, but he cries up, as a rule, goods that are the work of other hands than his own; for the medical practitioner is reserved the temptation—I was about to say the necessity—of crying up himself.

You may advertise yourself by your hat, by the play of your facial muscles, by titles, equipages, mansions in fashionable squares, reports of cases, inaugural addresses—in a word, by every action which a man may play. Advertisement with us may be described as a keeping up of appearances, for, of course, it is by appearances the public are mainly guided in their estimation of us. I am not going to run full tilt against advertisement. On the contrary, I hold that a doctor often cannot do better than put his money into his own business—first, by making himself as efficient as possible; secondly, in properly setting forth such efficiency. But, at the same time, I would like to warn you against overstepping the limits outlined by the experience and good sense of the wise men who have gone before us.

Before beginning let me ask you to consider the following points:—First, that it is often contrary to a

man's interests, his pecuniary interest, to be forced too rapidly into practice. It is one thing to make the public think highly of you while you are still behind the scenes, it is another thing to act up to that opinion. The proper practice of the profession is a thing slowly acquired, and although you may have much medical knowledge and skill your reputation in a district may be irrecoverably ruined by your ignorance of the world and its ways.

Secondly, success so attained is not like success honestly won, it leads seldom to happiness. Thirdly, success may not be reached as early as you calculated on, and thus, by the necessity of keeping up appearances that you have made for yourself, you may be landed in monetary difficulties that will darken your whole life.

The second of the difficulties I have referred to arises from the impossibility of steering a bee-line in your dealings with your patients. "Life," it has been said, "is one of compromise, and what we chiefly compromise is the truth."

Now, unhappily in the practice of medicine the truth at times requires careful handling. I have known a patient's pulse intermit one beat on every five on being told the truth, and I have also known a rash use of that virtue cause a doctor's fees to intermit in an even greater degree.

You must see that this constitutes a most dangerous situation. The patient gains by our economy of the truth we also gain, and it is quite possible that what one began in the patient's interest one may almost unwittingly continue in one's own. But lest I should be misunderstood, perhaps I ought here remark that I am not now in any way reflecting on the general veracity of the profession to which we belong. That you and I can hold our heads high is due to the fact that the great majority of the men who have gone before us have steered their way safely through the dangers I am pointing out to you. They were helped in doing so, no doubt, by a cognisance of them. If you value truth, be particularly on your guard on those occasions when you feel yourself called upon to win a patient's confidence. If you do not you will find yourself in time doing, under the cloak of this supposed necessity, what would be amazing things to your present eye. In the first case you are called to you will, perhaps, meet the following situation: You will find your patient in his trouble expecting of you two things—a definite diagnosis and active treatment. I need not point out to you that the latter of these should wait upon the former. Now the lamp of science, much as it has been trimmed of late, does not burn brightly, and as you are anxiously and slowly trying to find your way by its light, the only thing you clearly discern is an expression of doubt on the face of your patient and his friends as to your competence.

In concluding this address I am not sorry at having to omit reference to professional shortcomings, that being the way one usually teaches professional behaviour. For a man not to be envied or imitated is he who takes pleasure in cavilling at the conduct of his neighbours, and constituting himself the unofficial guardian of the honour of the profession. When you feel yourself in that mood ask yourself what would be your true feelings if the rival practitioner you are abusing was seen drunk about the streets. If such news would be, excuse the word, "nuts" for you, it will help you to gauge how much you have really at heart the honour of the profession.

Clinical Records.

TWO CASES OF ABDOMINAL HYSTERECTOMY FOR CHRONIC FIBROID THICKENING OF THE UTERUS.

By CHARLES RTALL, F.R.C.S.,

Surgeon to the Cancer Hospital, Brompton; Surgeon to the Gordon Hospital for Diseases of the Rectum; Surgeon to the Out-patients, London Lock Hospital.

A.B., *æt.* 37, governess, unmarried, was sent to me by Dr. Chas. Heaton on August 14th, 1899, and complained of the following symptoms:—

For the last two years she has suffered from dysmenorrhoea and menorrhagia, and of such a grave nature that she is periodically quite incapacitated from following her vocation. The menorrhagia persisted usually from about seven to ten days, and during that time the amount lost was excessive, with the frequent passage of clots. She also suffered from severe sacral and abdominal pain.

The catamenia has always been copious, and with a considerable amount of pain, but two years ago she suddenly became worse, and since then has been continually under treatment. Drugs, rest, and repeated curetting had been tried but without affording her any relief. She was, therefore, not only willing but most anxious to undergo any surgical treatment which would make her sufficiently well to earn her living.

On examination there was a good deal of tenderness in the hypogastrium, the uterus was found to be enlarged, and reaching just above the pubes, and a small myoma could be distinguished in its anterior wall. The length of the uterine cavity was four inches, and the organ was movable but tender to the touch.

Hysterectomy was recommended, and met with the patient's approval.

Operation, September 5th, 1899.—On opening the abdomen the enlarged organ was drawn out of the wound, and on examination proved to be very hard and paler than normal, which was due to an excess of fibrous tissue, which could be distinctly seen beneath its peritoneal investment. Hysterectomy was performed, leaving a cervical stump, and the operation was finished in the ordinary way.

The patient made an uneventful recovery.

E.B., *æt.* 50, married, was sent to me by Dr. R.H. King, and admitted to the Cancer Hospital on Sept. 11, 1899, and was said to be suffering from a uterine tumour.

Two years ago she had a miscarriage, and since then she has not been well. She complains of constant sacral pain and pain of a throbbing nature, which she refers to the rectum, and which is worse on defecation. There is a thick vaginal discharge, usually yellow in colour, but occasionally brown, and sometimes foetid. Menorrhagia of a severe nature is a great source of trouble to her; it lasts usually a week, and the loss is very excessive. Drugs, rest, and repeated curetting had also been tried in this case, and with a negative result.

On examination the uterus was found to be retroflexed and fixed in Douglas' pouch, and the fundus enlarged to about the size of a cricket ball, and apparently the site of a small myoma. The os uteri was patulous, but no tumour could be felt within.

Operation, September 12th, 1899.—On opening the abdomen the uterus was found firmly adherent in the pouch of Douglas from which it was liberated, and also from some adhesions of the sigmoid. On exposing it to view no tumour could be detected, and the enlargement was the result of a process of fibroid thickening which was found in the previous case. Hysterectomy was performed in a way similar to the other case. The patient made an uneventful recovery.

Remarks.—These two cases were brought forward to show what the operator considered the proper treatment for trouble of such a nature. The patients were chronic sufferers, and drugs and repeated curetting had been tried to relieve them but in vain, and needless to say the patients were therefore only too anxious to have anything done that would restore them to health. The disease was a fairly common one, was inflammatory in origin, and was frequently traced to septic endometritis. The pathology of the affection consisted in a thickening of the uterine wall by fibrous tissue and a partial disappearance of the muscle elements. A marked thickening of the endometrium was also a feature of the disease. He considered hysterectomy as the proper treatment for these two cases and as the only means that would effectually restore the patients to health.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, OCTOBER 12TH, 1896.

The President, DR. MACNAUGHTON-JONES, in the chair.

SPECIMENS.

DR. MACNAUGHTON-JONES showed:—

TWO UTERI REMOVED BY VAGINAL HYSTERECTOMY FOR INTRACTABLE PROLAPSE.

CASE 1.—The patient was *æt.* 38, 5-para. The uterus, with a fibroid in the fundus, was removed for procidentia of 15 years' standing. The bladder was firmly adherent to within half an inch of the os uteri, and there was extensive ulceration of the cervix. The operation was a difficult one. The patient made an excellent recovery and is now more than a year after the operation, in perfect health and comfort.

CASE 2.—The uterus was removed recently from a patient, *æt.* 74, for a large procidentia of over 25 years' standing. There was disease of the cervical endometrium and attendant ulceration of the sac externally. She had had both pain and great discomfort. Both bladder and rectum were in the sac. The former viscus was firmly adherent to the entire sac-wall, reaching to the os uteri. Hysterectomy was performed, the adhesions were slowly cleared, and the ureters, being exposed, were avoided. The rectum had also to be freed posteriorly from the sac-wall. The vagina was subsequently curtailed by circular incisions, the bladder and bowel were returned into the pelvis, and the wound closed by the union of the peritoneal edges and adaptation of the vaginal flaps. The patient was making an excellent recovery.

FIBRO-MYOMA REMOVED BY SUPRA-VAGINAL HYSTERECTOMY.

This was a large, stony, hard fibroid tumour that filled the pelvis and reached to the umbilicus. The difficulty in removing consisted in the pelvic adhesions, reaching posteriorly to a level with the coccyx. The patient was anemic, emaciated, and extremely nervous. Myohysterectomy was performed. The delivery of the tumour was a matter of considerable difficulty, but was eventually safely accomplished, and the patient made a perfectly satisfactory recovery.

DR. HEYWOOD SMITH observed that in one of the first two cases the uterus was myomatous, and so could not be considered as a case simply of prolapse; and he thought that the term should be restricted to cases of prolapse pure and simple. For cases of simple prolapse he thought that ventrofixation was better than hysterectomy. In the second case it appeared to him that it would have been sufficient to amputate the cervix.

DR. MANSELL-MOULIN recalled the fact that not long ago a case was reported at the Society in which hysterectomy was done for prolapse, and the procedure was somewhat severely criticised; but the question of justifiability need not now be dwelt upon. As to method, there had been suggested a plan which he thought would have done well in these cases, *viz.*, extraperitoneal hysterectomy by means of the *serre-neud*. This had the advantage of conserving the pelvic floor; and in Dr. Macnaughton Jones' cases would have avoided the difficulties attendant on the operation. He had adopted this plan in several cases with very good results.

MR. FURNEAUX JORDAN (Birmingham) stated that he had done vaginal hysterectomy twice for prolapse, which could not be relieved by pessaries. Both operations were done about ten months ago; and both patients had since returned to hospital with inversion of the vaginal walls, for which he had to perform plastic operations. Consequently he did not feel inclined to try this treatment again. He hoped that Dr. Macnaughton-Jones' results would be more satisfactory. The question arose, What were they to do in such cases? In the case of the first specimen shown it appeared to him that the best plan would have been removal of the appendages and ventrofixation; but he would not advocate ventrofixation in a patient who might yet bear children. As to the most satisfactory

treatment of Dr. Macnaughton-Jones' second case, he thought it was a very difficult question to decide.

MR. BOWREMAN JESSETT said that in the second case he would have preferred ventrofixation because of the difficulty in getting the uterus away; and now that the uterus was away, the patient had lost some of the support of her pelvic floor, and prolapse of the rectum or vagina might follow. Such risks would be avoided by ventrofixation.

MR. CHARLES RYALL remarked that prolapse of the vaginal walls was very rare after vaginal hysterectomy for tumours; but it was rather more common after hysterectomy for prolapse. He did not agree with Mr. Furneaux Jordan's view that the appendages should have been removed in the first case; in his opinion the best plan would have been amputation of the cervix and ventrofixation.

DR. MACNAUGHTON-JONES, in reply, said that one of the chief reasons for not doing a simple hysterectomy in the first case was the fact that the cervix was unhealthy. He might have amputated the cervix, but this would have had the disadvantage of leaving an unhealthy body of the uterus, which would probably have resulted in a return of the patient's trouble to its original condition. With regard to the second case, he hesitated between ventrofixation and hysterectomy, but decided on the latter as likely to be the less severe. If the bladder had not been so adherent it would have been a very simple operation, but he was deceived as to the bladder attachments. Nevertheless, he did not think that the patient would suffer later on from prolapse, either of the rectum or of the bladder.

MR. CHARLES RYALL showed uteri with fibroid thickening removed by abdominal hysterectomy, which will be found under the heading of "Clinical Records."

MR. BOWREMAN JESSETT said that these cases raised two or three questions:—(a) Was it desirable to do any serious operation for this condition? (b) If so, should the uterus be removed or the appendages? (c) If the uterus required removal would not vaginal hysterectomy be better than abdominal? (a) With regard to the first point he had himself adopted with good results in such cases a milder plan of treatment—*viz.*, curettage followed by burning out the endometrium with strong nitric acid, plugging with iodoform gauze and washing out with bicarbonate of soda to counteract excess of acid. He would always try this plan before resorting to hysterectomy. (b) Removal of the appendages was a less severe procedure than hysterectomy, and would probably be followed by cessation of hæmorrhage. On the other hand he recognised that after such treatment the nervous system of the patient might be affected. (c) He would like to know why Mr. Ryall did not operate by the vagina in preference to the abdominal route.

DR. WALKER SMYTHE asked whether, if the uterus had been left in these cases, any great harm would have resulted to the patient. Not long ago, he had a case of a woman with a myomatous uterus larger than those shown by Mr. Ryall; she was anxious to be operated on, but he persuaded her to wait; and the fibroid had now got decidedly smaller. It did not appear to him that there was any great necessity for the removal of the uterus in such cases.

THE PRESIDENT said that the question in these cases had been admirably summarised by Mr. Jessett. The most common cause of this condition was hyperplasia of the connective tissue of the uterus followed by formation of fibroid tissue therein. He should not himself remove the uterus for such a condition, unless there were also some indication of malignant changes; he concurred in what Mr. Jessett had said about removal of the appendages, but this was the course which he would have been disposed to adopt in the present case. He would recall to Mr. Jessett's recollections the fact that it was over 30 years since Dr. Lombe Atthill advocated the use of strong nitric acid for this very condition. This was the only treatment which he himself carried out for many years, until curetting became more frequent, and he doubted whether they had gained much by giving up the use of nitric acid in favour of curetting in every case, in view of the arrest of hæmorrhage

and the reduction in the size of the uterus which the nitric acid brought about. He had heard the treatment adversely criticised, but this was because it was not carried out in the manner prescribed by Lombe Atthill.

Mr. RYALL, in reply, said that he adopted the abdominal route because he preferred it for two reasons: in the first place it enabled them to deal much more readily with adhesions; and in the second place they could see much better what they were doing. He had not used nitric acid in these cases because he did not regard the condition as a disease of the endometrium, but as a fibroid thickening of the uterine wall. He did not wait before operating, as Dr. Walker Symthe suggested, because the patients were anxious to be put into a condition in which they could earn their living; and from this they were debarred by their complaint. Everything had been previously tried, in the way of palliative measures, but without result. As regards removal of the appendages, he thought it was always better to remove the diseased organ and leave the healthy ones; and hence he considered it preferable in such cases to remove the uterus.

Mr. J. FURNEAUX JORDAN (Birmingham) read a paper "On the after results of operations for the removal of the uterus and appendages," which we hope to publish in full, with the discussion thereon in our next.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, October 22nd, 1899

ESSENTIAL HÆMATURIA.

At the Fourth Session of the French Association of Urology, M. M. Malherbe and Leguen read a very interesting report on Essential Hæmaturia.

Up to late years, the papers read on hæmaturia were divided into two classes, essential and symptomatic. This latter, the more frequent and the better known, depended on some well-defined cause; while the former seemed independent of any lesion of the urinary apparatus and appears to constitute simultaneously symptom and malady. To distinguish that affection from the other the term, "essential hæmaturia" was invented. But could hæmaturia really exist independently of a lesion of the renal organ or of a more or less established disease? Such was the question the authors proposed to treat, after passing in review the different causes of symptomatic hæmaturia, which were of two orders—general and local.

Infectious Maladies—Hæmaturia was frequently observed in the course of infectious maladies, and more especially in those cases where the fever ran high; it constituted, generally the ultimate period of the affection and rendered the prognosis very grave. The blood could come from any position of the urinary tract, but it was probable that the seat of the hæmorrhage was the kidney. Where the cause was local the hæmaturia could derive from the urethra, the prostate, the bladder, the ureter, or the kidney. Abundant hæmaturia had its cause exclusively in the bladder or the kidney, and was provoked habitually by calculi, tuberculosis, neoplasms, or retention, more rarely by traumatism, inflammation (nephritis) or parasites (hot climates). Such were the principal causes of hæmaturia resulting from a manifest lesion of urinary apparatus and notably of the renal organ. Whether it were a case of traumatism (calculus), of inflammation (nephritis), or of a neoplasm there was a factor which

in the pathological physiology of hæmaturia intervened at each stage; it was *congestion*. Congestion played in urinary pathology a very effective rôle. M. Guyon had frequently insisted on that point. It was it which determined frequently the hæmaturia modifying the clinical aspect of the symptom, and troubling the practitioner by a disconcerting paradox.

Essential Hæmaturia.—After having passed in review the great causes of symptomatic hæmaturia, the authors treated of essential hæmaturia, which, in its clinical characters they said did not present any particular sign. It was frequently very abundant, so as to produce anæmia, and was rebellious to all treatment. What was in reality essential hæmaturia? In pathology every phenomenon had a cause, and although the cause could not be determined, it did not follow that it did not exist. When hæmaturia occurred it should in some way have its *raison d'être*. If it was not found it was because the insignificant lesion had passed unperceived, and that lesion was almost in every case to be found in the kidney, consequently *essential hæmaturia did not exist in fact*.

The predominating character of pseudo-essential hæmaturia was that it did not resemble any of the forms habitual to that of calculus, neoplasm, or tubercles. Abundant and continual, it was not influenced by rest or motion, and appeared at first as renal hæmaturia, but other symptoms were sought for in vain. The treatment of that kind of hæmaturia depended on the cause, but the cause was unknown; therefore an exploratory incision became necessary to complete an imperfect diagnosis. It was only in the course of that incision that nephrotomy or nephrectomy could be best decided upon.

TOTAL ABDOMINAL HYSTERECTOMY.

At the first meeting of the Surgical Congress held in Paris last week the subject of abdominal hysterectomy was discussed. M. Ricard, in a review of the question, said that abdominal hysterectomy for fibroma was practised there last year according to very different methods, but it might be said that there were only in reality two principle methods according as the operation was done with or without previous ligature of the arteries. The latter method of operating belonged exclusively to M. Doyen, who removed fibroma from the abdomen without paying any attention to possible hæmorrhage.

Ligature of the vessels, on the other hand, had the advantage of being applicable to every kind of tumour. As to the operation itself, surgeons were divided as to the method. Some maintained that total hysterectomy gave most successful results, while others, and the speaker was one of them, considered that a great point was gained in not opening the vagina and leaving a stump of the os behind. To this operation they gave the name of sub-total supra-vaginal hysterectomy. The advantages of the method were considerable; the operation was more quickly and more easily done, less hæmorrhage took place, and antisepsy was easier to effect. The mortality was also one-half less than that of total hysterectomy.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, October 21st, 1899.

TUBERCULIN SOAP.

(Continued from page 400.)

ANOTHER important advantage of treatment by

tuberculin soap was the painlessness, especially as contrasted with salicylic creosote gauze plaster and caustic paste. There were some very sensitive lupus patients, in whom the first parts of the treatment were, on account of their sensitiveness, very prolonged, and for whom an entirely painless application was very desirable. There were also regions of the body that in all patients were exceedingly sensitive; among these he reckoned the internal ear. In these parts the acquisition of the tuberculin soap was a true gain.

The new preparation had proved its value in those parts where, under certain circumstances, no application could be made, the mucous passages. For here gauze, plasters, caustic vapours, green salve, and caustic paste were very difficult to apply. For the auditory passages, the nasal openings, the eyelids, lips, and angles of the mouth the tuberculin soap was better than the other remedies during the first stage.

It was a natural step to extend this treatment that had answered for the mucous entrances to lupus of the mucous surfaces, first to the mucous surface over the gums, the cheek, the palate, and nasal cavities. The daily application was less painful than in the case of other remedies. If other applications were not rendered altogether unnecessary, the field for their employment was much restricted. In the mucous surfaces the resorption of remedies was much easier than in the external skin, and under the simultaneous action of the soap was still further facilitated. Here, as in the skin, the most striking results were obtained where a fibrous new growth was present, as in snout-like projections of the lips, narrowing of the mouth-opening, and the nasal entrance.

Finally, he would mention as suitable for tuberculin soap treatment those cases where healing was nigh at hand, where a small remnant of lupus remained, but which resisted treatment. These were mostly small circumscribed reddenings, with scale formation, and which diascopically did not allow any distinct lupus centres to be recognised. In many cases there was only a post-lupus eczema-like skin affection, which healed rapidly under zinc sulphate paste. In other cases these punctiform remnants were present. Here, it was more agreeable to the patient, and instructive to the attendant, to make use of the tuberculin soap. A positive reaction, as well as a rapid healing, both pronounced in favour of the tuberculous nature of the affection. But occasionally a distinct brown lupus centre first appeared, which could be quickly needled out.

No surprising new fact was brought to light by this treatment. He had, however, gathered the impression, in seven of the cases treated, that the tuberculin soap had achieved more under certain circumstances than a simple tuberculin vehicle should achieve, and than he had expected. When following the analogy of the tuberculin injection treatment, he had expected an unusually large number of lupus centres for needling out; he was surprised to find that the number was unusually small. A case of symmetrical lupus of the nose and cheek showed this fact in a striking manner. One side was treated with green salve, the other with tuberculin soap. Should it be shown by further observation that tuberculin soap did more than tuberculin itself in the treatment of lupus, it would not be surprising, as the potash soap, forced in along with the tuberculin, doubtless had a destructive influ-

ence on the tubercle bacillus, and the more so as the tuberculin at the same time removed the reaction wall set up by it. In that case they had indeed in the combination of tuberculin and potash soap a happily selected antilupous remedy.

Although at first tuberculin soap was only intended for tuberculous affections of the skin, after its success the limits of its application were naturally extended. That it exerted a rapid and favourable action in two cases of scrofuloderma he only mentioned as something that might be expected.

It was more interesting to him to use it in various leprosy affections. Up to the present he had used it in six cases of leprosy, with the noticeable result that a direct therapeutical result was obtained by subcutaneous infiltration in neuroleprosy cases only (2), and not in the cutis lepromata (4 cases). In the two neuroleprosy cases by the due application of the tuberculin soap alone he had obtained a striking improvement, until the whole spur had gradually taken on the appearance of a thin white atrophied skin free from leprosy. In cutis lepromata it only hastened complete resorption after previous destruction of the surface with caustic paste; but for this subordinate rôle we possessed so many other good remedies, that the tuberculin soap need not be considered. A good result was, however, obtained in the fibromata and cheloids of lepromata, that had been burned with caustics.

After lepra the behaviour of tuberculin soap in the treatment of ulerythema Antrifugum (improperly so-called lupus erythematosus) interested him. Up to the present he only had the opportunity of employing it in two cases. The result was not so favourable as in lupus, a severe acute inflammation took place with swelling, and to some extent profuse serous exudation, but after its disappearance the ulerythema showed itself no better.

The remarkable effect of tuberculin soap on fibrous sclerotic lupus, and the healing of cauterised lepromata led the speaker to use it on the firm sclerotic patches of tertiary syphilitic origin. Here also the result corresponded to the expectation (three cases). One was a case of extensive gummatous swelling near the knee, in a woman who could not bear iodide, and on whom mercury, long continued, had no effect.

The local application of mercurial gauze plaster had a decidedly good effect, but a rapid and permanent cure was only obtained when this treatment was combined with the tuberculin soap applied twice daily. The extremely firm tissue mass melted away, or became absorbed. Particularly striking was the effect of the tuberculin soap on the firm sclerotic cords passing through the skin, and attached to the fascia and periosteum. In another case of obstinate periosteal gumma of the tibia, sudden softening and rapid absorption took place.

After those experiences, he had recently tried the tuberculin soap on cicatricial cheloid (two cases; burns and surgical operations). The result was a slow, but an unmistakable improvement. First of all softening of the cords took place, and then resorption.

He had also tried it in lichen and glandular tumours, but without special result; but he had never seen any harm result, even when the 20 per cent. strength had been used for months. He could, therefore, recommend the tuberculin soap to specialists and practitioners for the dermatoses mentioned as a form of tuberculin as agreeable as it was active.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, October 21st, 1899.

ACUTE LYMPHÆMIA.

At the Medical Club, Pineles recorded a case of lymphæmia of some interest owing to the great age (73) of the patient: she had never been ill and confined to bed at any time before, and could do her house-work actively up to three months ago, when she was suddenly attacked with headache and high fever. She recovered in a week or fourteen days, but was not strong enough for her domestic duties, and finally had to return to bed with pain in head, breast, &c., when she was removed to hospital complaining also of a "discharge of matter from her chest," dulness in the head and general confusion. On her reception the muscles were observed to be lax, and the adipose tissue fairly retained, with pain over sternum when pressed, as well as in both legs. Temperature 37.2 degs., pulse 100. The radial artery had a serpentine movement: vesicular sounds in upper part of lung; cardiac sounds dull; liver enlarged downwards with rounded edges. The spleen extended three fingers' length below the ribs, and was not painful on pressure. The glands of the throat, axilla, and groin were all enlarged. The flexor side of the forearms had small hæmorrhages ranging from the size of a linseed to a sixpence, gums swollen and bleeding, as well as lower surface of the tongue, fundus of the eye normal, urine much nucleo-albumin, but no serum-albumin.

The next day consciousness became dulled with tetanic spasms in both arms. On the lower extremities several small hæmorrhages; highest temperature, 38.7 degs. After this the weakness and delirium increased, and she died nineteen days later.

The enlargement of the liver and spleen with hæmorrhage from the teeth and skin pointed to leucæmia. Examination of the blood gave 3,550,000 erythrocytes and 550,000 leucocytes in the millimetre of blood. The proportion of white to red being 1 to 6½. The red blood corpuscles had nothing special in size or form; rouleaux in small masses, and the fibrin slightly netted. White corpuscles somewhat small; preparations with eosin hæmatoxylin and Ehrlich's tri-acid mixture gave 92 per cent. of large leucocytes ungranulated and small lymphocytes, 3.8 per cent. common neutrophile polynuclear leucocytes, 0.0 per cent. polynuclear eosinophile cells; poikilocytosis was not present, nor were there any nucleated red cells. When coloured with fuschine none of the cells showed basophile granulation. The post-mortem revealed skin white, no œdema, lymph glands of neck enlarged, as well as those of axilla and groin, but nowhere adherent to the skin. In the left pleura slight fibrinous deposits, lungs full of blood, both upper lobes lobular pneumonia. Pericardium slight fibrinous deposit, heart enlarged containing blood of light colour. Liver one and half times normal size, of a yellow-brown colour, friable, numerous white spots with interlobular division. The spleen was eight times its normal size, and had a reddish grey colour, in section and lymphatic glands, white patches. The kidneys were bleached and soft; retro-peritoneal glands swollen while the marrow of the bones was red and almost free of fat. Microscopically the lymph glands

were hyperplastic but normal in structure. The lymphoid cells had nothing peculiar, and nowhere were there any abnormal conditions except a deposit of lymphocytes from the blood. A similar condition was present in the spleen. The most prominent changes were in the bone marrow, which was largely composed of lymphatic tissue, with great and small granulated lymphocytes in the form of nests. The common granulated polynuclear leucocytes and the eosinophile cells were quite separate. It was therefore concluded that the structure of the marrow and the lymphatic apparatus of the blood were the cause of the disease which might be termed acute lymphæmia. It is usual to designate chronic leucæmia as myelogenic leucæmia when the myeloid changes of the lymphatic glands and blood are at fault, while lymphæmia, according to Muller, is confined to the hæmatic organs.

Etiologically, several hypotheses are offered. (a) Infection, which is inferred from the rapid prostration, and in this case supposed to be latent. This was absolutely negated by injecting two guinea pigs with 10 c.c. of the patient's blood, when no changes were produced in the animals' blood. The same negative results followed inoculation. (b) The second hypothesis in acute lymphæmia is attributed to the polynuclear leucocytes in the blood being greatly diminished, which is the more probable explanation in this case.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

ABSCCESS IN CONNECTION WITH APPENDICITIS.—Mr. ANDERSON operated on a girl, æt. 18, suffering from pain in the right iliac fossa and fever. On examination, fulness with muscular tension was found over the position of the cæcum and along the line of Poupart's ligament as far as the internal inguinal ring. The patient had had no intestinal symptoms, but a vaginal discharge had set in on the day preceding the operation. A diagnosis of appendicitis was made with some reservation, as the symptoms might have pointed to salpingitis. An incision was made about 2½ ins. internal to the anterior superior spine and extending downwards along the upper half of Poupart's ligament and upwards for a distance of 1½ ins. On reaching the subperitoneal tissue a small abscess was found close to the internal abdominal ring apparently not communicating with the peritoneal cavity. The pus was evacuated and the cavity temporarily plugged with cyanide gauze. The peritoneal cavity was then opened. The appendix was found surrounded by inflammatory adhesions running downwards and inwards, the tip becoming adherent to the parietal peritoneum at the internal inguinal ring at the point opposite to which the subperitoneal abscess had formed. No pus was found in the peritoneal cavity. The appendix was removed in the usual manner. It was found to be in a state of catarrhal inflammation, and contained a small faecal concretion. The peritoneal wound was carefully sutured, the lower end of the incision through the skin and muscles being left open for drainage of the abscess cavity. Mr. Anderson remarked that the symptoms were obscure, and that it was difficult to make a positive diagnosis between appendicitis and salpingitis. The condition revealed was peculiar in that the diseased appendix which ran in an unusual direction had led to

suppuration in the subperitoneal tissue, while the peritoneal cavity showed no sign of pus, although considerable inflammation had been going on around the affected structure.

A week after the operation the patient was going on satisfactorily.

WESTMINSTER HOSPITAL.

SUPRA-CONDYLOID (STOKES-GRIITTI) AMPUTATION OF THE THIGH FOR MYELOID SARCOMA OF THE TIBIA.—Mr. WILLIAM TURNER operated on a man, æt. about 32, who had a large swelling in the upper end of his right tibia, which extended down the bone for at least six inches; its surface was irregular, soft in parts and hard in others, and on the outer side extended nearly to the head of the fibula, where it was soft and distinctly pulsating; the skin was unaffected, and there was no cedema, but there was marked local heat in the region of the swelling; the temperature, however, was normal, the knee-joint was unaffected, and movements were fairly good, though extension of the joint produced pain; the muscles of the leg and thigh were very wasted; the glands in the groin were unaffected. The patient stated that he had had pain for nearly ten months; that he recently had an injury, after which he noticed a swelling; the original aching pain in his leg had at first been ascribed to varicose veins, but although the subcutaneous veins all over the swelling were enlarged at the time of admission, there was no definite disease of the veins. During the week following admission the swelling had increased about an inch in circumference. A photograph by the X-rays taken of the limb showed that the upper half of the tibia was affected by a mass not so opaque as the ordinary bone. About 2 ins. from the head of the tibia there appeared to be a fracture of the compact portion of the bone as indicated by an irregular clear break in the shadow. As the diagnosis was clearly that of myeloid sarcoma, and the extent of the disease far too great to allow of excision of the growth, amputation was decided upon. After the administration of an anæsthetic, a tourniquet was applied about the middle of the thigh, and, the usual antiseptic precautions being taken, a horse-shoe shaped incision was made from the posterior part of the internal condyle of the femur downwards, and then across the head of the tibia just above its tubercle and up on the outer side to a corresponding situation at the external condyle; the skin and subcutaneous tissues were dissected up in this flap to the upper border of the patella; the posterior flap was made by joining the ends of the first incisions by a straight cut at the centre of the popliteal space, this flap was dissected up about $\frac{1}{2}$ of an inch in all. The ligamentum patellæ was then divided close to the head of the tibia, and the knee-joint opened at the same spot. The ligaments and tendons on the inner side were next divided, and the same procedure adopted on the other side; the knee-joint being then flexed the crucial ligaments were next cut across, and all the structures in the popliteal space finally divided by one sweep of the knife, care being taken not to injure the posterior flap. The patella was then held up, and the condyles of the femur cleared for the saw, which was put on just at the union of the condyles, and the shaft, i.e., just above the position of the adductor tubercle. The sides of the

patella were then cleared, and the ligamentum patellæ being firmly held upwards by a pair of lion forceps, the cartilaginous portion of the bone was removed by a fine saw. The patella was then fitted against the sawn ends of the femur, to which it adapted itself perfectly, and was fixed in its new position by means of two stout pieces of kangaroo tendon passed through the patella and through the femur twice on either side in the same manner as a Halstead's stitch. The part of the ligamentum patellæ that had been held in the forceps was removed. The large vessels were then picked up, and the popliteal nerves cut short, the tourniquet was then removed, and all bleeding arrested. The wound was stitched up by means of three fairly thick silk sutures, and then a continuous fine silk suture brought the edges of the skin into apposition; a drainage tube was inserted in the centre of the incision to drain what remained of the popliteal space, and a dressing applied. Mr. Turner said that the reasons for which he chose this operation in preference to any other were: that a Stephen's Smith amputation through the knee-joint was in this instance impossible as the growth was so superficial, and had so evidently penetrated the periosteum of the tibia that the flaps required could not have been made without going through sarcomatous tissue. There was also the danger that the knee-joint itself might be involved (but this proved at the operation not to be the case), the other amputations through the condyles, namely, Carden's or Lister's modification of it have, he pointed out, the disadvantage that the end of the stump is much larger than the rest of the femur, and the bone is only covered by the skin flap, and it is generally stated that patients are often unable to bear weight on the end of the stump; the disadvantage of Gritti's amputation is that the patella does not fit on to the lower end of the femur, and in the majority of cases tilts forward, and so bony union does not occur between these bones. Stoke's modification of this operation consists in the removal of the condyles, so that the patella when affixed to the end of the femur forms a complete covering to the end of the bone, and on account of this slight decrease in length of the femur, the liability to the shifting is reduced to a minimum if the bone is firmly stitched in position. The scar is posterior, and well out of the way of all pressure. The only disadvantage he pointed out to the operation consisted in the fact of the surgeon having to leave the sub-crural pouch of synovial membrane behind which might give rise to some trouble if it became inflamed; he also added that if by any chance antiseptic precautions were not complete in such an operation this pouch would be a source of great difficulty to the surgeon and danger to the patient.

It is satisfactory to state that the patient was discharged convalescent three weeks after the operation, although he had rather severe oozing from the wound for the first 24 hours, this was controlled by pressure and elevation of the limb. The drain tube had to be kept in longer than usual owing to the space it was draining being filled with blood clot. During the second week the patient was able to have the end of the stump knocked with the flat of the hand without feeling any pain.

WEDNESDAY, OCTOBER 25, 1899.

THE SCIENCE AND ART OF EDUCATION.

"DOCTRINA vim promovet insitam." In these four words the great principle of education is stated; doctrina, or teaching; promovet, promotes or develops vim insitam, the inherent energies or qualities of the pupil. And if we make Doctrina a predicate, as probably Horace, philosopher as well as poet, would have allowed, we should say that any system of education that does not follow this principle is not doctrina at all, but is dangerous and injurious in its exercise. If we limit ourselves now to the consideration of how to carry out this principle in respect to the education of those who intend to devote themselves to the profession of Medicine and Surgery, we may assist both the teachers of the young and their parents, in the development of the vim insitam. We should advise both to examine carefully whether this exists, and is of such a nature as probably to repay the culture bestowed upon it, when the object in view is the practice of medicine. What are the qualities which fit a man to be a good doctor? They differ much from those required for a good lawyer or a good man of business. We won't say for a good clergyman, for in the character of such a man as the late Bishop of Bloemfontein we see the doctor and the clergyman may be combined in one person. The moral and mental and physical qualities require each of them to be carefully studied before the system of teaching is commenced. A good hand and a good eye, and a firm but gentle nature, are necessary for the profession of medicine. Those peculiar mental qualities which distinguish the classical scholar from the mathematical, are neither of them of special value to the physician or surgeon. In the study of such a complex organism as the human body but little assistance is gained from

the study of the language and literature of the past; and if we look back to the lives of those who have been distinguished in the profession we find no evidence of great mathematical power. Indeed, where it did exist, as in such men as Thomas Young, Woollaston, and a few more, the tendency they showed was to leave the science and art of medicine for the more exact and satisfactory subjects included in the general term mathematics, or to some branch of exact science. The question of education is one really in which the Profession ought to take a great interest, for none are so well qualified to analyse the vim insitam of the young as those that have had to treat them, and their parents, professionally. There is an idea which to some, indeed, to many, seems very clear, and that is, that in education the chief point to keep in view is the "training of the mind." At most of our schools it is considered "bad form" for a boy to say what he is going to be, or for the masters to have anything to do with this. Even at our universities the same spirit prevails, and the Doctrina mentis in college is conducted very much on the same principles as the doctrina Corporis on the rivers. A young fellow when in training has no idea of ever making anything in the way of earning a living from it. Thus the training of the mind and the body are separated, and to some extent are opposed to one another; at least, they used to be so more than during this last half century. But when we ask what is meant by training the mind, we are generally met with a placid and somewhat contemptuous refusal to go into such a matter. To ask such a question is regarded as an evidence of the greatest ignorance. One naturally feels disposed when the expression is used to ask what's to be done if there isn't any mind to train, so far at least as Greek, Latin, and mathematics are concerned. There is no use in arguing this question with the mind-trainer, and the best plan is to leave him alone. It is very important for us to consider to what extent knowledge of various kinds is learnt from books and words. Classics and mathematics can be learnt from them; but when we come to deal with the teaching of any arts where technical skill is required it is a very different matter. It is not by words or books that music, painting, engineering, surgery in all its branches, and, lastly, medicine, will be learnt. On what "vim insitam" will the "doctrina" of any such sciences as chemistry, geology, or astronomy depend except on the organ of sight. For a classical master to treat the subjects generally classed under the term natural science with indifference, is to disqualify him completely from directing the education of those whose vis insita justifies them to excel in the study of science. This is the point to which great attention ought to be given; and it is chiefly, we believe, because our American cousins have not neglected it that we find they have been making progress in those improvements which attract the attention of visitors from this side of the Atlantic. In the interests of the

young, who will have to support themselves by their work and have no capital to fall back upon, the profession ought to exert itself in providing for better education than is at present afforded in the great middle class of this country.

THE CONTROL OF NIGHT SHELTERS.

DURING recent years the attention of sanitarians has been repeatedly drawn to the presence of a new danger that has arisen in the midst of the community, namely, the establishment of charitable or pseudo-charitable night shelters for the vagrant and destitute poor. The absolute necessity of stringent control in the case of the common lodging-houses has been recognised by the legislature, which has provided, in the Public Health Act of 1875, for the registration and the enforcement of a good structural and sanitary standard by the local sanitary authorities. In the new class of shelters, founded on professedly philanthropic motives, a charge ranging from one penny to sixpence per night is almost invariably made in return for the accommodation afforded. That the majority of these institutions yield a substantial margin of profit appears to be a reasonable conclusion when we take into consideration the rents and working expenses that can be estimated with a tolerable degree of accuracy. Besides, if the common lodging-houses can carry on their business at a profit in spite of the cost of compulsory conditions of tenure, it surely stands to reason that their pseudo-charitable competitors, who have no limit and no costly sanitary standards, will also show a profit side to their ledger. The fact is that some of the Salvation and other shelters are common lodging-houses in all but name. They have kitchens and general rooms for the use of all comers, who pay in some instances a larger sum, sixpence to wit, than that required by the common lodging-house keeper. On the other hand the pseudo-charitable shelters are practically outside sanitary control. They are open to the visits of the Medical Officer of Health only in the day-time, that is to say, when the places are empty. At night, official admission can be gained only as a favour, or by virtue of a magistrate's warrant when a nuisance is suspected to exist. From these statements it will be clear that the "shelters" are free to do as much or as little as they like by way of absolute sanitation as regards their inmates, or relative sanitation so far as the outside community is concerned. There is abundant evidence that serious abuses exist in these institutions. In July, 1895, a conviction was obtained by the Medical Officer of St. George's, Southwark, for gross overcrowding in a Salvation shelter situated in his district. In the last serious epidemic of small-pox in London, no less than thirty-nine cases of infection were traced to night refuges belonging to the same body. Lastly, the London County Council has issued a report which discloses all kinds of structural and administrative shortcomings in the shelters of the Metropolis. The County Council secured a promise in April, 1898,

from the Local Government Board, that a Bill for the consolidation and amendment of the Common Lodging-houses Acts would be prepared forthwith. However, the Government that has been strong enough to pass the revolutionary and retrograde measure abolishing compulsory vaccination, has apparently not found sufficient energy or leisure to bring forward an urgent and comparatively simple reform. The reason is possibly political: the anti-vaccinators are a small but clamorous and united body; the medical profession is without any organisation or voice capable of affecting Parliamentary elections. The Salvationists and other bodies that found the shelters have, as a rule, perfect union and far-reaching social influence. The day of reckoning, however, cannot be far distant, for the existence of these officially-controlled collections of vagrants in the midst of our great centres of population cannot be much longer tolerated. Unfortunately, the law dealing with them is uncertain. The London County Council recently summoned for failure to register as common lodging houses one each of the Rowton and the Victoria Homes and a Salvation Army shelter as test cases. In each instance the application was dismissed with costs. The magistrate decided that the Rowton Home was not a common lodging-house, and that both the Victoria Home and the Salvation Army premises were charitable institutions. While he agreed that there was nothing in the statute to confine its remedial action to commercial undertakings, he felt bound to decide the case on the terms of *Booth v. Ferrett*, in which it had been laid down that a common lodging-house must be kept for purposes of gain. It is satisfactory to know that the County Council will carry two of the cases to the High Courts. As regards the Victoria Home the magistrate was satisfied that although a profit was made, the home was not kept by a person or persons for the purposes of gain. It seems to us that before these extraordinary paradoxes are accepted by the public they have a right to demand authenticated balance sheets from all the bodies who profess themselves to be philanthropists, but who, nevertheless, made profits out of the pence of the most destitute class of the community. Well may the common lodging house-keepers call out against the partiality of the law towards his pseudo-philanthropic rival. In the interests of the public and of systematic prevention it is to be hoped that this question of the control of night shelters or refuges will be speedily settled upon a firm legislative basis.

THE HARVEIAN ORATION.

It must be a difficult question for the Fellow of the Royal College of Physicians, London, who is honoured with the appointment to deliver the Harveian Oration, to decide how he ought to treat the subject. There is a natural tendency to exaggerate the claims of a great man of the past upon the gratitude of the present, when those claims are put forward in an address to a meeting called for the

purpose of hearing a panegyric in their laudation. At the College of Surgeons the memory of John Hunter as a surgeon and anatomist is once a year thus treated; while at the College of Physicians, the memory of William Harvey as the discoverer of the circulation of the blood, and as a physiologist, is kept alive by an oration. So much has been said about the discovery itself and the claims of Harvey to honour for discovering what was new and original that nothing can be added to what has been done in this direction. This year Dr. Poore has chosen to analyse the motives which prompted Harvey in the work he loved to do, and to hold him up as an example which now and at all times must be followed by those who desire to add to human knowledge. He dwelt upon the glorious pleasure derived from the study of Nature as being beyond that afforded by any other occupation in life, and how the value of research and experiment exercised in freedom from fancy and imagination, is of the greatest influence in raising the mind above the lowering tendencies of much that attracts and occupies the world in general. The Oration was delivered with grace and dignity, and was appreciated highly by those who listened to it. There could have been very few who regretted the change made in 1865 from Latin to English, and the support it received from Sir Thomas Watson, when he was president, may be recognised as evidence, that high scholarship may be combined with good common sense. Dr. Poore's text was, in the words of Harvey's gift, "to search and study out the secrets of Nature by way of experiment." But this was not so much the purpose for which Harvey intended the oration, as that it should be in "commemoration of all the benefactors of the said college, with an exhortation to others to 'imitate these benefactors.'" We fear that the reason why this purpose of the Annual Oration has received but little attention is because there has been little reason for its doing so. Why so few should leave anything when they could well afford to give generously, and when they must be aware how little the College possesses, it is difficult to understand. In the City we see a very different spirit prevailing, and it would be well for the Harveian orators in the future to exhort others to "imitate" far more than they do. Harvey was not the man to want his name extolled to the skies, "for to do so would not be to search and study out the secrets of nature." The spirit in which he worked requires encouragement as much to-day as in Harvey's time, and we hope this will be kept in view as Dr. Poore has done, by future Harveian orators.

Notes on Current Topics.

Instruction in Dispensing.

ONE of the most serious arguments advanced by pharmacists in their attack upon the practice of allowing medical men to dispense their own medicines is the utter inadequacy of the instruction provided by our medical schools in that department.

Some half-dozen attendances in the dispensary is usually all that is demanded of the student, and as the dispenser in chief has his hands full of other work it can easily be imagined that the future practitioner escapes with a modicum of practical teaching. Even a diligent student under the most favourable circumstances cannot be expected to obtain much insight into the practical details of pharmacy, nor do we see how it can be otherwise. To allow every tyro to educate his hand by assisting in the dispensing department of public institutions would be to court disaster. There is really only one way to learn dispensing other than by putting in time with a retail chemist, and that is in the surgery of the busy practitioner, but this unexceptionable way opportunity was virtually wiped out of existence by the General Medical Council when the abolition of the old-fashioned apprenticeship was decreed. It is still open to the senior student, it is true, in his last year, to avail himself of this opportunity, but the fact remains that but a infinitesimal proportion of the general body of students do avail themselves thereof, and as a rule the newly qualified man has to learn it as best he may on commencing practice. It seems to be forgotten that dispensing is an indispensable department of the practice of medicine, even though the practitioner may not take up a class of practice in which dispensing is admissible. A practical knowledge of pharmacy is a necessary step to writing good workable prescriptions, and the decay in the standard of prescription writing which characterises the present generation of medical men is directly attributable to their want of instruction in this department. The result is seen in the ever increasing disposition to have recourse to ready-made preparations of which the manufacturing chemist is yearly becoming more profuse. In France, where dispensing has always been more or less tabooed, the empire of the speciality is absolute, and prescribing proper is a lost art. We are not concerned to deny that dispensing "pays," but that fact, if fact it be, is rather another argument in support of the contention that better provision should be made for teaching it. What with doctors who have never learned to dispense, and unqualified dispensers who have had no practical training in their duties, it is something to be thankful for that accidents are so rare, and disaster so infrequent. Room ought to be made in the curriculum for the subject, and we would appeal to the members of the General Medical Council to see that the subject receive the attention it deserves.

A Protest Against What?

DR. W. W. KEEN, of Philadelphia, is one of the rare American surgeons who do not believe in eliminating every appendix which makes its presence felt. At a recent meeting of the American Medical Association he declaimed as follows:—"I protest against the argument that every case of appendicitis ought to be operated on, and that the appendix is never to be left. Out of 300 post-mortems on as many bodies it was found that 100 of the individuals had had appendicitis at some time in

their lives and had all recovered from the disease. I dispute the assertion that through surgical operations all but 2 per cent. can be saved. I challenge any operator in the room to take 100 well persons, and operate upon them without killing more than 2 per cent. We all fail, gentlemen. I do not know why, but we all fail. I do not believe in operating on all sorts of appendicitis. I'd rather have a live man with an appendix than a dead one without. I do not believe with the witty Frenchman that no case is complete without an autopsy. If the patient is no worse after forty-eight hours of observation, let him alone, let him get well." We cannot but wonder what windmill this medical Don Quixote is tilting against. Whoever, in the land of Nicholas Senn, advocates operation unless (1) the condition is of itself serious, or (2) has recurred on several occasions? We have never heard anyone advocate removal of this intestinal tag for a first offence, unless of a very heinous description, and if it prove incorrigible—by medical treatment—there is nothing for it but to pluck it out.

The Rating of Hospitals.

WE have received a number of communications concerning the proposed exemption of hospitals from rating, a subject which we dealt with last week. It is pointed out that to exempt a hospital from the payment of rates is tantamount to making a donation to the funds of the institution equivalent to the amount which would otherwise be paid. This, then, is the first step in the direction of the municipalisation of medical charities but with this disadvantage—that whereas if the municipality voted a certain sum *per annum* to the funds the gift would convey the right to be represented on the management which mere exemption from rates does not. Then, too, it is urged that there are other charities besides hospitals, which, once the thin edge of the wedge introduced, might reasonably claim to have similar treatment meted out to them, and this would land us in a dilemma, because many of these charities are more or less denominational in character, and if any claim were admitted, the others must necessarily follow. A more practical suggestion is that a better means of helping these institutions would be to agitate for the remission of the ten per cent. legacy duty which is now levied by Government on all bequests for charitable purposes, and in this we heartily concur.

Public Health and the Profession.

DOUBTLESS the editor of the *Public Health Engineer* is wise in looking to the medical profession for aid in carrying out those reforms in all matters affecting the public health, and which require care and study. It cannot be questioned that the profession generally, particularly the younger members of it, are devoting attention to those necessary evils which arise in great towns, and which are the cause of much illness. No class of men are so well prepared to study matters of public health as those who have entered the pro-

fession and if we look back to the chief influence that has been exerted during the latter half of this century on the advancement of sanitary science, we see how much is due to our profession. The *Public Health Engineer* will be found to contain a great deal that must be of interest to all practitioners particularly those who are required to consider in their practice the maladies which arise from overcrowding and other injurious conditions common in crowded communities. Through the profession the public is more likely to be educated in such matters than in any other way, and we think that it will add to the esteem in which the public holds it if it assists in this work of education.

The New Entries at the Medical Schools.

THE returns of the new entries at the medical schools in England has just been issued, and, judging generally from the numbers, a falling off is noticeable in this respect. In the London schools St. Bartholomew's heads the list, as usual, with 115 new students for the whole curriculum; next follows the London, with 83; Guy's, with 79; St. Thomas's, with 59; St. Mary's, with 50; University College, with 35; St. George's, with 27; Charing Cross, with 26; Middlesex, with 24; King's College, with 21; Westminster, with 17; and the London School of Medicine for Women, with 17. In the provinces; Cambridge University claims 141 new entries Owens College, Manchester, 76; University College, Liverpool, 58; University of Durham, 32. This Northern University seems to have fallen upon evil times. A few years ago it had an entry of 1,198 students for the whole course. Why, then, this retrograde record? Of the Metropolitan schools the most successful list is certainly that of the London Hospital. Apparently, the profession, as well as the public, appreciate the forward policy which has been displayed in the management of the institution. The small entries at several of the other schools is suggestive of the reflection that the authorities concerned must have a very difficult matter in making both ends meet.

What is Fibrinous Rhinitis?

A DIFFERENCE of opinion exists among throat specialists as to the real etiology of what is called fibrinous rhinitis. In a paper fully discussing the subject, Wishart, of Toronto, in the current number of the *Canadian Journal of Medicine and Surgery*, quotes Lennox Browne and Walsham in this country, and Bosworth in America, to the effect that the disease is a benign one, distinct from diphtheria, and that it is non-contagious. On the other hand, Ravenel, of Philadelphia, holds that "patients suffering from fibrinous rhinitis are always a possible source of contagion, and that they should be isolated like those affected with the more common types of diphtheria." Thus two practically divergent views are held respecting the etiology of the disease. The author, in describing his own cases, states that they were certainly diphtheritic, but of an unusually mild character. He

further adds that in a collected series of ninety-eight cases the Klebs-Loeffler bacillus was present in sixty-nine. This result is again at variance with those who affirm that this bacillus is never found in cases of the kind. From his observations, then, he submits that the accumulated evidence seems to prove (1) that fibrinous rhinitis and diphtheria are not distinct diseases; (2) that all cases of the disease need the same precautions as to isolation that diphtheria requires. It is curious that such diversity of opinion should prevail in regard to this disease.

The Guild of St. Luke.

THE Annual Festival Service of the Guild of St. Luke was held at St. Paul's Cathedral on the 19th inst., and was largely attended. The Lord Mayor and Sheriffs were present in State, accompanied by the chief officers of the Corporation and members of that body. In the procession which passed up the nave the members of the Guild and their friends were robed in their various coloured gowns, and a very striking scene was thus produced. A choir of three hundred voices, furnished by the London Gregorian Choral Association, rendered most efficiently the musical part of the service. The sermon was preached by the Bishop of Stepney, the Canon in residence, his text being: "Jesus went about all the cities and villages, teaching in their synagogues, and preaching the Gospel of the kingdom, and healing every sickness and every disease among the people." In drawing a comparison between the clerical and the medical professions, the Bishop proceeded to discuss how the two professions might draw closer together, expressing the opinion that the clergy should bear more in mind the value the medical profession placed on accurate observation. If the training of doctors, he said, made them on that account more slow to accept the truths of religion, then the clergy should sympathise and appreciate that. Still, medical men should bear in mind that there was a science of medicine as well as a science of theology. The reasons, for example, for the clergy believing in baptism were based on as sound deductions as the reasons the doctor had for believing in vaccination. All the truths of religion required as much balanced thought and deep studies as anything taught in the hospitals. The Bishop incidentally mentioned that the late Bishop of Bloemfontein was the only clergyman who was a Fellow of Royal College of Physicians (London). The discourse was listened to with keen attention, and the appositeness of many of the points to which expression was given must have been forcibly impressed upon the audience which thronged the cathedral.

Leicester Triumphant.

THE citizens of Leicester are triumphant, inasmuch as the official returns for the week ending October 14th showed a remarkable reduction in the local mortality. The number of deaths in the town was only 49, or a decrease of 11 as compared with the corresponding week of 1898. Thus "an almost ideal death-rate," as the *Leicester Daily Post* described it, of 12 per 1,000

was attained. Despite, however, this apparently strong proof of the salubrity of the town, diphtheria seems to be very prevalent, a condition of things which should surely be capable of improvement. The people of Leicester are, nevertheless, to be congratulated upon the lowness of the death-rate, and hence it is that regret must be felt that they cannot forego the absurdity of ignoring the vaccination laws. Of this the townspeople may rest fully assured, that by courting an epidemic of small-pox by refusing the protection of vaccination, their "ideal death-rate" is likely before long to be speedily disposed of. It is an especially dangerous and inexpedient policy to trifle with a zymotic disease as virulent as variola.

Revocation of the Muzzling Order for London.

RECENT reports to the Board of Agriculture show that for some time past the Metropolis has been quite free from rabies, so that the Home Secretary is at last enabled to defer to the popular feeling in favour of rescinding the Muzzling Order in so far as that area is concerned, and its withdrawal is to take effect within the next few days. While we cannot but feel satisfaction at the excellent result achieved by this measure in the teeth of active and persistent opposition, the wisdom of allowing dogs to run loose in our large cities is one that may fairly be called in question. The crowded centres of population are ill-suited for dog life, and as the transformation of London into a city of flats proceeds this will become more and more obvious. When next the County Council requires to look round for a fresh source of income, they cannot do better than apply to Parliament for power to levy a supplementary tax on town dogs, a municipal tax as in addition to the Government tax. This would discourage people from keeping dogs under conditions which are unfavourable to the well-being of the animals themselves and dangerous to human beings. The only Muzzling Order that will remain in force is that applying to South Wales, and even this, it is hoped, may be dispensed with before the end of the year. After such a decisive experience we suppose that none will question the efficacy of this ready means of stamping out rabies. We presume, however, that the precautions with respect to imported dogs will be maintained, otherwise the respite from hydrophobia may prove but ephemeral.

Atmospheric Climatology and Health.

WHAT we understand by climate is in the main an average of the vicissitudes which characterise the atmosphere of a given place. Some climates are described as bracing, while others are said to be enervating, but these terms are only relative because climate is but one factor in the production of physiological effects, the other factor being individual temperament. No very clear idea obtains of the physical conditions which underlie the influence of climate, but certain considerations throw light on the conventional meaning attached to these terms. A dry wind is bracing because in the healthy organism it provokes

free perspiration and evaporation and the cold thus caused stimulates the individual to muscular exertion in order to make up for the loss of heat. The physiological activity thus engendered is reflected in an increase of appetite and a heightening of functional activity. Moreover, as the air contains only a comparatively small percentage of moisture the proportion of oxygen is *pro tanto* larger. The opposite conditions obtain in a moist atmosphere, especially if a low temperature be superadded. The functions of the skin are reduced to a minimum, and the presence of moisture at, or about saturation point in the air, displaces so much oxygen, just in the same way as in administering chloroform the life-maintaining air is displaced by the vapour which, if present in unduly large proportions, leads to asphyxia. A very hot air, it is true, if dry, stimulates the excretory functions of the skin, but it acts unfavourably on the muscular system because the heat already being excessive the tendency is naturally to avoid movement which would add to the body heat. Moreover a hot air means more or less rarefied air, and as the volume of air increases with every additional degree of temperature it follows that a given bulk of hot air contains proportionally less oxygen than the same quantity of cold air. Respiration is, therefore, increased in rapidity to make up for the deficiency. With hot air which is also moist the conditions are distinctly unfavourable to health and comfort. Nature's plan of resisting the tendency of the body temperature to rise above normal, by provoking perspiration and free evaporation, is hindered by the inability of the air to take up more moisture, and a condition of discomfort supervenes. In normal health the human machine works at such low pressure that there is ample margin, but if any of the vital functions happen to be disorganised unfavourable climatic conditions may promptly turn the scale in the direction of disease.

Royal Academy of Medicine in Ireland.

THE annual general meeting of the Royal Academy will be held in the Dublin College of Physicians, on next Friday, October 27th, when the election of officers will take place. The following Notices of Motion will come up for discussion. 1. "Rule 67.—The Academy, however, shall not hold itself responsible for the payment of the printing of such papers, unless they are deemed by the General Council suitable for publication in the 'Transactions.'" 2. "That the following be elected Honorary Fellows of the Academy:—Sir J. Burdon-Saunders, Oxford, Prof. Howard Kelly, Baltimore, Prof. Koch, Berlin, Prof. Kocher, Bern, Prof. Th. Leber, Heidelberg, Sir W. MacCormac, London, Prof. Martin, Berlin, Prof. Nothnagel, Vienna, Prof. Osler, Baltimore, and Sir W. Turner, Edinburgh." 3. "That the Council be authorised to nominate Corresponding Members of the Academy from time to time." 4. Dr. F. W. Kidd—"That any Fellow dropping his subscription for a year or more may be readmitted to his Fellowship on payment of subscription of current year, without the payment of an

entrance fee, should the general council approve." The report of the Council presents the Academy in a fairly flourishing condition. The number of Fellows, for the past session was 240, of members 32, and of associates 20, and in each class there has been a slight increase. The finances are, however, not so satisfactory, inasmuch as the year commenced with a credit balance of £21 in bank, and ended it with an overdraft of £33. In other words, a loss of over £50 was sustained, which the Council attributes to the purchase of £100 worth of microscopes. This was, however, an exceptional and a necessary item of outlay, and will be readily approved, but we cannot recognise equivalent value to the Academy for the item of £172 for printing the transactions which, unless they be indispensable as a record of the work done, for preservation in libraries, are, we say, of no use whatever to the Academy. A *rechauffe* of papers read at the sections, issued as it necessarily is, nearly a year after the reading, and usually many months after interest has waned in the subject of which they treat, is not readable matter then or thereafter, and, as a matter of fact, we will undertake to assert that not one in a hundred of the Fellows makes any pretence of perusing them. We observe, also, that the Royal Colleges of Physicians and Surgeons each accept fifteen guineas a year for the gas, coal, and attendance required for the sectional meetings, and we consider it entirely beneath their dignity to accept such a tip from an institution maintained for the advancement of medicine and surgery in Ireland. If this sum of thirty guineas were added to the £172 which is wasted on printing of the Transactions the Academy would be in a position to do something handsome to advance its legitimate objects.

The Chemical Diagnosis of Gastric Disease.

It is to be feared that the striking progress which has been effected during the last ten or fifteen years in the diagnosis of diseases of the stomach by chemical examination of the gastric contents is not reflected in the methods employed to arrive at a diagnosis in general practice. One continues to prescribe acids or alkalies more or less at hazard, in ignorance of the precious information that can be gleaned by a few examinations of the gastric contents. This aspect of gastric diagnosis was very lucidly explained in a lecture recently delivered by Dr. Vaughan Harley at University College, and subsequently published in the *Practitioner*. The lecturer insists on the importance, from a therapeutic point of view, of ascertaining by direct observation the nature of the gastric contents after a test meal, for by this means it is possible to ascertain the precise nature of the disturbance, and even to provide data for a scientific diagnosis of the physical conditions underlying that disturbance. This method, which is carefully described, furnishes the only trustworthy means of distinguishing between dyspepsia associated with excessive secretion of free hydrochloric acid and the forms in which this constituent is wanting. Without this information treatment must be empirical and may even be detrimental. The existence of a gastric ulcer and the recent

occurrence of hæmatemesis are the only contraindications to this method of investigation, and the discomfort which the procedure entails to the patient is amply compensated by greater efficacy of treatment. The amount of mucus and the proportion of volatile acids in the gastric contents are details of considerable importance, but it is also possible to estimate the degree of dilatation in cases of gastroptosis, and by microscopical examination to define the nature of the fermentative changes going on. In short, we can trace the affection to its immediate cause and decide to what particular error of diet or function it is attributable.

Scalpel *versus* Hooked Nails.

A GOOD deal is heard of the experiments upon lower animals necessary to carry out research upon the origin and the cure of the various diseases that affect mankind. On the other hand little is said about the barbarities every day perpetrated in the sacred name of sport. In an account of a run by the Queen's Buckhounds on October 13th it is stated that the deer failed to clear a five-foot fence with hooked nails running along the top of it, at Farnwood, and was suspended for a minute or two by one of the hind legs. After some of the nails had been pulled out by the struggles of the unfortunate creature it got away. This is the kind of experience that the Duke of Portland deliberately claimed in St. James's Hall, at a public meeting of the anti-vivisectionists, was good for the deer, on the ground that they were preserved from extermination by the sportsman. We venture to say that scientific men who carry out carefully considered experiments upon the lower animals would recoil in horror from the thought of driving a deer to suspend itself by the hind leg from a barbed five-foot fence. The aims of the scientist, however, are for the good of humanity in general, whereas those of the sportsman are for the amusement of the individual. The sportsmen, if attacked by deadly disease, say the plague, gladly avails himself of discoveries that could only have been made through the agency of vivisection, that is to say by inoculation experiments. So would any anti-vivisectionist of them all, for that matter; but why do these sentimentalists strain at the scientific laboratory while they swallow the Queen's Buckhounds?

The "Barker" Anatomical Prize.

THE Council of the Royal College of Surgeons of Ireland, with whom rests the grant of this Prize, has been unable to confer it this year upon any one. The Prize is for the best dissection of a special region, put up as a Museum preparation, and, apart from the distinction which the winning of it confers, it is worth £21 in cash. We regret to learn that the reason why it has not been awarded this year is that but one competitor entered the lists, and his dissections were not considered to show sufficient merit. It certainly seems strange that a valuable distinction like this, which is within the grasp of every assiduous anatomical student, is not sought for by more than one or two.

Irish Poor-law Doctors' Holidays.

AN important legal opinion has been presented to the Guardians of the Boyle Union by the MacDermott, Q.C. He advises (a) that the Local Government Board has power not only to approve but to direct the payment of a reasonable fee for locum tenens' work; (b) that no part of this payment can be deducted from the salary of the absent medical officer without special sanction; (c) that practitioners can effectually sue the Guardians for services rendered as consultant; (d) that there are no regulations "applicable to workhouse medical officers of later date than the General Orders of October 18th, 1882, which enable guardians to give reasonable compensation to a substitute"; (e) that, under the new rules, the dispensary medical officer is not entitled to a full month's holiday if the guardians refuse to give it to him.

The Value of Glycerinised Calf Lymph.

THE use of glycerinised calf lymph in vaccination has met with high approval in America. Dr. Albert C. Barnes, of Philadelphia, in an elaborate inquiry into the subject has shown that the successful inoculations amount to from 90 to 100 per cent., in the cases in which it is employed in primary vaccination. Moreover, the lymph has many other obvious advantages which experience has plainly demonstrated.

Insanitary Areas.

THE London County Council is making an effort to do away with some of the insanitary areas with which London is riddled. The Working Classes Committee have recommended the Council to deal, under Part I. of the Housing of the Working Classes Act, 1890, with several areas that have been declared insanitary by their local medical officers of health. In each case it is proposed to build on the sites accommodation for more persons than it is proposed to displace. The sums that will be actually disbursed in carrying out these schemes will be enormous, notwithstanding a business-like handling by the Council of increased values and surplus lands. The first scheme deals with property in Shoreditch, where it is proposed to clear an area of two three-quarter acres in extent. Considering the value of land in these densely populated districts the contemplated net expenditure of £144,850 does not seem too extravagant. The next scheme is for the benefit of the unsavoury neighbourhood of Leather Lane, Holborn, where 1,402 persons are to be dislodged, and where rehousing accommodation for 1,400 is to be provided at an estimated net cost of £169,800. The third scheme embraces two large areas, nearly seven acres in extent, in the poor and densely crowded Parish of St. George's, Southwark. In this instance, the total net cost of clearing and rebuilding is estimated at £152,590. Lastly, there is a small scheme to carry out similar operations in Poplar at a cost of £16,500. With the general principle involved in these clearances all sanitarians will probably agree. It is to be regretted, however, that no provision has been made for converting

part of the areas into open spaces, and that some way of rehousing the displaced inmates during rebuilding has not been devised. Under present conditions they will be driven away into distant suburbs.

"Physician" and "Apothecary."

IT will be recollected that much excitement was created a couple of years ago within the ranks of the Licentiates of the London Apothecaries' Hall, by the prosecution, under authority of the General Medical Council, of Mr. Hunter, a licentiate of the Hall, for calling himself a "physician" and "surgeon." It was admitted that the terms of the Medical Acts entitled him to practise medicine, surgery, and midwifery, but the rival colleges maintained that while he could do this as an apothecary, he could not call himself by any other name, and the High Court sustained this contention. Apparently the Hall is determined to carry the dispute to the House of Lords, for it has obtained the opinion of Sir Edward Clarke, which is diametrically opposed to this decision. He urges that it is a *reductio ad absurdum* to license a man by Act of Parliament to practise medicine and surgery, but to forbid him to call himself "physician" or "surgeon."

New Use for the Irish Dispensary.

A FORTNIGHT since we referred to the fact that the Guardians of the North Dublin Union had made an order that the outdoor relief to paupers should, henceforth, be distributed at the medical dispensary house of each district, and we urged that such an arrangement was highly objectionable from the sanitary and every other point of view. We note with satisfaction that this objectionable order has been withdrawn, and in future the dispensary house will be devoted to its legitimate use.

PERSONAL.

DR. JAMES DUNSMURE has been elected President of the Royal College of Surgeons, Edinburgh.

MR. A. O. DAVIES, M.R.C.S., of Machynlleth, has been appointed a Magistrate for the County of Montgomery.

MR. T. I. BIRKIN has offered to place at the disposal of the managers of the Children's Hospital, Nottingham, a mansion known as Forest House, with an adequate amount of land, for the purpose of a larger hospital, the present buildings being quite inadequate.

MR. ARTHUR HAMILTON WHITE, Professor of Pathology and Bacteriology in the Royal College of Surgeons in Ireland, and sometime assistant in the Pathological Laboratory of University College, has been appointed Pathologist to the Meath Hospital, Dublin.

AFTER the delivery of the Harveian Oration at the Royal College of Physicians of London on Thursday last, the Baily medal was awarded to Professor Sherrington, of University College, Liverpool; and the Bisset-

Hawkins medal to Dr. Burn Russell, for his services to sanitary science during the past decade.

AT the close of the mayoralty of Dr. Finny, of Kingston-on-Thames, next month, the Speaker of the House of Commons will unveil a new stained glass window in the Town Hall. After the ceremony Dr. Finny will entertain the Corporation, magistrates, and representatives of public bodies at a *déjeuné*.

DR. WALLACE, of Steventon, has recently been the recipient of a presentation by the inhabitants of Steventon in the shape of a specially constructed brougham and an illuminated address as a recognition of his valued services as medical practitioner in the town for the past thirty-eight years.

THE King of Greece having conferred the Royal Order of the Saviour, in recognition of services to the Greek wounded during the late war, on Mr. F. C. Abbott, F.R.C.S., Mr. Samuel Osborn, F.R.C.S., Mr. Hy. A. Moffatt, F.R.C.S., and Mr. R. Fox-Symons, M.R.C.S., Her Majesty the Queen has granted unto the recipients Royal licence to accept and wear the insignia of this order.

THE Home Secretary has notified the Mayor of Newcastle-on-Tyne that the Queen has been exceedingly gratified to hear of the Jubilee Commemoration for the erection of an infirmary, towards which the public have subscribed the magnificent sum of two hundred thousand pounds. It is understood that although her Majesty will be unable to lay the foundation-stone in person, she will be pleased to depute a member of the Royal family for the ceremony.

A DEPUTATION of the chief magistrate and Town Council of Berlin waited on Professor Virchow, on Friday last, and congratulated him on his fortieth anniversary as member of the Berlin Town Council. Virchow, our correspondent says, was greatly overcome by the unexpected ovation, and after thanking the deputation for the honour done him, said he regarded communal activity as the first duty of the citizen next to the care of his family, and he was proud to have been able to fulfil this duty to the satisfaction of his fellow citizens for so many years.

Scotland.

[FROM OUR SPECIAL CORRESPONDENT.]

UNIVERSITY OF GLASGOW.—At a meeting of the University Court on the 17th inst., it was announced that the trustees of the late James B. Thomson had made a grant to the University of £10,000 to be applied to the reconstruction of the anatomical department of the University. With this handsome legacy in hand we hope to see the present corrugated iron building removed before the 1901 Exhibition, which will, no doubt, bring many strangers to the city. The several medical schools and the University are very busy just now. In the University the matriculation, which began on the 18th inst., is quite exceptional this session, the numbers as yet far exceeding those of the past few years. The number of students who matriculated on that day numbered 350, and it is anticipated that this number would be exceeded on the following day. The new professors have made

their *debut* amidst great acclamations of delight, the students giving each one a right royal reception. Professor Gray comes back, so to speak, to his former hunting grounds, as he is a Glasgow student, and at one time assistant to Lord Kelvin. The successors to Professor Murray and Professor Lodge are entirely new to the University, but from their initial start it is expected that the chairs will be ably filled.

ANDERSON'S COLLEGE.—The winter session was opened on the 20th, and from all appearances there is every indication of a good session, the enrolment of students with regard to numbers being considered most encouraging and satisfactory, as an unusually large number of students have already enrolled. Professor A. M. Buchanan, of Anderson's College, Professor of Anatomy, we are pleased to say is back again to duty, his health being quite restored after his serious and prolonged illness. It is a great gratification both to his colleagues, students, and to all who have the pleasure of his acquaintance that he is able to resume his professional teaching.

ST. MARY'S COLLEGE.—Winter Session was opened on the 20th inst. with an introductory address by Professor Barlow, who took for his peroration, "How to Become a Medical Practitioner." He said, of the five intellectual professions relating to the necessities of life, the medical profession must be regarded as the most beneficial. It was always full of scientific interest. It was, however, he thought at present overstocked, but there was still plenty of room at the "top." He pointed out the advantages of the school in being attached to the Royal Infirmary, and exhorted the students to uphold the reputation of the College. Here, as in the other medical schools, a large number of students have been enrolled.

UNFOUNDED CHARGE AGAINST NURSES.—For some time past complaints have been openly made by some dissatisfied parents that during the time their children were in the fever wards of the Paisley Infirmary they were cruelly treated by some of the nurses. The complaints having been submitted to the directors of the Infirmary, they have since made careful investigation regarding the charges, and have now issued an official communication denying that there are any grounds for charges made against any of the nurses.—The fever outbreak in the town shows a very serious increase in the number of cases, scarlet fever and enteric fever being the principal cause of the increase, which brings up the total to 152. 31 new cases having been admitted during the week.

MEDICAL SOCIETY OF LONDON.

The meeting on Monday evening last was devoted to a discussion on "The Infectivity of Malignant Growths," initiated by Mr. Bellingham Smith and Dr. Washbourn, in a paper which embodied the following conclusions—(1) Malignant growths may be regarded as local in origin and as possessing the power of infecting adjacent and distant parts of the individual; (2) Inoculation may take place from one part to another of the same individual apart from transmission by the natural channels; (3) There is good evidence to show that one individual may be infected with growth from another; (4) There is experimental evidence to show that growth may be transferred from animal to animal of the same species by inoculation; (5) There are found in many malignant growths bodies which have a resemblance to micro-organisms and which have been regarded as belonging either to the protozoas or the blastomycetes; (6) a new growth having the structure and also the behaviour of carcinoma has been described as occurring, and at any rate in two instances, from inoculation with a form of blastomycetes; (7) These experiments are highly suggestive that the bodies found in cancer are the cause of the disease, though evidence is wanting that the two are directly associated.

Mr. J. Jackson Clarke concurred in the views of the authors, and Dr. Symes Thompson mentioned an instance in which two men who had married two sisters, but who were not otherwise related, both developed cancer of the

tongue; also a case in which an epithelial cancer of the tongue was followed by sarcomatous growths in the neck.

Dr. Heywood Smith related a case in which he felt convinced an ovariectomised woman had been infected from a patient who had been previously operated on for malignant disease of the ovaries.

Dr. Lacke combated the parasitic theory, urging that the actual cells were conveyed, and Dr. Auld thought the type of growth was dependent upon the conditions present at the site of transplantation.

Dr. MacFadyan insisted on the necessity in this discussion of clearly distinguishing between connective tissue and epithelial growths, and suggested that growths described as sarcoma might merely be the reaction of the tissues to living irritants. He urged that there was no dissimilarity between the structure of sarcomata and many bacterial growths, which would negative the possibility of some of them at any rate being due to bacterial irritation. He recalled the fact that actinomycotic tumours were formerly described as sarcomata. In respect of transplantation, he asked for examples of this sort occurring with lesions known to be parasitic.

Dr. Washbourn then replied, remarking that veterinary pathology had not yet reached a stage which would enable it to throw much light on these questions, and he anticipated that future observation would show growths of this class to be much more common in the lower animals than was at present thought.

Correspondence.

We do not hold ourselves responsible for the opinions of our correspondents.

"ANÆSTHETICS."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Under the heading "A Correction," a letter appears in your paper of to-day from Mr. E. Willett taking exception to my figures in the review of St. Bartholomew's Reports.

Had Mr. E. Willett's letter been marked "A Vindication" the heading would have been more accurate. He accurately quotes my figures, to wit:—"During the year 1897 anæsthetics were administered 4,893 times, chloroform 1,959 times, ether 201 times." But he goes on to say that gas and ether were administered 1,261 times. He, however, overlooks the fact that I distinctly stated chloroformisation and etherisation.

The fact that gas preceded ether in so many cases goes, I think, to show that etherisation pure and simple was not found suitable in those 1,200 odd cases, and that the drug of itself was seldom used even by its warmest advocates.

By the method referred to by Mr. E. Willett, many of its more dangerous and unpleasant effects are got rid of; withal, we find that even under such favourable conditions chloroformisation was adopted in more cases than etherisation and gas and ether anæsthesia by gentlemen whose partiality for ether, as against chloroform is notorious.

I thank Mr. Willett for so pointedly vindicating my statement as to the value of chloroform as a safe, efficient, and generally useful anæsthetic.

I am, Sir, yours truly,

THE REVIEWER.

Infectious Disease in Liverpool.

AN alarming increase in the number of cases of infectious disease is reported from Liverpool. Scarlet fever has increased from 1,600 to 1,800; measles from 1,900 to 3,600; typhoid fever 718 as against 541; while in respect of diphtheria the number has risen from 327 to 575. This disquieting state of things is engaging the attention of the Sanitary Authorities, who are greatly hampered by the inadequate accommodation at present available for the reception of the sufferers.

Literature.

DISEASES OF THE STOMACH. (a)

It was to be expected that sooner or later we should get a volume on gastric disorders from the American School. The diseases of the stomach have latterly lent themselves largely to methods of chemico-physical examination, and of late years the American school have shown a remarkable aptitude for that direction in medical work. The authors of the present work produce a volume which shows an extensive acquaintance with the work on the same lines done in Europe, while at the same time one it bears the impress of an extensive clinical experience.

The work is divided into six sections of which the first is only introductory. The second deals with general diagnosis and describes very fully the most modern methods of investigation of the gastric form and functions, without neglecting the older ones, which will never lose their importance, however the newer methods may be modified or superseded. The third section, of a hundred pages, deals with the general principles of treatment and contains much valuable matter on dieting. The relative value of natural and so-called artificial foods, and their appropriateness in various conditions, are fully discussed. In Sections IV. and V. the diseases of the stomach are discussed in detail under the heads of dynamic and anatomical respectively. The dynamic affections are considered in three classes—the sensory, the secretory, and the motor; while the anatomical division deals fully with gastritis, ulcer, cancer, and displacements. We confess to being incompletely satisfied with this classification, and hardly persuaded of the diagnostic individuality of some of the diseases included in the dynamic group. Thus, *adenohypersthenia gastrica* (what a rattlesnake of a name!) is capable of analysis into *hyperchlorhydria*, *digestive hyperchylia gastrica*, and *paroxysmal hyperchylia gastrica*. No doubt, to the specialist in gastric diagnosis such names are valuable symbols for his conceptions or knowledge of morbid states, but we have no proof that they really represent morbid entities; and we are not without fear that to the easily satisfied disciple they may bring such comforting self-conviction of knowledge as is recorded of "that blessed word of grace, Mesopotamia." But the fact remains that all or almost all the phases of gastric disease are described here with a detail which has hardly any other fault than that of occasional overlapping.

The last section deals with the inter-relations of stomach disorders with those of other regions, and we could have wished that it had been fuller. The rest of the book is so complete and satisfactory that we are disappointed at not having a more extensive discussion of the relation of the morbid stomach to such conditions as chronic nephritis, gout, gall-stones, neurasthenia, and others. Perhaps, however, the authors desired to avoid the not uncommonly merited opprobrium of the specialist, that he would reduce the whole world of pathology to his own petty horizon. We can cordially recommend the volume before us as an up-to-date exposition of the diagnosis and treatment of gastric disorders.

TALBOT ON DEGENERACY. (b)

ONE rises from the perusal of this book—one of the Contemporary Science Series—with the feeling that the author has written an interesting and instructive volume, and while one may feel that he has viewed the subject too widely *qua* degeneracy, and gone over entirely to the school of wholesale degeneracy; he treats of the matter with a wide knowledge of the literature of the subject, and quotes freely, and often in a most apposite and intelligible manner the views of the many who have written on different branches of the subject. To the

many authorities quoted ample acknowledgment is made, and we would merely criticise to the extent that in the historical *résumé* at the beginning of the work there is a want of chronological sequence here and there that is rather disheartening, and a closeness of quotation that at times makes the page look more like a biographical index. On the subject of causation the author is perhaps not so exhaustive as he might be, and on the heredity of epilepsy he pins his faith too much to experiments on animals. His frank confession that in America, as late as the date of the Guiteau trial, a school of eminent men existed who denied certain well ascertained facts in human degeneracy is astonishing. Alongside this we are glad to recognise as advanced men and sound thinkers many who have since made their name in American psychiatry. On the subject of heredity of acquired defects we are quite in accord with the author, and note with pleasure his repudiation of the views of Weismann. In this relation his quotations of exceptional experience on the hereditary results of circumcision are valuable. A glance at the book will satisfy the reader that the author has enhanced a wide range of topics related to the subject, but they are not all treated at length, or the volume would extend to great dimensions. None the less are we disappointed that more has not been said regarding them. Thus we should like to read more of such practical subjects as the influence of opium eating, of unequal and immature marriages, alcoholic excess, &c., on the progeny. The work is specially intended for educators and parents. Its chief aim is to state general principles and to serve a practical purpose. In a large measure it has achieved its purpose.

MAX VERWORN'S PHYSIOLOGY. (a)

PROFESSOR VERWORN'S book is already well-known to English biologists in its original German dress. Professor Lee's clear and idiomatic translation cannot fail to introduce it to a much wider circle of readers, and the time of its appearance is opportune.

For although both the student of medicine and the physiological specialist are already well provided with text-books of physiology in the ordinary sense, it is not possible that in any of these, the general problems of life and the general phenomena of living things, should be so exhaustively dealt with as in a treatise exclusively devoted to their consideration. Until recently, indeed, the materials for a book on general physiology were so scanty and so scattered that but little fruit might have been expected from an attempt to bring them together and to arrange them in logical order. But in the last twenty years it has become more evident that all the deepest questions of the special physiology of particular organs or organisms are in the last analysis questions of the physiology of the cells of which these organs or organisms are built up. Physiology has, therefore, in an ever-increasing degree, and with continually augmenting success "extended its inquiries to the cell." The result is the imposing and interesting body of knowledge for the first time systematically unfolded and adequately discussed in the volume before us.

Starting with a suggestive, though somewhat discursive chapter on the aims, the history and the methods of physiological research, the author next considers the general, chemical, physical and morphological properties of the living substance. His defence of the view that the living substance is of liquid rather than of solid consistence, and this exposition of the present state of opinion as to the structure of the nucleus seem to us particularly strong features of this portion of the work. The elementary vital phenomena are then passed in review. Under this head are included the phenomena of metabolism, the changes of form that occur in development (with discussions on heredity, cell-division, and

(b) "Degeneracy: Its Causes, Signs, and Results." By Eugene S. Talbot, M.D. London: Walter Scott, Limited.

(a) "General Physiology, An Outline of the Science of Life." By Max Verworn, M.D., Ph.D., A.O., Professor of Physiology in the Medical Faculty of the University of Jena. Translated from the Second German Edition, and edited by Frederic S. Lee, Ph.D., Adjunct Professor of Physiology in Columbia University. Pp. 615, with 285 illustrations. London: Macmillan and Co., Limited. New York: The Macmillan Co.

fertilisation), and the phenomena of the transformation of energy within the cell, including the production of movements in plants and animals. The general conditions of life are dealt with in a separate chapter, which embraces also a criticism of the theories of the origin of life on the earth, and a discussion of the phenomena and the causes of death.

The nature of stimulation, and particularly the phenomena of the stimulation of unicellular organisms, are expounded at great length. While in general the treatment of this section is fresh and interesting we cannot help thinking that it would be improved by condensation, and especially by the omission of a good deal of matter which convention has assigned to the ordinary text-books of physiology.

In the last chapter, entitled "The Mechanism of Life," an attempt is made to "construct a bridge between the vital phenomena and the vital process, and so far as the present condition of our knowledge allows, derive the former mechanically from the latter." It is hardly necessary to say that this is the most unsatisfactory portion of the book, and although the author grapples manfully with his self-imposed task, the "bridge" which he "constructs" has as many broken arches as the famous structure of the Vision of Mirza. This is inevitable in the present state of our knowledge. And not even the plentiful use of such terms as "biogens," "axial orientation" and "bistons" (even when "expressed by the factor $\frac{A}{D}$ or expanded into the formula

$\frac{a + a_1 + a_2 + a_3 + \dots}{d + d_1 + d_2 + d_3 + \dots}$ ") nor the deftest manipulation of Pflüger's theory of the role of cyanogen radicals in the living proteid molecule, nor the subtlest conjuring with the magic words "assimilation" and "dissimilation" will at present suffice to tell us why the molecules of the relaxed muscle or the resting gland cell slip at the signal of the nervous impulse into the configuration and motions that characterise the contracted muscle and the active gland cell. The bridge is not yet built. We know only dimly the depth and the breadth of the chasm.

METHODS OF STAINING. (a)

It may be thought by not a few that literature in this department of histology is sufficient; but while this might be true a few years ago, it is not so now, for the army of workers in neurological laboratories has increased, there is greater activity in the investigation of microscopic methods, and new results have been reported worthy to appear in an up-to-date text-book. This little volume, therefore, comes to hand very opportunely, and the author and the translator are to be congratulated on its appearance in the English language. It deals briefly with methods of brain section, hardening for preservation, and preparations of models of pathological specimens. It gives directions for all the minutiae of hardening, staining, labelling, embedding, &c. The chief part is devoted to the method of staining, and while the new is amply referred to, the old is also described in so far as it is necessary, and where it has not been entirely superseded by more modern methods. Naturally the methods of Nissl, Golgi, and Ehrlich receive the largest share of attention. We have pleasure in commending this little handy guide-book to those interested in neurological work.

THE GOOD REGENT. (b)

It is good for medical men, if their bent that way lies, to have literary recreations, and when one has known a medical teacher and writer of distinction as such for years, his appearance in a new field of literature as poet, philosopher, or historian is a welcome revelation. In this way we regard the latest venture of Sir

Thomas Grainger Stewart, the President of the British Medical Association, and to many of his old students, and many who did not enjoy that privilege, the appearance of "The Good Regent" must have been a pleasant surprise. The history of the religious life and character which has so peculiarly distinguished Scotland, is naturally well known to the author, and he has dwelt with a fond interest and understanding on the central figure of the drama as he has moved the scenes from place to place. If we might offer a faint criticism, it is this, that there is somewhat of staccato abruptness in the scenic transitions, a want of introduction which those less versed in Scottish history would find helpful to the continuity of the whole conception. This, by the way, Sir Thomas has given us a just conception of the Earl of Moray, Regent of Scotland, and in an agreeable style.

HALLIBURTON'S CHEMICAL PHYSIOLOGY. (a)

"THE rapid advances which chemical physiology has made during the past few years has rendered a good deal of attention necessary in the present edition. The practical exercises are, however, but little modified; the changes introduced there are principally in arrangement; still it has been thought necessary to amplify a certain number of these, particularly in the advanced course. The lessons on the urinary pigments and crystallisation of egg-albumen are entirely new. The main changes in the book will be found in the large text; this has been considerably extended, and the sections relating to the proteids have been entirely re-written."

The above extract from the preface to the present issue of this conveniently-sized and handsomely printed manual contains the author's own account of the new features which the student and critic are invited to examine. As the reputation of the book in its former editions has already been thoroughly established, we will not wait on the present occasion, longer than while saying that Professor Halliburton has done everything necessary to bring the present issue thoroughly up to date. It is really a beautiful as well as reliable scientific manual, and should be in the hands of every student of physiology.

TRANSACTIONS OF THE SOCIETY OF ANÆSTHETISTS. (b)

SINCE Sir Thomas Watson founded the Clinical Society no province of medicine ever offered a more fruitful field for research than that of anæsthetics; and no Society was ever better situated for carrying on the research than the "Society of Anæsthetists."

All sorts and conditions of men pass through the principal London hospitals. They come of every race and from every climate. The anæsthetist meets with the robust dock labourer admitted for an accident, and the weary, worn-out seamstress seeking surgical relief for chronic suffering.

Above all, the great numbers that pass through the London hospitals allow of a tolerably fair estimate of the comparative values of the anæsthetics used.

Let us see how the Society commences its career, and as we open the dainty, well-printed volume before us we regret to find neither a table of contents nor an index; we are left to turn page by page without guidance of any kind.

The opening paper, "On the Addition of Ether Vapour during Chloroform Administration," by Mr. Walter Tyrrell, is a good, practical contribution to the administration of anæsthetics; and the discussion consequent on it brought out a very interesting story of prolonged anæsthesia from nitrous acid by Dr. Flux; the influence of suggestion in causing profound anæsthesia in hysterico-epileptics was freely and ably discussed, and some illustrative cases given by Messrs. Braine, Tyrrell, and Starling.

(a) "Methods of Staining the Nervous System." By Dr. Bernhard Pollack. Translated from the Second German Edition by W. E. Jack, M.D., B.L. Glasgow: F. Bauermeister.

(b) "The Good Regent: a Chronicle Play." By Sir T. Grainger Stewart, M.D., LL.D. Edinburgh and London: Wm. Blackwood and Sons.

(a) "The Essentials of Chemical Physiology: for the Use of Students." By W. D. Halliburton, M.D., F.R.S. Third edition. London, New York, and Bombay: Longmans, Green, and Co. 1899.

(b) "The Transactions of the Society of Anæsthetists." Volume I. 1898. London: The Medical Publishing Company

"Resuscitation in Emergencies under Anæsthetics" is the title of Mr. Wilson's paper, in which we find no mention of the use of oxygen. Of inversion the author writes not very favourably, being influenced by theory, and withal not familiar with Dr. Chisholm's good results from it. Influenced by M. Roger's theory of the "conditions of the vascular system produced by shock," Mr. Wilson does not put much faith in the value of hypodermics of strychnine. We quite agree that if the use of the drug is too long postponed it is of no value. When death is practically present no drug is of any use. But why wait too long? Given in time, however, strychnine is of undoubted value.

"The Dosage of Anæsthetics" is an able survey of our knowledge of the subject by Dr. Waller. We think, however, that too much stress is placed on the apparatus used, and not enough consideration given to the patient and his condition. Three cases of death under anæsthetics were reported by Mr. McCardie. Administering anæsthetics through the nose was the subject of a paper by Mr. Coleman, in which he credits the late Sir B. W. Richardson with being "the first to try in an operation on the mouth the insertion of a tube, connected with a chloroform inhaler, into one nostril." If Mr. Coleman will consult the "Manual of Military Surgery" for the use of the surgeons of the Confederate States, he will find that in 1861-62 the method of chloroforming by the nostrils was adopted by Dr. J. Julian Chisholm, of South Carolina, in order to save the chloroform, as their sole source of supply was that captured from the Federals and the small quantity that ran the blockade.

Space does not allow of a more extended notice; indeed, we have gone beyond the usual limit with this one. We did so, for we felt that the good work the Society is doing should be known, and we think every anæsthetist should familiarise himself with these Transactions. They contain very useful and practical matter, much of which, although not new, is well worth retelling.

There is, withal, a fault the London members appear to be permeated with—an unreasoning fear of chloroform.

ELEMENTS OF ALKALOIDAL ETIOLOGY. (a)

It is always refreshing, and very often highly instructive, to examine the work of a heterodox writer, who has mastered his subject, and knows how to convey his ideas to his readers. Earnest students of the history of the advancement of human thought and human research are well acquainted with the truth of the statement—which to the multitude will always appear a startling paradox—that the great bulk of our existing knowledge is due to the work of heretics, or of those who have been persecuted as such.

In the present instance our author traces disease to the accumulation of necessarily existing alkaloidal poisons—the ash of the combustion of the animal cell. He has earnestly worked out his theory; and, evidently, earnestly believes in it. "As we have seen (he tells us on page 54), the blood necessarily disposes of its poisonous accessories through the various organs of elimination, and consumes them in the circulatory current in contact with the red globules. This being the case, can the blood be regarded as otherwise than toxic?"

On p. 76, he states forcibly the position which the heroes of bacteriological pathology will dispute with most vigour. "But leaving leading germ-pathologists to exploit their new position, we must insist that the phenomena of disease, even to the most essential processes, are possible without the intervention of micro-organisms, bacillary or otherwise."

The position assumed by our author involves too many points of possible or probable dispute for discussion within the limits of a necessarily short review. But we would strongly recommend all earnest students of medicine to examine its contents for themselves. Whether they agree with his conclusions or no, his arguments will give them ample material for examination and reflection.

(a) "Elements of Alkaloidal Etiology, Introductory to the Study of Auto-Intoxication in Disease." By A. M. Brown, M.D. London: Henry Kimpton. 1899.

New Medical and Surgical Appliances.

A NEW URINE TEST CASE.

THE new Urine Test Case devised by Mr. W. Harrison Martindale, Ph.D., is certainly the most compact and complete arrangement of the kind we have yet been privileged to inspect. It is contained in a neat

mahogany cabinet, measuring 6 X 2½ X 4 inches, and the contents comprise all the apparatus and reagents for the qualitative and quantitative examination of urine in respect of albumen, glucose, and urea. These are neatly and firmly packed, so that the case, which is provided with a handle, can be safely carried about without fear of damage.

Every careful practitioner must have experienced the need of a portable apparatus of this kind which facilitates immediate diagnosis in new cases, and it obviates the necessity for taking home, or arranging for the dispatch of, samples of urine for analysis.

The picric acid test, which is the one selected as the test for the presence of albumen, is, on the whole, more convenient, and fully as delicate, as the ordinary method by boiling. If, however, the latter test be preferred, there is a spirit lamp which enables a control estimate to be made by the alternative method.

A little book of instructions, with a supply of charts, complete the equipment which could not well be made more comprehensive. It is sold by Mr. Martindale, of 10 New Cavendish Street, W., at the very moderate price of 17s. 6d.

POCKET CASES FOR DRUGS.

AMONG other novelties of recent introduction by Mr. Martindale we may note (1) a pocket case to carry one dozen nitro-glycerine tablets; (2) a similar portable case to contain three dozen amyl nitrite capsules. These go easily into the waistcoat pocket, and will doubtless be appreciated by anæsthetists and others.

Medical News.

For the Troops in South Africa.

WE are asked to announce that Messrs. Nestlé have received several large orders from the War Office for their Swiss Milk, and Viking Unsweetened Milk, for use of the troops in South Africa.

Messrs. R. Ellis and Son, of Ruthin, have generously offered 10,000 bottles of their well-known brand of soda water for the use of the British troops engaged in South Africa, which will doubtless be greatly appreciated. Messrs. Ellis and Son are now in correspondence with the War Office as to the shipment of this large consignment, which we hope will before long be helping to refresh many of our brave fellows in the Transvaal.

Vital Statistics.

THE deaths registered last week in thirty-six great towns of England and Wales corresponded to an annual rate of 18·7 per 1,000 of their aggregate population, which is estimated at 12,786,832 persons in the middle of this year:—

Birkenhead 13, Birmingham 17, Blackburn 20, Bolton 19, Bradford 18, Brighton 18, Bristol 18, Burnley 20, Cardiff 15, Croydon 15, Derby 13, Dublin 33, Edinburgh 16, Glasgow 19, Gateshead 18, Halifax 12, Huddersfield 17, Hull 20, Leeds 16, Leicester 12, Liverpool 25, London 18, Manchester 21, Newcastle-on-Tyne 16, Norwich 11, Nottingham 20, Oldham 19, Plymouth 20, Portsmouth 16, Preston 19, Salford 21, Sheffield 19, Sunderland 20, Swansea 15, West Ham 13, Wolverhampton 20. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From measles 1.1 in Hull and 1.4 in Birkenhead; from fever, 1.1 in Nottingham and in Sunderland, and 1.3 in Bolton; and from diarrhoea, 1.0 in Sheffield, 1.1 in Liverpool, 1.2 in Salford, 1.4 in Cardiff and in Burnley, 1.5 in Gateshead, 1.6 in Bolton, and 2.7 in Preston. In none of the large towns did the death-rate from scarlet fever or from whooping-cough reach 1.0 per 1,000. The 114 deaths from diphtheria included 57 in London, 10 in Sheffield, 6 in Leeds, 4 in Portsmouth, 4 in Liverpool, and 3 in West Ham. Four deaths from small-pox were registered in Hull, but not one in any other part of the United Kingdom.

Death under Chloroform.

An inquest was held last week at Hornsey on the body of a single woman, æt. 65, who succumbed to the effects of chloroform, administered for the purpose of enabling Dr. Herman to perform an exploratory operation. The chloroform was administered by the family doctor, but breathing suddenly ceased before the examination could be completed, and attempts at resuscitation failed. No information was elicited as to the method of administration employed or as to the amount of chloroform used. The usual verdict was returned.

Patriotic Medical Students.

THE departure of the anatomical porter of Mason's College, Birmingham, to rejoin his regiment, he being a reservist, was an opportunity not to be missed by the medical students of that institution, who turned out and marched through the streets, flags flying, to see him off by train. We regret to see that "one rowdy young medical" had to be removed by three sturdy porters from the railway station, but this was the only untoward incident of a very enthusiastic demonstration.

A Good Analysis at Paris.

DURING September the Paris Municipal Laboratory made 653 analyses of wines, with the result that 139 were judged good, 221 passable, and 196 bad. Of beers 39 were good, 29 passable, and 14 bad. Spirits were declared good in 132, passable in 31, and bad in 23. When we turn to food stuffs proper the result is less satisfactory, for the analyses of milk gave only 121 good, with 102 passable, and 201 (!) bad; while of 73 samples of meat 53 were good, and 20 bad. One never hears much of prosecutions for alimentary adulterations in France, and one wonders what useful purpose is served by these analyses. The mere fact that 201 out of 424 samples of milk were described as bad, shows clearly enough that the delinquents are not seriously dealt with.

Civilian Medical Officers for the Army.

IN order to fill the vacancies in the Royal Army Medical Corps at Woolwich, consequent upon the departure of medical officers in South Africa, recourse has been had to the employment of civil practitioners, of whom the following have been ordered to report themselves to the Principal Medical Officer at Herbert Hospital:—Messrs. C. H. Furnivall, T. Hartigan, E. S. B. Eames, R. L. Jones, A. J. Wernet, T. W. Atkins. Capt. C. E. G. Stalkart, R.A.M.C., has this week joined at Woolwich for duty.

Lectures at the Central London Throat Hospital.

THE usual winter course of lectures at the Central London Throat and Ear Hospital, Gray's Inn Road, is announced, and promises to be interesting. The first lecture is to be given by Mr. Lennox Browne on Monday next, the 30th inst., and will treat of "the recurrence of enlarged tonsils and adenoids after removal by operation," a subject of considerable importance to all practitioners.

The Mortality of Foreign Cities.

THE following are the latest official returns, and represent the last weekly death-rate per 1,000 of several of the populations:—Calcutta 28, Bombay 42, Madras 33, Paris 16, Brussels 15, Amsterdam —, Rotterdam —, The Hague —, Copenhagen 15, Stockholm 15, Christiania 17, St. Petersburg 18, Moscow 24, Berlin 18, Hamburg 16, Dresden 20, Breslau 21, Munich 23, Vienna 17, Prague 20, Buda-Pesth 19, Trieste 25, Rome 13, Turin —, Venice —, Cairo 41, Alexandria 27, New York —, Philadelphia 15.

PASS LISTS.

Royal University of Ireland.

FIRST MEDICAL EXAMINATION.

PASS. Anna E. Adderley, Cath. Univ. and Roy. Coll. Sci.; Lily A. Baker, Roy. Coll. Sci.; John Brady, Univ. Coll., Dub.; Michael Carney, Q. Coll., Cork; John J. Clarke Univ. Coll., Dub.; William M. Crofton, Univ. Coll., Dub.; John Dowling, Q. Coll., Galway; Edward Fitzgerald, Q. Coll., Belf.; Maurice Fitzgerald, Univ. Coll., Dub.; Daniel Gillespie, Q. Coll., Belf.; Marie E. Hayes, Roy. Coll. Sci.; Charles G. Lowry, Q. Coll., Belf.; Jonas Morris, Q. Coll., Cork; Michael J. O'Flynn, Q. Coll., Gal.; Pierce Power, Q. Coll., Cork; John J. Rogers, Univ. Coll., Dub.; Francis C. Sampson, Univ. Coll., Dub.; and David H. Vickery, Q. Coll., Cork.

RECOMMENDED FOR HONOURS.—Lily A. Baker, Botany, Zoology and Chemistry; Michael Carney, Zoology, Chemistry and Physics; John J. Clarke, Chemistry; William M. Crofton, Botany, Zoology, Chemistry, Physics; John Dowling, Zoology; Maurice Fitzgerald, Zoology; Daniel Gillespie, Botany, Chemistry; Marie E. Hayes, Chemistry, Physics; Charles G. Lowry, Chemistry; Michael J. O'Flynn, Zoology; John J. Rogers, Zoology; Francis C. Sampson, Zoology; and Daniel H. Vickery, Zoology.

SECOND MEDICAL.

UPPER PASS.—"Sydney H. G. Blakely, Q. Coll., Belf.; Thomas Carnwath, Q. Coll., Belf.; Robert H. Caughey, B.A., Q. Coll., Belf.; John P. J. Harty, Q. Coll., Belf.; William E. Hayden, Q. Coll., Belf.; Henry M. Johnston, Q. Coll., Belf.; Thomas Killen, Q. Coll., Belf.; John Shipsey, Q. Coll., Cork; James K. Small, Q. Coll., Belf.; William Warnock, Q. Coll., Gal.

Candidates marked thus * are recommended for Honours.

PASS. John D. Buchanan, Q. Coll., Belf.; Alfred A. Chancellor, Q. Coll., Belf.; William Cummings, Q. Coll., Belf.; Peter F. Dolan, M.A. Cath. Univ. Sch. Med.; Roger J. Dwane, Cath. Univ. Sch. Med.; Alfred J. Foote, Q. Coll., Cork; John J. Gillis, Q. Coll., Belf.; Alfred W. Hamilton, Q. Coll., Belf.; Samuel T. Irwin, Q. Coll., Belf.; James W. Killen, Q. Coll., Belf.; James T. McDermott, Q. Coll., Cork; Thomas McFeteridge, Q. Coll., Cork; Francis A. McOstrich, Q. Coll., Cork; Patrick J. Murray, Cath. Univ. Sch. Med.; William F. O'Connor, Q. Coll., Cork; Daniel J. Roffantree, Cath. Univ. Sch. Med.; Charles E. Saffern, Q. Coll., Belf.; Thomas H. Saffern, Q. Coll., Belf.; Andrew T. Swan, Cath. Univ. Sch. Med.; John Thompson, Q. Coll., Belf.; Margaret Toner, Q. Coll., Belf.; James W. A. Wilson, Q. Coll., Belf.

The examiners have recommended that the following candidates be adjudged to have passed the undermentioned examinations.

M.B., B.Ch., and B.A.O. Examinations.—Upper Pass: Isaac M. Byers, (a) John E. Clements, Belf.; James Good, William Hartnett, Cork; (a) William M. Hunter, (a) David Kernohan, Q. Coll. Belfast; Wm. Lapsley, Q. Coll., Cork; Thos. J. McDonogh, B.A., and (a) Bernard A. O'Flynn, Cath. Sch. Med.; and (a) John W. West, Q. Coll., Belf.

PASS.—Annie W. Crawford, Arthur W. Crawford, Henry L. Craig, Emily M. Crookes, and John H. Davis, Q. Coll., Belf.; Bertram R. Dinnis, Q. Coll., Cork, and Univ. Edin.; Hugh Donnelly, Q. Coll., Belf.; Frances A. Dreaper, B.A., Cath. Sch. Med.; David Finnegan, John R. Gillespie, M.A., Galbraith H. Grills, Samuel Hill, Alexandrina C. Huston, and George Jefferson, Q. Coll., Belf.; Charles Kidd, Q. Coll., Gal., and Sch. of Med., Edin.; Kathleen F. Lynn and Samuel M'Cann, Cath. Univ. Sch. Med.; Edwin W. S. Martin, Douglas C. Moore, and Patrick J. Morgan, Q. Coll., Belf.; Thomas F. O'Keefe, Q. Coll., Cork, and Cath. Univ. Sch. Med.; Patrick M. Quinn, Cath. Univ. Sch. Med.; James Ritchie, Q. Coll., Belf.; Frederick Ryan, Cath. Univ. Sch. Med.; and Joseph J. Waters, Q. Coll., Gal., Cath. Univ. Sch. Med., and Sch. Med., Edin.

M.B. Degree Examination. Ignatius J. Flynn, M.B., B.Ch., B.A.O., Cath. Univ. Sch. Med.; Thomas Houston, B.A., M.B., B.Ch., B.A.O., Q. Coll., Belf., and Robert Watson, M.B., B.Ch., B.A.O., private study.

(a) Indicates that the candidate may present himself for the further examination for honours.

Royal College of Surgeons, Edinburgh.

AT the annual meeting of the College on the 18th inst., Dr. James Dunsmure was unanimously elected President for the ensuing year, and the following gentlemen, having passed the requisite examinations, were duly elected Fellows of the College:—

Francis Horatio Amner, L.R.C.S.E., Tongkah, Siam; Nathaniel Thomas Brewes, F.R.C.P.E., Arthur Mayers Connell, M.R.C.S. Eng., George Aubrey Jelly, M.R.C.S. Eng., Robert Holbourne William Johnson, L.R.C.S.E., John Norman Macleod, M.B., C.M. Glasg., Robert Henry Parry, L.R.C.S.E. Glasg., Henry Carden Pearson, M.B., C.M. Edin., John Connell Ramsay, L.R.C.S.E., Donald Ferdinand Schokman, L.R.C.S.E., John William Struthers, M.B., Ch.B. Edin., and Andrew Hutton Watt, M.B., C.M. Edin.

WHERE THE CHAMPAGNE GOES.

ACCORDING to a recent report the total number of litres of champagne exported attains the respectable dimensions of close upon twenty millions, representing about £3,500,000. England stands first on the list of customers with 10,600,000 bottles, then Belgium with 2,778,700, Germany with 1,859,200, and the United States (with Canada) 1,419,000. Russia only absorbs 498,500 bottles, but these are of the very first brands, and Holland follows closely with 468,400. Sweden buys 259,200 bottles, Denmark 188,700, Austria 152,300, Switzerland 141,400, Italy 129,700, Australia 125,600, Norway 108,200, and India 100,000 bottles. The price *en gros* of the wine is four or five francs, showing what an enormous profit is made on champagne when sold *en detail*.

SPEES.—Since 1882 venereal disease in the British army has increased 15 per cent., as shown by the official records.

IRISH POOR-LAW MEDICAL OFFICER'S RESIGNATION BEFORE SUPERANNUATION.

A. A. asks to be informed if it is necessary for a Poor-law medical officer to resign before applying for superannuation allowance, and if so, please state authority for your answer.

[The resignation must be a completed transaction before the guardians can consider the question of pension. It is essential that a month's notice should be given by a guardian to move the grant of a pension, but it is not essential—as was formerly supposed—that the resignation should be handed in at same time. It may be withheld until five minutes before consideration of the motion, and may, therefore, be withheld altogether if the motion does not seem likely to pass.—Ed.]

I. V. R. (Birmingham).—Our correspondent cannot improve upon the course which he has decided to adopt.

OMEGA.—The disease depends upon the toxin generated by the action of the bacilli.

THE LATE SIR WM. GULL ON "DON'TS."

In his recent address at Mason University College, Professor Chiene repeated, for the benefit of his audience, the oft-quoted "don'ts" accredited to the late Sir Wm. Gull.—Don't talk to your patients about your patients. Don't hesitate to ask for a consultation if you are in doubt. Don't refuse a consultation if a patient desires it. Don't give two prescriptions, with the remark, "If the one fails try the second;" it savours of experiment, and no patient likes to be the subject of experimental research. Be silent when in doubt. Take careful notes of your cases. Have a hobby as a means of losing time wisely.

NUCLEUS.—It is possible that a plastic operation would be of service.

SPASM OF LEVATOR ANI.

H. S. M. asks for information about the treatment of spasm of the levator ani. Cause of the disease in this case unknown, and heat the only thing of use.

Meetings of the Societies and Lectures.

WEDNESDAY, OCTOBER 25TH.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20 Hanover Square, W.).—8.30 p.m. Informal Exhibition of Cases. 5 p.m.—Ordinary meeting.

HUNTERIAN SOCIETY.—8.30 p.m. Clinical Evening. Cases will be shown by Sir H. Beevor, Dr. F. J. Smith, Dr. Ross, Mr. Barnard, and other Fellows.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square).—4.30 p.m. Dr. Eddowes: Sycosis (Post-Graduate Course).

THURSDAY, OCTOBER 26TH.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20 Hanover Square, W.).—8.30 p.m. General Meeting. Dr. J. I. Murray (President): A Retrospect and a Forecast.

NEUROLOGICAL SOCIETY OF LONDON (Medical Society's Rooms, 11 Chandos Street, W.).—8.30 p.m. Clinical Meeting. The following cases will be shown:—Dr. F. E. Batten: Unusual Form of Muscular Atrophy.—Dr. T. Buzzard: Myasthenia Gravis.—Dr. J. Taylor: Myopathy of Landouzy (Déjérine Type).—Dr. W. Harris: Myopathy of Landouzy (Déjérine Type), and other cases.

FRIDAY, OCTOBER 27TH.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8.30 p.m. Clinical Evening. The following cases will be shown: Dr. Guthrie: Cerebellar Symptoms relieved by Trephining.—Mr. G. R. Turner: (1) A Case of Actinomycosis in Process of Cure; (2) A Case of Ostitis Deformans.—Mr. J. Jackson Clarke: A Patient in whom Kraske's Operation was performed (with specimen).—Mr. Watson Cheyne: Old-Standing Dislocation of the Hip, with Fracture of the Acetabulum, reduced by Operation.—Other cases will be shown. Patients will be in attendance at 8 p.m.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION (11 Chandos Street, Cavendish Square, W.).—4 p.m. Meeting.

MONDAY, OCTOBER 30TH.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—5 p.m.

Mr. Lennox Browne's lecture on "The Recurrence of Enlarged Tonsils and Adenoids after removal by operation."

Vacancies.

Bethlehem Hospital, London.—Two Resident House Physicians. Apartments, complete board, and washing provided, and an honorarium at the rate of £12 12s. per quarter. (See advt.)

Birmingham City Asylum.—Senior Medical Officer unmarried. Salary £150 per annum.

Carrickmacross Union.—Medical Officer. Salary £100 per annum, together with the Vaccination and Registrations Fees. Application to Clerk of Union.

County Asylum, Prestwich, Manchester.—Assistant Medical Officer, unmarried. Salary to commence at £125, with board, apartments, and washing.

County Borough of Great Yarmouth.—Medical Officer of Health, Medical Officer for the Borough Isolation Hospital, and Port Medical Officer of Health. Salary £400 a year. Apply to the Town Clerk, Town Hall, Great Yarmouth.

County of York, West Riding Asylum, Wakefield.—Junior Assistant Medical Officer. Salary commencing at £100, with furnished apartments, board, washing, and attendance.

Hospital for the Insane, the Coppice, Nottingham.—Assistant Medical Officer, unmarried. Salary £150 per annum, with apartments, board, attendance, and washing.

Manchester, Chorlton-upon-Medlock Dispensary.—Resident House Surgeon, unmarried. Salary £120 a year, with furnished rooms and attendance.

Nottingham General Dispensary.—Senior Resident Surgeon, unmarried. Salary £180 a year, increasing by £10 annually to £200. Special arrangement for board, &c.

Parish of Fulham.—Assistant Medical Superintendent for the Infirmary, St. Dunstan's Road, Hammersmith, unmarried. Salary commencing at £120 per annum, with board, apartments, &c.—Applications to the Clerk, 75 Fulham Palace Road, Hammersmith, W.

Pontefract General Dispensary and Infirmary.—Resident Medical Officer. Commencing salary £130 per annum, rooms, fire, lights, and attendance.

Stoke-upon-Trent Union.—Resident Medical Officer for the Workhouse. Salary commencing at £130, with board, washing, &c.—Applications to the Clerk, Union Offices, Stoke-upon-Trent.

Appointments.

BAILEY, REGINALD THRELFALL, M.B.C.S., L.R.C.P. Lond., Resident Medical Officer to the (Lock Dept.) Royal Infirmary, Liverpool, and House Surgeon to the Ophthalmic Laryngological and Aural Departments.

COOMBE, RUSSELL, M.A., M.D. Cantab., F.R.C.S. Eng., M.R.C.P. Edin., has been appointed for duty in connection with the medical charge of troops at Exeter.

DAVIDSON, W., L.R.C.P., L.R.C.S. Edin., Medical Officer for the Sixth Sanitary District of the Beverley Union.

DUNN, J., F.R.C.S. Edin., L.R.C.P., L.F.P.S. Glasg., President of the Halifax and District Medical Society.

EVANS, J., M.R.C.S., Medical Officer for the Children's Homes of the Cardiff Union.

HUNTON, R., M.B., C.M. Edin., Medical Officer for the Hartlepool and Stanton Sanitary District of the Hartlepool Union.

MORSHEAD, E. G. A., M.D., L.R.C.P. Lond., M.R.C.S., an Honorary Medical Officer of the Royal Surrey County Hospital, Guildford.

MUIR, J. C., M.B. Camb., M.R.C.S., Second Resident Assistant Medical Officer for the Crumpsall Workhouse, Manchester.

OLIVER, C. P., M.D. Lond., L.R.C.P., M.R.C.S., Medical Officer of Health to the Maidstone Urban District Council.

PERNET, GEORGE, M.B.C.S., L.R.C.P., Honorary Pathologist to the Hospital for Diseases of the Skin, Blackfriars.

SISSONS, A. T., M.B., B.Ch. Vict., Junior Resident Assistant Medical Officer for the Crumpsall Workhouse, Manchester.

SMITH, W. E., M.B., C.M. Edin., has been appointed President of the Central Board of Health for South Australia.

TROTTER, EDWARD, M.B., Ch.B., House Surgeon to the Hospital for Women and Children at Leeds.

WINDSOR, C. W., M.D. Camb., L.R.C.P. Lond., M.R.C.S., Medical Officer for the Workhouse of the Royston Union.

Births.

ANDRE.—On October 20th, at Sidlesham near Chichester, the wife of J. E. F. Andre, M.R.C.S., L.R.C.P., of a son.

COCK.—On October 18th, at 1 Porchester House, London, W., the wife of F. William Cock, M.D., of a son.

FAIRWEATHER.—On October 18th, at "Glenesk," Wood Green, N., the wife of D. Fairweather, M.A., M.D. Edin., of a son.

REECE.—On October 16th, at Addison Gardens, London, W., the wife of Richard J. Reece, M.A., M.D., of a son.

STOCKEN.—On October 17, at Winchester House, Ealing, the wife of Leslie Maury Stocken, M.R.C.S., L.R.C.P., of a daughter.

Marriages.

BRADFORD-ROBERTS.—On October 17th, at St. Phillip's Church, Adderley Edge, Manchester, John Rose Bradford, M.D., F.R.S., to Mary (May) daughter of the late Thomas Foulkes Roberts, J.P.

Deaths.

PALMER.—On October 21st, at Lancaster House, Lincoln, E. win C. Palmer, M.A., M.B., B.Ch. Cantab., aged 34.

The Medical Press and Circular.

THE AFTER-EFFECTS OF REMOVAL OF THE APPENDAGES AND OF REMOVAL OF THE UTERUS. (a)

By J. FURNEAUX JORDAN, M.B., F.R.C.S.,

Surgeon to the Birmingham and Midland Counties Hospital for Women.

At the Women's Hospital in Birmingham we have, like all other hospitals, an annual meeting at which the report of the work done in the in-patient department is next, perhaps, to the balance-sheet, the most important document produced. In this report, rightly enough, no mention is made of the previous history, or of the condition at the time of entrance, or of the after history of the patients under our care; but great stress is laid on the mortality rate. Is it under 5 per cent. or over 5 per cent.? I have never yet come away from this meeting without feeling how little light is thrown on our work by this necessarily bare report. At the time of drawing up this report, it is impossible to do more than put on record the immediate result of the operation. I am venturing then to-night to dip a little deeper into the notes of my cases to review them right up to date, to state their present condition, and to point out what lessons I have learnt from this after history of my cases.

The great difficulty in bringing the reports up to date is that some of the patients disappear altogether from observation. The poor people in the crowded parts of a Birmingham and the towns of the Black Country think far less of moving house than we or our wives do of a spring cleaning. In spite of this however—thanks largely to the Post Office—I have been able to trace all but two of them. Another drawback to such a report is that I was not born ten years earlier; none of my cases can present a post-operative history of more than a few years, since I did not begin operative gynaecological work till the beginning of 1893. There are, of course, many cases in which after recovery from an operation the patient remains, as far as the effects of the operation are concerned, in a stationary condition, but it is distinctly different in cases in which the operation involves removal of the uterus or its appendages. It is, therefore, the post-operative progress of these cases that I wish to consider to-night.

I have tabulated my cases of removal of both appendages for disease up to September of last year; the shortest after-history is thus of twelve months' duration. The number of cases operated upon is 43, of these 3 died as a result of the operation. These three deaths followed operation for removal of double pyosalpinx, and were due in each case to perforation of the bowel, and peritonitis on the second or third day after the operation. The total number of cases of pyosalpinx operated upon is 20, the mortality, therefore, of these

cases is exactly 15 per cent. None of the other cases have died. It is impossible in a table to go into minute details as to the severity of the disease. I have indicated the main conditions, and you can see that some of the operations were most difficult, the appendages being buried in adhesions, that others were easy, adhesions being slight or absent, and that between the two extremes were operations of varying severity. Of the 40 cases which recovered, I have got full information of the after progress in 38. Two of them I have been unable to trace. Of these 38 in the table, the report in 35 cases is founded on a personal interview held within the last month, in two cases the report is founded on a written statement sent me by the patient in reply to my questions. One case died two months after the operation from exhaustion due to advanced tuberculous disease. We therefore have the after-history of 37 cases, and inquiries were made as to the following points:—

The severity and duration of the symptoms due to the production of the menopause, and their occurrence at fixed periods.

The continuation of menstruation after operation and the occurrence of vicarious menstruation.

The effect of the operation upon the body-weight,

The effect upon the marital functions.

The condition of the scar of the abdominal incision.

The state of the general health, and the capacity for work.

I made a personal examination of the abdominal incision, and, when I thought it necessary a bimanual examination of the pelvis. I shall neither spend your time nor weary you by reading all the details of Table I. I will try and present you with a summary.

First, then, as regards the severity and duration of the climacteric symptoms.

Taking the latter first I can only give the duration in twenty-four cases; in the other cases the symptoms are still present more or less. The duration varies between five-and-a-half years and a year. The average duration in the twenty-four cases is about three years. In examining into the severity of the symptoms I divide the cases into four classes—very severe, severe, moderate, and slight. By "very severe" I mean that the patient not only suffered from heats and flushes and attacks of giddiness, &c., but was occasionally laid up by them and prevented from working. By "severe" I mean that the patient felt them badly, was very distressed during their occurrence, but was never actually laid up by them. By "moderate" I mean that the symptoms were troublesome more than distressing, and were less frequently felt than in "severe" cases. By "slight" I mean that the patient was very little troubled by them.

Three patients, 8.1 per cent., suffered very severely; twelve, 33.2 per cent., severely; ten, 26 per cent., moderately; and seven, 19.4 per cent., slightly.

The average age, at the time of operation, of those who suffered very severely was 27, of those who suffered severely the average age was 31, of those who suffered moderately 34, of those who suffered slightly, 32. On the whole we can draw the conclusion that the younger the patient the greater will be her sufferings from an artificial menopause. A noticeable feature is the youthfulness of the patients—thirteen of them, i.e., nearly a third, were under 30 at the time of operation. In ex-

(a) Read at a meeting of the British Gynaecological Society on October 12th, 1899.

planation of this we must remember that many of these cases—the majority of the pyosalpinx cases and many cases of thickened and occluded tubes with adherent cystic ovaries—are due to gonorrhœa. In the poorer classes it is the young child-bearing women who contract this disease from their husbands. Of the thirteen cases under 30 years of age seven suffered from pyosalpinx, one from thickened occluded tubes with cystic ovaries, and five from cystoma of both ovaries. This condition, which I have briefly described as “thickened occluded tubes with cystic ovaries” is one which I have no doubt you all know as well or better than I do. The patient usually has a history of old gonorrhœa, the tube is thickened and softened, the ligature cuts through it, the contents are a grumous muco-purulent fluid, and you would not be surprised if you found pus. The tube is adherent to a large cystic ovary, the two forming one swelling adherent to broad ligament, uterus and often bowel or mesentery.

To come back to my table, in seven cases the symptoms were distinctly worse every four weeks, and in two cases occurred only every four weeks. As regards the continuation of menstruation after operation I find that it ceased entirely in twenty-seven cases—i.e., in 73 per cent. In ten cases menstruation occurred after operation. The particulars are as follows:—

No. 10. Menstruated regularly for six months after operation; the quantity lost diminished at each successive period.

Nos. 11 and 12. Menstruation continued regularly, profuse loss and great pain until relieved by vaginal hysterectomy.

No. 14. Menstruated every three months for a year after operation.

No. 19. Menstruated once, three months after operation; six months after operation had an attack of epistaxis, which was repeated at the ninth month, and finally in another three months had hæmorrhage from the bowel.

No. 21. Hæmorrhage from a small pile every four weeks, never at any other time.

No. 22. Menstruated every three months for two years after operation.

No. 34. Menstruated for nine months after operation, but irregularly.

No. 36. Menstruated once, three months after operation.

No. 37. Menstruated every month since operation twelve months ago, the quantity lost is diminishing.

In all the cases in which menstruation continued after removal of the appendages there were very dense adhesions, and it is quite probable that some ovarian tissue was left behind, which went on ovulating for some time until it became used up as it were. Especially is this so in the two cases, in which a double pyosalpinx was removed by post-vaginal cœliotomy. In all the cases but one, No. 37, the symptoms of the menopause were slight, and I am therefore not sure that the patients were any the worse off for a slight persistence of menstruation. They were, as it were, let down easily.

In two cases, Nos 11 and 12, the menstruation continued without any change for the better until relief was afforded by a vaginal hysterectomy.

In No. 11, after removing from dense adhesions a right tubo-ovarian abscess, I found the appendages of the left side so strongly adherent that I felt at the time I had not removed them entirely. Her condition was so bad after the operation that she begged me to do something to relieve her. I waited two years to see if there was any improvement, and then did a vaginal hysterectomy, the most difficult one without exception that I have ever done. I had to cut the uterus out of a mass of adhesions, so dense that it was absolutely immovable. The relief has been very marked, and she would, as she says, be comfortable if it were not for chronic bronchitis, as a result of which she has a hernia of the scar in the abdominal wall. This I have operated upon once, but owing to her persistent cough it is giving way again.

In No. 12, too, the appendages were very adherent, so much so that the hæmorrhage on separating them was profuse, and led me to use a drainage tube. She, too, got a hernia of the scar four months after operation, which I operated upon immediately with a permanently

good result. Twelve months ago she contracted gonorrhœa, and following this her menstruation became more profuse and acutely painful. I did a vaginal hysterectomy for her six months ago, and already she is much better in health. I have gone more fully into these two cases because they perhaps raise the question whether I ought straightway to have done a vaginal hysterectomy, or even the radical vaginal operation. Discussion on this question I will leave for a minute till I speak of the lessons to be learnt as a whole.

As regards the effect on the bodily weight, in ten cases there was a distinct increase, in nine a slight increase, in thirteen no effect at all, and in three cases a decrease. Of these three, one is getting into a condition of chronic melancholia, one suffers from phthisis, and the cause of the decrease in the third case I cannot explain. It is difficult to speak positively as to the effect on the marital functions. The great majority at once replied that it had made no difference; of the others pain on coitus has persisted in three cases, in two cases the desire for coitus has disappeared. Three of them said that they never cared for it and were just the same now. One of the three cases in which pain has persisted is No. 11, already fully referred to. Another, No. 30, had a sharp attack of peritonitis after the operation and was in bed ten weeks. On examination I found the uterus tender and very slightly movable. There is no doubt that it is to a considerable extent adherent to neighbouring viscera. In the third case, No. 31, I cannot discover the cause of the pain.

We come now to the progress of the scar in the abdominal wall.

In two cases, 4 and 16, there is a little stretching and thinning in the lower part of the incision. It is quite probable that without great care a hernia will form in these cases. A drainage tube had been used in No. 4. No. 10, in which also a drainage tube had been used, developed a hernia in three months, but since I operated upon her four years ago there has been no sign of any recurrence. Nos. 11 and 12 I have already referred to. No. 28 has had a persistent sinus ever since the operation and I have no doubt that in time a ligature will come out or be removed. In the other 31 cases, i.e., in 86 per cent., the scar has never given any trouble and shows no sign of weakness.

Lastly, as regards the general condition of the patient and her capacity for work, I find that, often after a stormy time, good and even robust health has come back to her. I have in many cases put the exact words of the patient into my table, if not in her own words, I have endeavoured briefly to give you an idea of her condition.

Are the results, on the whole, as good as one would wish? Not quite, for I can see now how I might have done better in some of the cases. It is not the final results that are unsatisfactory, it is the intermediate amount of suffering. We must bear in mind, though, that in these cases where adhesions are the rule, it would be foolish to expect no pain or trouble after convalescence. Adhesions and inflammatory deposit round the stump may act for some time as a source of irritation, and may even help in producing post-operative menstruation. Although my earlier cases were free from acute peritonitis after operation, yet I had distinctly more trouble in the after-treatment than I have now. This was probably due to the fact that I did not then carry out the principles of asepsis as thoroughly as I do now.

The cases of hernia of the scar are all among the earlier numbers, for I drained more frequently then, and with a glass tube, than I do now. I believe my cases of pyosalpinx which died would have lived if I had opened and drained them freely by posterior vaginal cœliotomy. I reported a few cases treated by this route in the *British Medical Journal* a few months ago, when I said that in cases of long duration, in which the pyosalpinx, or an abscess communicating with it, can be felt filling up Douglas' pouch, the operation to be preferred is incision and drainage by vaginal cœliotomy. Further experience has only confirmed me in this opinion. In removal of pyosalpinx by the abdominal route it is necessary sometimes to drain. Would not this be better

carried out by incision into Douglas' pouch from the vagina than by a glass tube in the abdominal incision? We should then do away altogether with the chance of hernia.

In cases of bilateral suppuration in the appendages, unless there is co-existing marked disease of the uterus, I should certainly not remove the latter organ. Severe cases of double pyosalpinx or tubo-ovarian abscess can be treated as I have already indicated, by the vaginal route without sacrificing the uterus. Removal of the uterus to make a way for the appendages is, under ordinary circumstances, unjustifiable. I recognise that twice I have had to perform vaginal hysterectomy after a previous removal of the appendages, and I grant that in No. 11 I should have had a better result if I had done a vaginal radical operation at first, not, however, because of any disease of the uterus, but because, with her chronic bronchitis, it would have been better to sacrifice the uterus in order to make a way to the very adherent appendages, than to expose her to the probability of a ventral hernia. In the second case the patient contracted a gonorrhœa, subsequently to the original operation.

I operate less frequently than I did for inflammatory diseases of the appendages, for I am more persistent in insisting on rest; unfortunately in many cases one is compelled in the end to operate in order to render the patient capable of doing her necessary work. In spite of the severity of the symptoms of the menopause I have been struck by the almost universal restoration to health in these cases. With this return of health comes a corresponding capacity for work. Unfortunately, coincident with this is inability of the woman any longer to bear children. In view of this we have already begun to be more conservative in our operations, preserving whenever possible the appendages of one side, or if not the entire appendages then sufficient to give the woman a chance of becoming pregnant. These cases do not enter into the scope of my paper to-night, pleasant thought it would be to dwell upon them. At least, I may say this, that this conservative spirit, preserving what is healthy, sacrificing what is harmful, has already caused a considerable diminution in the number of cases of removal of the appendages for chronic salpingo-oophoritis. Everything that will tend still further in this direction should engage our earnest attention, and it is for that reason that I think we cannot value too highly Mr. Taylor's recent contribution on the treatment of gonorrhœal salpingitis. If we can succeed, as he has succeeded, we shall still further reduce our number of cases of "removal of the appendages." Another thing, too, which will, I think, tend to render the post-operative time more tolerable is the adoption of the vaginal route in suitable cases. I cannot compare the results of the two routes to-night, for nearly all my cases operated upon by the vaginal route have been either for the removal of disease of one side only, or are too recent to present an after history. The more I use this route the better I like it, and the less troublesome do I perceive the after history to be.

One other word I wish to add is this, that we see to it that the patients after these operations get good advice and treatment during the artificial menopause. Two or three of those who suffered most had had little or no treatment. Especially does this apply in the tuberculous cases. With one exception they have done well, but have required constant constitutional treatment. The exception never pulled up, but slowly sank two months after operation.

To sum up, then:

The final result in cases of removal of the appendages for inflammatory diseases is uniformly good.

The severity of the artificial menopause is most marked in young women.

The mortality in severe cases of pyosalpinx treated by abdominal section is higher than one would wish.

The use of the drainage tubes involves a weak spot in the scar.

The likelihood of leaving behind some portion of ovarian tissue is great in cases of very dense adhesions. The effect of this passes off in time.

If the appendages are fully removed, menstruation ceases entirely.

The necessity for, and the advantages to be derived from, removal of the uterus will rarely occur.

I may now add—

Be as conservative as possible, especially in young women, and in "conservative" I include not only operative, but also non-operative measures.

Treat the severe cases of pyosalpinx, if possible, by the vaginal route.

Do not drain unless absolutely compelled to, and then consider the possibility of draining by the vagina.

Do not get disheartened if the patient does not get the full benefit of the operation for some little time.

We come now to a consideration of the cases of myoma for which I have either done a hysterectomy or removed the appendages. I have done one or other of both of these operations on twenty-four patients with myoma of the uterus. Details of the cases are given in Table No. II.

I removed the appendages seventeen times, but from two of these seventeen I subsequently had to remove the uterus.

I did a hysterectomy in the other seven cases, but in one of them the appendages had been previously removed by another surgeon.

No. 1 of the cases in which I removed the appendages died the day after operation with symptoms of hæmorrhage, but I was unable to get a post-mortem examination.

One of my cases of hysterectomy died. This case I shall refer to later on, since it taught me a lesson I shall, I hope, never forget.

The chief points I wish to investigate are:—

(a) The effect on the myoma of removal of the appendages.

(b) The severity of the menopause following this removal as compared with—

(c) The severity of the menopause following hysterectomy.

(d) The general health of the patient subsequent to the operation.

(a) The effect on the myoma of removal of the appendages: Since one of the cases died there are sixteen into whose subsequent history we can examine.

You will see that I had to perform hysterectomy later on in two of these cases, but in one (No. 2) it was, I think, a mistake to remove the appendages. The patient, at 56, suffered intense pain from a myoma at the back of the uterus, which was almost as hard as a stone. The pain on defecation kept her in a condition of chronic constipation and its attending discomforts. There was no hæmorrhage. I might have known that removing the appendages would have no great effect on such a fibroid. Although it diminished slightly in size for nearly three years, yet in 1896 the uterus as a whole began to enlarge, the pain got worse, and I thought it best to remove it entirely. This I did on December 4th, 1896, and found not only the posterior hard myoma, but a largish interstitial one, becoming submucous, in the body of the uterus. Whether this was present, in embryo as it were, at the time of the first operation, I cannot say.

The other case in which I had to do a second operation was No. 11. The fibroid was a large single one, reaching some way above the umbilicus. The patient was very anæmic from the hæmorrhage. For a few months the tumour diminished in size and the hæmorrhage ceased, but then it began to grow again rather rapidly accompanied by severe hæmorrhage. I then did an abdominal hysterectomy, for which she is very much better, although she has had a great deal of pain. With the exception of these two cases, the effect of removal of the appendages has been most satisfactory. The tumour has disappeared entirely except in two cases where it has hardly had time to undergo this process, and in these two, Nos. 23 and 24, it is distinctly smaller.

(b and c) The severity of the menopause following removal of the appendages: I find that the sufferings of the artificially created menopause are here much less on the whole than in cases of removal of the appendages for disease. But then compare the average age of the

two classes of cases. In the latter it was about 30, while in these cases of myoma it is 37.5. The menopause following hysterectomy is a little less severe than in cases of removal of the appendages, but again the average age of the patients at the time of operation is higher than that of the patients who underwent the operation of removal of the appendages, it is as high as 40. On looking over both tables I cannot help noticing that, as a rule the younger the patient the more she suffers from the artificial production of the menopause, and since the difference in the severity of the symptoms between the cases of hysterectomy on the one hand, and the removal of the appendages on the other hand, is not any more marked than the difference between the average ages would lead you to expect, I cannot put down the comparative immunity of the hysterectomy cases from severe symptoms to the fact that the ovaries were left behind instead of being removed. I think it is of the utmost importance that we should find out for certain if, taking all the cases of hysterectomy, the patients suffer less after the operation than they do after removal of the appendages. I wish that my cases were more numerous so that I could speak with more certainty. At the same time, I think that, if every operating gynaecologist were carefully to place on record the after condition of all his cases, we should not be long in arriving at a definite conclusion. Possibly it would be different to mine, viz., that the variations in the severity of the symptoms are due mainly to the relative ages of the patients. Certainly I do not see that the difference is such as to warrant us bringing forward the preservation of the ovaries as a strong argument in favour of hysterectomy. I equally certainly believe, though for other reasons, that in some cases of myoma, hysterectomy will give us a better result than any other operation. I recognise that there are cases in which the artificial menopause is felt slightly in young women and severely in older ones. These, however, are exceptional, and we must always bear in mind the many conditions which influence the course of the menopause, as the degree of susceptibility of the nervous system to stimuli, the surroundings and the habits of the patient, the original cause of the illness and the continuance or not under treatment, judicious or otherwise.

(d) The general health of the patient after operation: On the whole the final result is very good, with the exception of Nos. 3 and 4 they are all in excellent health, and express themselves as feeling better than they have been for some years past.

From a consideration of these cases, and of the cases I have not operated upon, I have come to one or two conclusions as to the treatment of myoma of the uterus.

First, I find that cases do occur in which no operation is immediately called for, which under the continuous administration of ergot and hydrastis combined with rest, may be safely kept under observation for some time, provided always that they do not steadily increase in size.

Secondly, that there are cases which distinctly call for removal of the appendages in preference to hysterectomy. Every now and then we meet with cases where the hæmorrhage has been so severe that the patient is absolutely blanched, where her life has been placed in jeopardy from the hæmorrhage, she lies in bed, white as a sheet, with a small quick pulse, and so feeble that she can hardly speak or move, certainly raising her up will probably cause her to faint. I have had three such cases. Nos. 14, 16, and 24. However skilfully, or by whatever method, a hysterectomy may be done, and however favourable the conditions are, it takes longer, and inflicts more shock upon the patient than removal of the appendages. The extra time and the extra shock, which in an ordinary case will not affect the ultimate result, may in these blanched and almost bloodless patients I have referred to, be just the last straw that breaks the camel's back. In Nos. 14 and 24 I removed the appendages and the result has been even better than I expected, in No. 16, because the tumour was not quite so large, and was situated more in the pelvis than the abdomen, I did a vaginal hysterectomy. I had to slit up the uterus and remove the tumour in pieces and finally complete the

removal of the uterus. I did it fairly quickly, she lost no blood at the operation, and I took every possible precaution against shock, but she never rallied from the operation, dying the same afternoon. I shall never, if I can possibly help it, do hysterectomy again in cases of this kind. Thirdly, for large, unwieldy tumours, dangerous from their very size as much as anything else, and for tumours blocking up the pelvis, rendering life miserable from intrapelvic pressure symptoms I believe hysterectomy is the treatment. I have had, I think, an undue proportion of these intrapelvic fibroids. The operation is not an easy one, but it is well worth all the trouble involved since the relief to the painful symptoms is immediate and complete. This hysterectomy is, I think, done most easily by the combined method, and in mentioning this I do not wish in any way to raise the question as to the choice of the abdominal or vaginal route. To my mind the route does not enter into this question. In doing a hysterectomy unless you leave a subperitoneal stump you are obliged to open the vagina into the abdomen. In the combined method you deliberately do all you can from the vagina, cleansing the vagina easily, and separating the vaginal attachments of the uterus with the greatest ease, and if possible ligaturing the uterine arteries and opening the anterior and posterior peritoneal pouches. Having done all this extra-peritoneally you can easily complete the removal of the tumour from the abdomen.

Lastly, for small myomata demanding interference from their rate of growth, from the hæmorrhage and from the pain I confess frankly that I should hesitate between vaginal hysterectomy and removal of the appendages. I think I should be guided by the stoutness of the patient or by the capacity of the vagina, a stout patient leading me to prefer the vaginal hysterectomy, a small vagina leading me to prefer removal of the appendages. Each case must be judged for itself, it being impossible to lay down any hard and fast line.

Before concluding this consideration of the effects of removal of the uterus, I must refer to three cases in which I have been compelled to perform vaginal hysterectomy for intractable uterine hæmorrhage. The hæmorrhage had only been slightly relieved by curetting, and no treatment that I could think of had the slightest effect on it. The uterus in each case was enlarged, apparently by a general fibrous thickening of its wall. In each of these cases I left the ovaries alone, but they have all three suffered, two of them very severely, and one moderately, from the menopause, but now four years, two years, and eighteen months respectively since their operations, they are over the worst of their troubles. The two who suffered very severely were 23 and 27 years old, the third one was 43. I fail, therefore, to see that if you remove the uterus you save a woman from all trouble by leaving the ovaries. I would save the ovaries by all means if they can help a woman towards ordinary menstruation or child-bearing, but that I ought to prefer to remove the uterus rather than the appendages in a case of myoma, because the woman will suffer less from the former operation than from the latter; I will not say I do not believe, but certainly my own experience does not justify me in believing. I have already indicated what I believe to be the operation best suited to each case, and while believing that a large number, if not the majority, of cases are best and soonest cured by hysterectomy, yet I hold that there are cases which can be best and most safely, if not most quickly, cured by removal of the appendages.

Lastly, there is one case which I overlooked until too late to insert in the table, but which would render my results incomplete if left out. On September 14th, 1897, I removed the appendages in a case of myoma, reaching about half way to the umbilicus, growing rapidly and causing profuse menorrhagia. She went on very well for about thirteen months with no hæmorrhage and diminution in size of the tumour, when she became insane and committed suicide just about this time last year. Whether the insanity was a case of *post hoc propter hoc*, I cannot say. The suicide should certainly have been prevented,

TABLE I. REMOVAL OF THE APPENDAGES FOR DISEASE.

Number.	Date.	Age.	Condition for which Operation was done.	Severity & Duration of Climacteric Symptoms.	Post Operative Menstruation or Vicarious Menstruation.	Effect on the Body-weight.	Effect on Marital Relations.	Condition of Scar.	General Health.
1	5 8 93	29	Appendages very adherent. Tubes swollen, indurated and occluded. Contents—cheesy pus.	Severe. Lasted 3 years.	None.	None.	Coitus always painful before operation. Quite free from pain since.	Good.	"Stronger than she has ever been."
2	22 11 93	36	Double pyosalpinx. Both tubes contained over two ounces of pus. Universal and strong adhesions.	Moderate. Chiefly felt every 4 weeks. Lasted over 2 years.	None.	Slight increase.	(Widow.)	Good.	"Very good."
3	8 2 95	24	Very adherent pyosalpinx on the right side and adherent appendages on the left. Three months pregnant.	After safe delivery of full term child, suffered very severely. Especially every 4 weeks. Still suffers slightly.	None.	None.	None.	Good.	Suffers from severe migraine, and attacks of pain in both groins after hard work. On examination uterus was found to be tender and fixed by adhesions.
4	11 5 94	34	Appendages buried under very dense adhesions. Chronic pyosalpinx of left side and blood cyst of right ovary.	Slight. For nearly 3 years.	None.	Increase.	None.	Thin and stretched in the lower part.	Recovery delayed by abscess breaking into bladder and passage of silk ligature per urethram. Health now very good.
5	25 5 91	22	Right pyosalpinx and left hydrosalpinx.	Severe. Lasted 4 years.	None.	Increase.	None.	Good.	Still occasional pain in the groins after hard work, otherwise good.
6	29 5 94	40	Double hydrosalpinx.	Over before operation.	None.	None.	None.	Good.	"Very good."
7	14 6 94	32	Large double tuberculous pyosalpinx. Tuberculous peritonitis with ascites.	Very slight.	None.	Increase.	None.	Good.	Much improved. "Feels very strong and well."
8	29 6 94	29	Cystoma of both ovaries.	Slight. For over 3 years.	None.	None.	None.	Good.	"Is very well indeed."
9	22 8 94	30	Both ovaries enlarged and in a condition of cystic-ovariitis.	Moderate. Not over yet.	None.	Slight increase.	Pain on coitus.	Good.	No examination made, as patient lives a long way from Birmingham. She writes that she has improved considerably in general health.
10	4 10 94	32	Tubes thickened, occluded and adherent to cystic ovaries.	Moderate. Lasted nearly 4 years.	Regularly (but diminishing) for six months after operation.	None.	None.	In three months developed a hernia of the scar. Operation in Feb., 1895. Condition now very good.	"Excellent."
11	9 10 94	42	Densely adherent right tubo-ovarian abscess and inflamed left appendages. Some ovarian tissue on left side left behind.		Regularly; pain severe; only relieved by a subsequent hysterectomy (vaginal).	None.	No relief to pain on coitus until after second operation.	Hernia of scar gradually developed. Operation two years ago, but is returning.	Has been a "chronic bronchitic" for years, with very severe cough which is very troublesome, and probably accounts for her hernia.
12	16 10 94	36	Inflamed adherent tubes with cystic ovaries. Adhesions very dense and free hemorrhage on separating them.		Regularly. Not so painful or free as before operation till twelve months ago when the pain increased. Relieved by vaginal hysterectomy.	Increase.	None.	In a few months hernia of scar. Operation, 1895. Condition of scar now very good.	History of attack of gonorrhoea 12 months ago. After a great deal of suffering is now getting steadily better.
13	5 12 94	42	Both tubes dilated, occluded and adherent to large cystic ovaries.	Severe — worse every 4 weeks.	None.	Decrease.	No pain, but dislikes having coitus.	Good.	Is almost in a condition of melancholia. Appetite bad, and slowly losing flesh. Was very depressed before operation.
14	10 12 94	43	Appendages adherent. Tubes thickened and dilated.	Moderate. Lasted nearly 2 years.	Every 3 months for the year after operation.	Slight increase.	None.	Good.	"Has not felt so well for years."
15	27 2 95	23	Chronic salpingo-oophoritis with adhesions.	Severe for 12 months, slightly for two years more.	None.	None.	None.	Good.	In Sept. of same year as operation contracted syphilis. Have lost sight of her for last twelve months.

TABLE I. REMOVAL OF THE APPENDAGES FOR DISEASE—(Continued).

Number.	Date.	Age.	Condition for which Operation was done.	Severity & Duration of Climacteric Symptoms.	Post-operative menstruation or Vicarious Menstruation.	Effect on the Body-weight.	Effect on Marital Relations.	Condition of Scar.	General Health.
16	19/4/95	32	Chronic salpingo-oophoritis with adhesions.	Moderate—just over now.	None.	Increase.	Freedom from pain on coitus.	A little thinning in the lower part.	Good.
17	17/7/95	32	Both tubes enlarged, occluded, very adherent to cystic ovaries.	Severe for 18 months.	None.	Increase.	None.	Good.	Fair. Suffers from chronic dyspepsia.
18	28/9/95	37	Cystoma of both ovaries.	Moderate. For 2 or 3 years.	None.	None.	None.	Good.	"Very good"
19	24/2/96	34	Adherent tubes and small cystoma of both ovaries.	Moderate. Exactly every four weeks, just getting over them.	3 months post op 6 months epistaxis. 9 months epistaxis. 12 months after hæmorrhage from bowel.	Slight increase.	None.	Good.	Is very well and strong
20	5/6/96	32	Hard cystic ovaries.	Severe. Especially 4 weeks. Lasted nearly 3 yrs.	None.	None.	None.	Good.	Is not very strong, but on the whole "enjoys good health."
21	29/7/96	34	Pyosalpinx of right side.	Severe for 12 months. Gradually ceasing.	Hæmorrhage from small pile every four weeks.	Slight increase.	None.	Good.	Good.
22	9/1/97	25	Double pyosalpinx and adherent ovaries. Removed by posterior vaginal coeliotomy.	Slightly. Very nearly over.	Every 3 months for 2 years. Nothing for last ten months.	None.	None.		Is in better health than she has been for some years.
23	8/2/97	38	Cystoma of both ovaries.	Severe and not yet over. Worse every four weeks.	None.	Slight increase.	None.	Good.	Is quite well, except for some pain from a movable kidney on the right side.
24	23/2/97	40	Cystoma of both ovaries with ascites.	Moderate for over a year. Not over yet.	None.	None.	None.	Good.	Good.
25	6/4/97	24	Double tuberculous pyosalpinx.	Severe. Every 4 weeks attack of migraine.	None.	Very slight increase.	None.	Good.	Has chronic phthisis. Suffers from cough and shortness of breath.
26	16/8/97	34	Double pyosalpinx. Very strong adhesions.	Moderate. For 18 months. Worse every 4 weeks.	None.	None.	None.	Good.	Very good.
27	13/10/97	33	Cystoma of both ovaries.	Very slight.	None.	Increase.	None.	Good.	Very good.
28	6/11/97	31	Chronic salpingo-oophoritis.	Very severe. Still present.	None.	Slight increase.	(Single.)	Good.	Suffers from the heats and flushes and giddiness. Is quite free from her old pain.
29	7/12/97	21	Double pyosalpinx. About 15 and 5 ounces of pus in right and left tubes respectively.	Moderate.	None.	Increase.	None.	Persistent sinus explored twelve months ago with no result. Still present.	Very good. Sinus troubles her very little.
30	11/1/98	28	Adherent appendages, with thickened and occluded tubes.	Severe, but getting much less so.	None.	Increase.	Slight pain on coitus.	Good.	Fair. Has had scarlet fever since the operation, and has not long been convalescent.
31	18/2/98	29	Cystoma of both ovaries.	Severe exacerbations every 4 weeks.	None.	None.	Pain on coitus diminished, but not gone.	Good.	Is very well except at the monthly emenations.
32	10/3/98	25	Cystoma of left ovary, with twisted pedicle. Small cystoma of right ovary.	Moderate.	None.	Slight increase.	None.	Good.	Occasional attacks of pain in left groin, otherwise is well. On examination can find nothing wrong.
33	23/5/98	21	Double tuberculous pyosalpinx.	Very slight, nearly over.	None.	None.	None.	Good.	Very good.
34	6/7/98	35	Adherent double pyosalpinx. Removed by posterior vaginal coeliotomy.	Moderate. Every 4 weeks only.	Continued for nine months irregularly.	Slight increase.	None.		"Fee's better in every way for her operation."
35	13/7/98	40	Double tuberculous pyosalpinx, universally adherent. Tuberculous peritonitis. Extreme emaciation.						Died two months after the operation from exhaustion. Never began to "pick up" after the operation.

TABLE I. REMOVAL OF THE APPENDAGES FOR DISEASE—(Continued.)

Number.	Date.	Age.	Condition for which Operation was done.	Severity & Duration of Climacteric Symptoms.	Post-operative menstruation or Vicarious Menstruation.	Effect on the Body-weight.	Effect on Marital Relations.	Condition of Scar.	General Health.
36	27/7/98	40	Double pyosalpinx, also three small sub-peritoneal fibroids of the uterus.	Slight. Still present.	Once, 3 months after operation.	Increase.	None.	Good.	"Feels very well."
37	9/8/98	34	Hæmorrhagic cystoma of both ovaries and right hæmatosalpinx.		Regularly. Loses too much.	Decrease.	None.	Good.	Except for losing too much at her periods, is very well.
38	15/8/28	27	Cystoma of both ovaries.	Very severe. Still present.	None.	Decrease.		Pain in the scar from coughing.	Suffers from phthisis, with severe cough and profuse night sweats.

TABLE II. CASES OF MYOMA OF UTERUS.

Number.	Date.	Age.	Size and Position of Myoma.	Chief Symptoms for which Operation was done and Nature of Operation.	Effect on the Myoma.	Severity of the Menopause.	Subsequent History.
1	5/11/93	29	Median tumour of uterus. Softish to the feel.	Hæmorrhage. Removal of appendages.			Died the day after the operation.
2	16/11/93	36	Hard rounded mass size of an orange in posterior wall of uterus.	Pain, especially on defecation. Removal of appendages.	Slight diminution.		In 1896, increase in general size of uterus and increase of pain. Vaginal hysterectomy on December 4th, 1896. Large submucous fibroid and small hard one in posterior wall. Well up to 2 years ago. Cannot trace her since.
3	23/4/94	36	Small fibroid—interstitial expanding uterus upwards.	Severe pain and hæmorrhage. Increase in size during 6 months under observation. Removal of appendages.	Disappeared.	Severe. Lasted 3 years.	Never very strong. Is better than she was, but easily tired.
4	4/4/94	30	Two fibroids—one sub-peritoneal and a largish interstitial one.	Increasing size of tumour and bearing down pain in pelvis. Removal of appendages.	Disappeared.	Moderate for 12 months, then gradually ceased.	Suffers from headache. Is anæmic. Is very poor and has to work hard.
5	27/10/94	45	About the size of an orange. Central in anterior wall.	Continual desire to micturate. Intra-pelvic pain. Increasing hæmorrhage. Removal of appendages.	Disappeared in about 12 months.	Moderate, but over in a few months.	Is very well. Small hernia of scar appeared in 1898. Operation, April 15th, 1898. Condition of scar now is very good.
6	5/11/94	28	Nearly filling up pelvis.	Increasing in size with severe hæmorrhage. Removal of appendages.	Disappeared.	Moderate, only just getting over it.	Has steadily gained in health since the operation.
7	20/12/94	34	About the size of two fists.	Severe hæmorrhage. Also ovarian cyst present. Removal of appendages.	Disappeared.	Moderate—lasted about 18 months.	In excellent health.
8	21/1/95	42	Nearly up to umbilicus. Interstitial.	Hæmorrhage for a year. Removal of appendages.	Disappeared.	Slight and soon over.	Has kept in very good health.
9	26/4/95	35	About the size of an orange, and expanding right side of uterus.	Acute pain and pressure in pelvis for 4 years. Removal of appendages.	For 6 months menstruation continued, then ceased, and tumour has disappeared.	Moderate.	Health very good. Dislikes having coitus.
10	5/6/98	29	Small and low down in the uterus.	Severe hæmorrhage for 9 months. Relieved for a time by curetting. Removal of appendages.	No sign of tumour to be felt. No hæmorrhage since operation.	Severe for 2 years, only lately ceased.	Is very well and able to work hard.
11	31/8/95	35	Large—3 inches above the umbilicus.	Profuse hæmorrhage. Very anæmic and weak. Removal of appendages.	For 9 months no hæmorrhage, and slight diminution.	Severe after the subsequent hysterectomy. Not quite over.	At the end of 9 months renewed hæmorrhage and increase in size of tumour. Abdominal hysterectomy May 10th, 1896. General health fair. Has had a great deal of pain.
12	20/11/95	36	Small hard fibroid in posterior wall of uterus.	Pain and hæmorrhage. Gradually getting worse for 5 years. Removal of appendages.	Disappeared.	Moderate for 3 years.	Has slowly but steadily gained in health.
13	10/7/96	43	Interstitial. Nearly filling pelvis. Three distinct fibroids.	Had had appendages removed in 1883. Pain ever since. Hysterectomy by combined method.		Slight, ever since first operation.	Distinctly better in health. Is troubled by a small sinus in vaginal roof, which I have explored but without result.
14	15/9/96	36	Interstitial myoma up to the umbilicus.	Absolutely blanched with hæmorrhage. Pulse small and quick. Removal of appendages.	Disappeared in less than two years.	Slight.	Is in excellent health.

TABLE II. CASES OF MYOMA OF UTERUS—(Continued).

Number.	Date.	Age.	Size and Position of Myoma.	Chief Symptoms for which Operation was done and Nature of Operation.	Effect on the Myoma.	Severity of the Menopause.	Subsequent History.
15	18/1/97	38	Myoma half way up to the umbilicus, with pyosalpinx of left side.	Hæmorrhage, pain and continual loss of flesh. Vaginal hysterectomy and drainage of pyosalpinx.		Very slight.	Is in splendid health. Better than she has been for years.
16	31/8/97	42	Large myoma, reaching to midway between umbilicus and pubes.	Severe hæmorrhage for 3 years. Blanched, almost pulseless. Vaginal hysterectomy.			Died in a few hours from shock.
17	14/9/97	40	Large median tumour, reaching above the umbilicus.	Hæmorrhage and rapid growth. Abdominal hysterectomy.		Moderate. Not over yet.	Is in very good health.
18	27/10/97	49	Tumour largely occupying the pelvis and rising two inches above the pubes.	Intrapelvic pressure symptoms and very severe hæmorrhage. Patient very anæmic. Removal of appendages.	Disappeared.	Slight and soon over.	"Feels a new woman."
19	20/11/97	37	Tumour about size of a large orange, projecting above pubes.	Severe hæmorrhage for 3 years. Removal of appendages.	Disappeared.	Severe for a few months. Diminishing now.	Is in fairly good health, but still anæmic.
20	11/3/98	40	Large nodular myoma, filling pelvis and rising into the abdomen.	Intrapelvic pressure symptoms and persistent hæmorrhoids. Hysterectomy by combined method.		Slight. Occasional fits of depression.	Is in very good health and feels greatly relieved by the operation.
21	17/3/98	45	Myoma of posterior wall of uterus; filling up Douglas' pouch.	Pressure on rectum. Severe pain on defæcation, with hæmorrhage from rectum. Vaginal hysterectomy.		Moderate every 4 weeks.	Hæmorrhage from bowel every six weeks, getting gradually less. A sinus was left in vaginal roof, from which I removed a ligature. Present health is very good.
22	4/5/98	36	Small myoma and double pyosalpinx.	Profuse hæmorrhage—great pain and emaciation. The vaginal radical operation.		Slight for a few months.	Is in perfect health, looks quite well and plump.
23	4/7/98	45	Myoma, about size of a cocoa-nut: in lower part of uterus.	Pain and continuous growth of tumour. Removal of appendages.	Tumour distinctly smaller.	Severe.	Much better. Gets occasional attacks of pain.
24	14/9/98	45	Myoma, rising above umbilicus.	Severe hæmorrhage for two years. Blanched. Pulse small and very quick. Removal of appendages.	Tumour much smaller.		Twice had severe hæmorrhage at 3 and 4 months after operation. Since then no hæmorrhage and steady gain in health and strength.

and would have been, if the advice of her doctor and myself had been followed.

In conclusion, I can only wish I had had a more interesting paper to bring before you, however interesting these results may be to me, I cannot hope that they will be equally so to you. I know, too, that I have brought forward no new facts. I have not compared my figures with those of other surgeons, my object was to follow each case as well as I could to its condition to-day, and to see if we could learn anything from this investigation. If I have succeeded only in part of my endeavour I shall be glad.

THE RECOGNITION OF ENLARGEMENTS OF THE LEFT AURICLE BY PERCUSSION; AND ON OTHER CLINICAL USES OF DORSAL PERCUSSION, INCLUDING PER- CUSSION OF THE PELVIS. (a)

By WM. EWART, M.D., Cantab., F.R.C.P. Lond.,
Senior Physician to St. George's Hospital, London, and to the
Belgrave Hospital for Children.

In a recent paper read before the Cambridge Medical Society (b), an easy method was described of determining by percussion the left auricle dulness as distinct from the post-cordial dulness. An estimate of the size of the left auricle in mitral stenosis is an essential element, hitherto not available, in the

prognosis of individual cases, and its enlargements and variations most important as guides to the possibilities and the restrictions of treatment. Tracings of great enlargements diagnosed during life and subsequently verified after death were appended to the paper, and also tracings from cases where the auricle had diminished in size under treatment.

The *interscapular dull area* (a) corresponds to the region of the posterior mediastinum, the contents of which are attracting more and more attention in the direction of diagnosis and of treatment. Its percussion is, therefore, of practical importance no less for the physician than for the surgeon, for whom an early recognition of diseases of the œsophagus in particular is a practical requirement. The resulting alteration in the percussion of this area is demonstrated in the tracings.

The *fifth spine dulness* (b) is subject to considerable variations in individual cases, particularly during the life period most liable to glandular affections. M. Fernet has endeavoured to base the diagnosis of early phthisis upon the increased size of the glandular dulness in this region, though he relies at the same time upon the association of other signs at the apex and at the base of the lung. The recognition of the extensive dulness present in some cases of lymphadenoma is easy; but with practice a recognition of smaller glandular enlargements is also within the reach of any clinical observer. For this purpose, however, it is essential that we should be familiar with the small normal dull area, which includes the dulness of the fifth dorsal spine and that of the infratracheal glands in their healthy state.

The *post-splenic dulness* (c) has not been lost sight of in clinical practice, although enlargements of the

(a) Abstract of a paper contributed to the Section of Medicine at the Annual Meeting of the British Medical Association, August, 1899.

(b) "On the Practical Aspects of Dorsal Percussion and in particular of the Percussion of the Spine."—*Lancet*, July 29th, 1899.

(a) Cf. loc. cit.

(b) Cf. loc. cit.

(c) Cf. loc. cit.

spleen usually extend forwards and downwards. It is, therefore, unnecessary to dwell at any length upon this part of dorsal percussion.

A determination of the *post-hepatic dulness* (a) is of clinical interest in all cases, but in some it is of primary importance. Two instances in point are illustrated by tracings. In a case of hydatid of the liver in a boy, considerable enlargement of the left lobe without corresponding enlargement of the right lobe, gave support to the diagnosis of hydatid disease and to its successful treatment by laparotomy. In another case of suspected hepatic abscess, the enlargement was shown by dorsal percussion to affect the right lobe. In cases of simple enlargement of the liver, the fusion of *Piorry's dull nucleus* with the anterior dulness of the liver is an important guide.

The *lower dorsal dull patch* associated with the presence of pericardial effusion, but not produced by cardiac enlargements, has been sufficiently dwelt upon elsewhere.

The *second lumbar spine dulness* has only recently been recognised by the writer as a normal feature in dorsal percussion. Its study will probably be of clinical importance since this dulness appears to be due to the head of the pancreas, to the pylorus and to the surrounding solid structures. A case illustrated by a tracing may be mentioned, in which dulness extended to the right of the normal spinal dulness of the second lumbar spine, and this was the only physical sign yielded by a mass, involving the lower end of the stomach, which was subsequently revealed by laparotomy.

The *upper sacral dulness* is of such slight degree that it may readily be overlooked. So far as the writer has hitherto studied it, this dulness would seem to be one transmitted from the bladder. The resonance of the sacral spine is normally great, but it might be modified by the presence of growths or deposits.

The *renal dulness* and its variations have been constantly under clinical observation, and need not be dwelt upon.

Pelvic percussion might be turned to greater clinical account than heretofore, and in gynaecology its practical usefulness must be obvious. In a case of which tracings were preserved a definite dulness over part of the right os innominatum had led to the diagnosis of a deep-seated abscess. The tumour, which could be felt anteriorly was found at the operation to consist of matted intestine, but the abscess which gave rise to the dulness was beyond the reach of the operation, though its presence was subsequently verified by post-mortem examination.

HOSPITAL ABUSE AND HOSPITAL REFORM. (b)

By F. J. A. WARING, M.D., L.R.C.P.I., Etc.,
Hove.

As far as "hospital abuse" is concerned, I fear that the medical men attached to such institutions are to a large extent to blame, for if they would take a firm stand, and refuse to attend cases of acknowledged unsuitability, the attention of the general and subscribing public would be more fully aroused to the evil; and instead of hearing the everlasting cry that our hospitals are in want of funds, we should find that the subscriptions were ample to meet the needs of the deserving poor. In no town in the

kingdom does abuse exist to a greater extent than in Brighton. For some years past an agitation has been going on at intervals, which first originated with an investigation by the local branch of the Charity Organisation Society; and they issued a pamphlet, showing the astounding extent to which this evil existed. It was, however, in the autumn of 1895 when I first took any step in the matter. I then showed that in 1894 38,113 tickets had been issued from our various charities, and that the population of the joint towns was only 150,000. I drew particular attention to the fact that of the 3,704 births which took place in 1894, the amazing number of 1,240 were attended by the West Street Lying-in Institution, which is a little over one-third of the number; and that this relative proportion was increased when we consider that many of the remaining two-thirds were attended in the Brighton and Steyning unions, and others by a merciful society for helping young women in their first fall. Aroused as I was by this astounding fact, I drew up an address calling the attention of the governing bodies of our charities to this increasing evil, and begging them to take some steps to suppress it. I obtained the signatures of several medical men in leading general practice to this address, but little or no attention was paid to the matter, and the evil was allowed to go on.

In 1897 a further inquiry was set on foot, and we learned that in 1896 43,374 tickets were issued by our local charities, and that the population of Brighton and Hove amounted in that year to 152,000. But, at the same time, there were 14,333 persons belonging to medical aid associations, benefit clubs, and provident dispensaries. Some of these organisations receive hospital tickets, but most of the members are attended by their club medical officers. If to this we add also the asylum, the fever hospital, and Poor-law infirmary, it may be said that one-third of the population of this progressive town pay no medical fees. It is asserted that a certain number of the patients come from the country, but it must be borne in mind that all the large towns in Sussex have hospitals of their own, and nearly all the smaller towns their cottage hospitals.

There is one other matter to which I wish to draw your serious consideration, viz., that the Brighton, Hove, and Preston Provident Dispensary, which endeavours to teach the people to be a little self-reliant, should be lacking in support. Is it not incredible that in the year 1876, with a population in Brighton and Hove of 104,778, the number of members on the books of that institution was more than in the year 1896, with a population of 152,000. The cause, however, is not far to seek: it is beyond doubt due to the ever-increasing hospital abuse in the sister towns.

Children are now educated free, but are we not allowing the parents to become more and more demoralised by mistaken charity. There is, however, some ray of hope to encourage us in our efforts to press on. As I told you that in 1894, the West Street Lying-in Institution attended 1,240 women in their accouchements, being a little over a third of the births in the joint towns. Since then their figures have gone down year by year, until in 1898 they fell to only 892. In the report of that institution, the committee say:—"This probably indicates that the governors are taking additional care to restrict their letters of recommendation to suitable cases." Was I not right in my first contention that there was a gross abuse of that charity? Many of the other hospitals have also shown a marked decrease in their figures for 1898, but there still remains a great deal to be done before the evil is suppressed, which is not only demoralising England

(a) Cf. loc. cit.

(b) Abstract of Address delivered before the Conference Hospital Reform Association, October 10th, 1899.

but spreading its dire influence throughout the world. No men know better than medical men the need of the deserving poor, and no men minister more tenderly or more mercifully to them in their hours of sickness; but they should not be expected to extend that gratuitous aid to those who can well afford private medical attendance.

My contention is that for a population like Brighton and Hove of 156,761, for 1898, we have far too many hospitals, and that much could be saved by some, at least, of these institutions being housed under one roof. For 1898, the West Street Lying-in Institution, which dealt with only 83 in-patients and 920 out-patients, spent £541 15s. 4d. for wages and salaries, whereas the Sussex County Hospital, with 1,699 in-patients and 6,986 out-patients, expended £2,844 5s. 3d. Of the Throat and Ear Hospital, which has only just moved into new quarters, I can give no accurate account for 1898, but I contend that both these institutions might be under the roof of the Sussex County Hospital, occupying not more than two extra wards, and that both in clerical staff, nursing, outlay of building, &c., a vast sum might be saved. The Eye Hospital allows eight tickets for one guinea, and for three guineas sixteen out-patients and one in-patient letter, and so on in proportion. The Throat and Ear Hospital requires each patient to present a "Subscribers' free letter," or to pay at the first attendance the sum of five shillings, presenting at the same time a (pink) letter of recommendation for paying patients. (N.B.)—I want you, my friends, to think over this "Nota Bene." Letters for "Paying Patients" are supplied to subscribers, who can give an unlimited number away. There is no foot-note begging the subscriber to be careful to see that the "Pink Letter" is only given to the necessitous poor. A patient suffering with the troublesome defect of impacted wax in the ear, and under the impression that it is of a worse nature, may pay his five shillings and go to the hospital and have it syringed out, whereas if he had gone in the first instance to some young and struggling practitioner, he would quite as skillfully have performed that simple operation for half-a-crown. The Royal Alexandra Hospital for Sick Children takes sums varying in amount from parents who can afford to pay. Then, again, look at the privilege given to annual subscribers to the Brighton, Hove, and Preston Free Dispensary, who are allowed the outrageously large amount of twelve letters of recommendation for one guinea. No wonder that the numbers attended are enormous, and that the letters are distributed without discretion. Patients have to pay the sum of sixpence for each letter. These letters are supposed to last only one month. Now, some patients get as many as six, or even eight letters in a year, and there are cases where the same patient has been known to get as many as twelve letters. Why should not these patients have been encouraged to join a provident dispensary? We have in Brighton an exceptionally well-to-do working class who should be induced to pay into provident dispensaries upon a graduated scale according to weekly earnings. Surely, if they can pay the money when sick they can pay it when in health, and have, in addition, the feeling that they are not being pauperised. For those who are really too poor to pay anything there is our Poor-law system to meet their case. I object to free dispensaries altogether as having an evil tendency, and I object still further to the system of hospitals and dispensaries taking any payment as entering into unjust competition with the medical practitioner. I contend that if any money is taken, it should go towards a fund for paying the, at present, honorary staff. I will give in a few words the

method I would adopt to help remedy this evil, for evil it is. I would establish in every town, at convenient distances, "bureaus," to which the necessitous poor could apply for tickets, and if there should be any doubt about the case let the inquiry officer make an immediate investigation. These "bureaus" would be a blessing to the poor, who would at once know where to apply in case of sickness, instead of rushing, as I have known them to do, in all directions to find some one with a ticket to spare. I know that this is met by the objection that the subscribers do not like to give up their privilege of distribution. I would reply that by all means let the subscribers have the power of recommending to the officer in charge of the "bureau" any case they choose, to the extent of their subscription. I know that there are many subscribers who wish to be relieved of the nuisance of being applied to for tickets, and who frequently hand them over to the clergy of their parish, or to the parish visitors, who do not always act with discretion. Whether this question is settled now, or deferred, as many important matters are, to some future day, depend upon it, it is an evil that must eventually be checked.

MODERN AND CELTIC MEDICINE.

Abstract of an Inaugural Address delivered at the Mater Misericordiae Hospital, Dublin.

By THOMAS MORE MADDEN, M.D., F.R.C.S.Ed.,
M.A.O., *Honoris Causa*, Royal University,
Obstetric Physician and Gynaecologist to the Hospital, &c.

WITHIN the period covered by this address the vital importance of thoroughly aseptic conditions in all that appertains to the care and treatment of the sick has become universally recognised. With this view therefore our operating theatres have been reconstructed, ventilation and drainage improved, and a most efficient and well-trained nursing staff provided for our public and private wards as well as for the necessities of general practice throughout every part of the country wherein the services of the Mater nurses are in constant requisition.

Whilst such consideration has been given to the primary purpose of these institutions, those entrusted with their administration have in nowise been oblivious of their secondary and almost equally important function, viz.: that of serving as a centre of clinical medical education and scientific teaching, and the influence of such clinical teaching has been dispersed abroad and at home, *orbi et urbi*.

Thus in every clime, or place, or circumstance, when medical men have faced death to save the lives of others, from the fever-stricken districts of our own land, to the malarial swamps of Africa, the plague-infested cities of the Far East, or the battle fields of the Soudan or of the Indian frontier, there have they been found discharging their mission of mercy to humanity.

Turning for a moment from the work of the hospital to that of the healing art, of which it is the clinical theatre, we find here, as elsewhere, the most distinct imprint of recent progress in every department of practical medicine, surgery, and gynaecology, as well as in ophthalmology, dermatology, and the other special branches of modern medico-surgical science. The rapidity of this advance has been such that the highest professional accomplishments attainable twenty years ago, have already become almost as obsolete for a student as the knowledge of Hippocrates in physic, or the skill of Ambrose Paré in surgery, might prove, could either be now tested by a modern Conjoint, or Royal University Medical Examination.

So many and complex are the factors in that revolution in medicine, that it would be useless to attempt any survey, however brief, over a field of such extent.

In the domain of surgery the evidence of rapid advance since my former address is yet more apparent than in that of medicine, as may be exemplified by a moment's reference to the upgrowth and development of antiseptic surgical practice within that period. The fruits of this are, perhaps, most conspicuous in the successful operations now resorted to in countless cases—such, for instance, as tuberculous peritonitis, renal, intestinal, gastric, and other diseases and lesions within the peritoneal cavity from any effective interposition with which our predecessors were almost necessarily debarred.

These procedures, with many others of equal importance that need not be here enumerated, which in my earlier days were either altogether undreamt of, or which, if occasionally attempted, were then associated with such fatality as to preclude their general performance, are now daily accomplished with smaller risk than might have attended the opening of a whitlow in pre-antiseptic days.

I cannot altogether refrain from alluding to the branch of medicine with which I am most intimately concerned, but however tempted I may be to dilate on the progress of modern gynaecology, I shall confine, within the narrowest possible limits, my reference to a subject that, however interesting to myself, would probably prove intolerably wearisome to the majority of my present audience. It will, therefore, be enough to say here that this youngest of the tripart divisions of the healing art has exhibited a progressive development fully equal to that of either of its medico-chirurgical parent sciences, and that this specialism, the very name of which was unknown in my youth, has within the past few years advanced by leaps and bounds to its present prominence in the foreground of medical progress.

The diseases and abnormalities of what was formerly the *terra incognita Australis* of pathology, viz., the region of the uterus and its appendages, have now become as accurately differentiated and as successfully treated as those of any of the external structures of the body. Thus, for instance, fibromyomata and carcinoma of the uterus, the various displacements of that organ, the affections of the ovarian and tubal adnexa, with numberless other gynaecological disorders, the victims of which were formerly in many instances, abandoned to lives of hopeless misery, have now been brought within the reach of accurate diagnosis, and generally successful treatment.

Gentlemen, on entering the medical profession, you must assume many responsibilities as well as gain some privileges. On you, therefore, it will devolve to support the reputation of your calling by a conscientious zeal in the honourable discharge of your great mission to the poor and suffering. Moreover, it will be your duty to add your mite of experience and of knowledge to that cairn of medical science which has been brought up to its present height by the aggregation of the individually minute contributions of your predecessors—and so maintaining the great traditions of Irish medicine, to hand it down to your successors improved and perfected by your labours.

CELTIC MEDICINE, ITS HISTORY AND LESSONS.

Lastly, I may for a moment refer to the too generally forgotten fact that Irish medical men can lay claim not only to the traditions they inherit from their more immediate predecessors, but also to a history deserving of larger consideration than is commonly given to it. For, as I have else-

where shown, the practitioners of the healing art in this country are, in truth, the legitimate heirs of the oldest professional culture of which there are in existence the records in the living language of any European nation. Let me, therefore, remind you that in distant ages when the lamp of medical knowledge was unkindled in most other countries, its light shone with comparative brilliancy in this remote *Ultima Thule*. Thus, there are still extant and accessible in the libraries of the Royal Irish Academy and Trinity College in this city as well as in other similar collections elsewhere, a vast body of ancient Gaelic MSS. documents in which the distinguished history and character of early Irish medicine are well illustrated.

From these sources we find that from the oldest period of authentic history the classic literature of Greek and Roman medicine as well as a still more ancient native leechcraft, was cultivated in our own country. Nay more, we have clear evidence that the marvels of modern hypnotism and the employment of anæsthetics on which we plume ourselves as the most beneficent discovery of the present age, were, although in cruder forms, here anticipated by our remote predecessors.

Among the numerous collegiate centres of professional as well as of ecclesiastical learning with which this *Insula Sanctorum et Doctorum* was studded over between the sixth and sixteenth centuries, one, at least, is of special interest to us as of a distinctly medical origin and character, viz: *Tuam Breccin*, near the present town of Belturbet, which was established by a medical practitioner of no little eminence, viz., Saint Brecin, whose surgical skill is celebrated in our oldest annals. From these institutions were sent forth men such as Alcuin, the founder of the University of Pisa, Johannes Scotus Erigena, who in the eighth century was professor of philosophy in Paris, and countless others to diffuse the lights of learning and science as well as of faith to the ends of the earth.

To the destruction of those Celtic monastic universities, may be dated the origin of the disabilities in the matter of higher education that for three centuries have pressed, and still press heavily on the majority of the Irish people, and on none more forcibly than on those of them belonging, as so many here do, to the medical profession.

The latter, during all these generations, have been thus unfairly handicapped in the race of existence by the impossibility of securing, in accordance with their conscientious convictions, that full measure of academic training within the halls of a University which is so conducive to success in the higher walks of professional life or public employment, and which is accessible to their compeers of every other persuasion.

We may, however, rest well assured that in this, as in all other matters, justice, although long delayed, must like that truth on which it is founded, eventually prevail. And therefore can we confidently anticipate that this last vestige of the dark shadows cast over our land by the successful intolerance of a by-gone age may for ever be swept away in the near day-dawn of the Twentieth century which we trust will usher in the final and equitable adjustment of the Irish University Question. Whether in our day this long-cherished hope be realised or not, will, we are equally confident, in no wise affect your kindly relations and zealous co-operation in the mission of medicine with your brother practitioners of all other schools and denominations. Nor need we attempt to stimulate your esteem and respect for men among whose professional ancestors were included names such as those of Cusack, Carmichael, Graves, or Stokes, which at home and abroad are as imperishably engraved on the annals of our science—as those

of their Catholic compeers—Corrigan, O'Reilly, Lyons, or Hayden. Or who, like the Anglican founder of Sir Patrick Dun's Hospital, or Bartholomew Moss, to whom Ireland owes her great school of midwifery, the Rotunda; have left in our city enduring monuments of a medical benevolence as far above all sectarian considerations as that of the founders of the four Catholic hospitals which are so largely supported by Irish charity in Dublin.

In conclusion, I would only venture to express my trust that in the fulness of years, you, gentlemen, may one and all leave behind you such imprints on the sands of time as those I have just named did. Thus will you not only honour yourselves and your calling, but also perchance reflect some of your well-won credit on your clinical *alma mater*, and on those who were once your teachers in the Mater Misericordiae Hospital.

Clinical Records.

ST. MARY'S HOSPITAL.

A Case of Paresis of both External Recti Muscles of the Eyes, with Retinal Hemorrhages and Staggering Gait Simulating Intracranial Disease. (a)

Under the Care of HENRY JULER, F.R.C.S.,
President of the Harveian Society.

WILLIAM B—, æt. 35, fishmonger, on October 4th, 1899, was suddenly attacked with diplopia and vertigo. There was no history of syphilis. Seven years ago he was laid up from a blow on the head caused by a fall of fourteen feet and followed by delirium. Has been a hard drinker, chiefly of beer. Has been treated for some time for "kidney disease."

On admission to St. Mary's Hospital on October 13th, his right vision was $\frac{1}{2}$ and J 1, left vision $\frac{1}{2}$ and J 20.

He had paresis of both externi and consequent convergent strabismus. On fixing with right eye the left eye turned inwards from 10 to 15 degrees. The movements of both eyes are good in all directions except outwards; each eye on attempting abduction becomes nystagmic and cannot be moved beyond the middle line. He is unable to walk with both eyes open on account of diplopia. With one eye closed he can walk better but still unsteadily. Both pupils active to light and accommodation.

Both optic discs hyperæmic and slightly blurred in outline. One or two torch-like hemorrhages in the right retina.

Knee-jerk present and equal. Grasp good on both sides. Urine sp. gr. 1018, containing more than a trace of albumen.

On October 12th he had a kind of fit. His sister, who saw it, says that it lasted about half an hour. It began with convulsive movements of the feet and legs and then passed over the whole body. He was delirious and talked incessantly, but he does not remember the attack.

Dr. Caley saw the case and admitted him to the wards, and found the pulse of slightly increased tension; the heart hypertrophied on the left side; the urine still albuminous, and presenting signs of chronic nephritis in the shape of slight granular casts. After admission, there was rapid improvement of the ocular symptoms, so much, indeed, that to-day, six days later—the ocular palsy has almost disappeared, there being only slight paresis of the right ext. rectus appreciable. The diplopia also has nearly disappeared, although he still prefers to shade one eye.

There has been no return of the ataxic symptoms which were present at first, nor are there at the present time any positive indications of organic intracranial disease or of a nuclear lesion.

This fact taken in conjunction with the rapid subsidence of the ocular paralysis, strongly suggest a toxic origin for the latter. The toxæmia in this case might either be alcoholic or uræmic. It is very unusual to find ocular palsy of alcoholic origin without evidence of

alcoholic multiple neuritis. On the other hand, had it been due to uræmia we should have expected unequivocal uræmic manifestations, but inasmuch as he was at the time suffering from definite nephritis we clearly cannot exclude uræmia.

The case is one of great clinical interest, and it may prove itself to be due to the alcohol *plus* nephritis.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, OCTOBER 27TH, 1899.

SIR RICHARD DOUGLAS POWELL, Bt., President, in the chair

CLINICAL EVENING.

CEREBELLAR SYMPTOMS RELIEVED BY TREPHINING.

DR. L. GUTHRIE and Mr. STANSFIELD COLLIER showed a case of tumour of the middle lobe of the cerebellum treated by trephining and drainage. The patient was a boy, æt. 9, who at present, eighteen months after the operation, is in perfect health except for blindness due to double optic neuritis. Dr. Guthrie observed that the operation ought to have been done a month earlier for in such a case he believed sight might have been preserved.

THE PRESIDENT remarked that if it were really a case of glioma, it was surprising that there were no further symptoms.

CASE OF ACTINOMYCOSIS IN PROCESS OF CURE.

MR. G. R. TURNER showed a case of actinomycosis on the mend. The patient first came to the hospital with what looked like an abscess of the neck. This had previously been incised, leaving a fistula discharging a thin serous purulent fluid which, on examination, proved to contain the ray fungus. Iodide of potassium was given in doses of 15 grains, rapidly increased to 45 and upwards. The abscess cavity had also been scraped. The result had been most satisfactory.

MR. SLATER, who had examined the secretion, remarked that the fungus was not readily found in man, and raised the question whether there was any actual proof of the disease being caused, as supposed, by the fungus. He suggested that it might be caused by more than one organism.

MR. BARKER remarked that as the disease usually occurred in some sort of connection with the alimentary canal, it was reasonable to suppose that this was the channel by which the fungus entered. He admitted, however, that the disease sometimes occurred in other situations, and he mentioned a case in which the growths were located in the abdominal wall in a patient, who presumably had never come into contact with hay, he being dispenser to a country doctor.

CASE OF OSTEITIS DEFORMANS.

MR. G. R. TURNER also showed a man, æt. 74, admitted to St. George's, complaining of swelling of the upper jaw, principally affecting the alveolar process, and most marked on the right side, of about eight weeks' duration. There was also general enlargement of the head, evidenced by inability to put on his hat. The tibiae and ribs were also affected, and the breathing was principally daphragmatic. No venereal history. The nervous system appeared normal, but he walked with a shuffling gait. He had improved under iodide of potassium.

DR. EWART asked if accurate measurements had been taken. He himself had often failed with the iodide.

THE PRESIDENT asked whether there had been any loss of weight?

MR. TURNER replied in the affirmative and admitted the possibility of malignant disease.

KRASKE'S OPERATION.

MR. J. JACKSON CLARKE showed a man, æt. 56, on whom he had performed Kraske's operation for the removal of a cancerous growth of the rectum. He remarked that

(a) Read before the Harveian Society of London, Oct. 19th, 1899.

with patients not too old, and whose general health was good, he much preferred this operation to colotomy.

OLD DISLOCATION OF THE HIP WITH FRACTURE OF ACETABULUM.

Mr. WATSON CHEYNE showed a man, *et. 60* who six weeks before had sustained a severe injury, for which he was treated at a hospital. When first seen by him he was quite unable to stand, and when assisted into the erect posture on one leg, the right thigh was flexed and the foot everted. Flexion and adduction, with extension, were possible, but abduction was very limited. Nine weeks after the injury he cut down on the joint and found a dorsal dislocation, *plus* a fracture of the acetabulum, the cavity of which was filled with soft material. He reduced the dislocation by manipulations, and after two months he was able to get about, the legs being then of the same length.

SUPPOSED CYSTIC DISEASE OF THE KIDNEYS.

Dr. SIDNEY PHILLIPS showed a patient who, after an accident, had hæmaturia, and was supposed to have ruptured his kidney, but he soon recovered, and remained well until October 2nd when he came complaining of pain in the shoulders and in left side of the abdomen. The urine was dark. On admission into St. Mary's, there was some effusion into the joints, and on examination he discovered two previously unnoticed tumours in the abdomen, the left being the larger. The tumours were large, movable, and well defined above. He presumed that the tumours were renal. The patient passed 64 ounces of urine daily, *sp. g.* 1011, containing 1.20 of albumen. His general health was good, and there were no symptoms referable to the tumours, which had a nodular surface, and no fluctuation. Dr. Phillips suggested that the patient had congenitally cystic kidneys, which had undergone sudden development.

Dr. COODE ADAMS referred to the case of a boy, *et. 11*, who had been under his observation for two years. He had been unable to discover anything wrong. The patient was found dead in bed one morning, and post-mortem cystic disease of both kidneys found. In reply to the President he said that the heart was normal.

Dr. PHILLIPS, in reply to the President, said the excretion of urea was normal. In view of the history he did not think malignant disease was likely, especially as there were no symptoms.

UPWARD DILATATION OF THE STOMACH.

Dr. EWART showed two patients illustrating upward dilatation of the stomach and its bearing upon the heart and respiration. He showed diagrams illustrating the different directions which the dilatation might take. In one form respiration was principally interfered with, while in the other the patient suffered from severe anginal attacks. He advocated mechanical treatment from above, supplemented by mechanical treatment from below—*e.g.*, reinforcing the abdominal muscles by an abdominal belt.

RAYNAUD'S DISEASE WITH CHRONIC RHEUMATISM.

Dr. HERRINGHAM showed a young man, *et. 30*, suffering from scleroderma with local syncope. Since Christmas he had complained of pains in the hands and arms, subsequently extending to the shoulders, followed in the spring by attacks of "deadness" of the hands. During the attacks the hands became white and cold, though the radial pulse was normal. Since then he had been kept in bed and the attacks had subsided. He pointed out that local syncope was one of the forms described by Raynaud, but in this case the condition of the skin was the primary and principal disease, and it involved other parts, such as the back. The flexor muscles of the wrist were contracted, and on movement the tendons grated in their sheaths. The feet were also involved. The patient had never had syphilis and was the father of two healthy children.

RECURRENT CARCINOMA OF THE BREAST TREATED WITH THYROID EXTRACT AND OOPHORECTOMY.

Mr. R. EVE showed a woman, *et. 44*, who in 1892 first noticed a lump in the right breast. She came to him in 1895 with ulcerated schirrus, adherent below. Glands not obviously enlarged. He removed the breast freely

and cleaned out the axilla. She continued well till the summer of 1898, when she presented herself with nodules in the skin above the scar and very definite infiltration at the centre of the scar. The superclavicular glands were enlarged. He removed the ovaries and soon after put her on thyroid extract, 15 to 20 grains daily. Within three months the central infiltration had disappeared along with the glandular enlargement, so that in March last she was apparently quite free from disease. At present, however, nodules had formed around the scar and the glands were enlarged in the posterior triangle. He concluded that, although the disease had been greatly delayed, it had evidently only been latent.

Mr. STANLEY BOYD observed that it was very difficult for any individual surgeon to form a clear idea of the value of oophorectomy in these cases, for while it had a marked effect in some cases, it had no influence whatever in others. Moreover, the good results were obtained in some of the most unlikely cases. He referred to a case which he had seen with Mr. Watson Cheyne, of a large recurrent ulcer over the chest in a woman of 48, who was still menstruating regularly. Oophorectomy was performed in June, and by September the surgeon had written to say that a cure had taken place.

Mr. WATSON CHEYNE referred to two other cases of his own during the present year. The first case had improved for six months, and had then gone to the bad. The second case was that of a lady whose breast had been removed six years ago. She came five years afterwards with very extensive recurrence. This he removed, but in six months she returned with enlarged glands deep down in the neck. Oophorectomy was done in July, and when seen the other day the whole of the disease had disappeared. He also referred to a third case which came under his notice in May. The patient had had several operations for cancer of the breast, and presented herself with a large cancerous mass impossible of removal. As she had a large fibroid, and was losing large quantities of blood, he felt justified in removing the ovaries, at the same time removing as much as possible of the cancer. That was six months ago, and since that time the fibroid has disappeared, and the cancer had not yet recurred. He agreed that it was impossible to say beforehand which cases would benefit by the operation, and which not.

Mr. EVE, in reply, mentioned the case of a lady, *et. 43*, with a large schirrus, involving the skin and the axillary glands. He operated, and then gave thyroid extract, but the disease recurred within two months, and rapidly spread over the chest. As a last resource he performed oophorectomy, and continued the thyroid treatment, but without the slightest effect.

BIGG'S SPLINT FOR FRACTURED CLAVICLE.

Mr. BIGG showed a man who had sustained a severe comminuted fracture of the outer third of the clavicle, treated by his specially devised splint, and he insisted on the advantages which this splint presented in securing perfect immobility of the fractured surfaces, with consequent small formation of callus.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, OCTOBER 12TH, 1899.

The President, Dr. MACNAUGHTON-JONES, in the chair.

(Continued from page 425.)

Mr. J. FURNEAUX JORDAN (Birmingham) read a paper

ON THE AFTER RESULTS OF OPERATION FOR THE REMOVAL OF THE UTERUS AND APPENDAGES, which will be found on page 443 under the heading of "Original Communications."

In the discussion that followed the reading of this interesting paper—

Dr. ARTHUR GILES expressed his appreciation of Mr. Jordan's excellent and useful paper. The after-result constituted one of the chief warrants for certain operations, and there was too little known about them. Hence such a contribution as Mr. Jordan's was of t-

greatest value. With regard to the operation for the removal of diseased appendages, his experience was that such patients did not suffer markedly from the effects of the artificial menopause. This was no doubt due to the fact that for some time the diseased organs had not been carrying on their functions properly, and consequently their removal had less effect than was the case with relatively healthy organs removed for myoma, for instance. This was an additional argument in favour of hysterectomy rather than oophorectomy in the treatment of myoma. He observed that Mr. Jordan had had comparatively few cases of oophorectomy among his later operations for myoma.

Dr. HEYWOOD SMITH said that it was very interesting to note in the second table the disappearance of the tumour in so many cases, especially among the younger women. The removal of the ovaries after the time of the menopause was, however, also followed by diminution in the size of the tumour, as he had found in many cases; but this was rather difficult to explain scientifically. He thought that even now they should consider in certain cases the advisability of removing the ovaries for myoma, as against hysterectomy; on the other side the fact was to be remembered that after oophorectomy the uterus might go on increasing in size. The question was a large one and might profitably occupy a whole evening's discussion. He noticed that among the cases of diseased appendages, four were put down as tuberculous; probably many of these cases were overlooked in the ordinary course of things. Sixteen cases were gonorrhœal, and it was important to note that infection might be conveyed by men whose gonorrhœa was thought to have been cured years before. He would ask Mr. Jordan whether he had tried ovarian extract in cases where women had had symptoms after removal of the ovaries, and if so, with what result?

Dr. HERBERT SNOW endorsed the remarks of a previous speaker on the interest and great importance of this paper. He noticed in the second table that among 38 cases, only one was mentioned as single; were all the others married? With regard to the question of removal of ovaries or uterus for myoma, he believed that most women would prefer to have the tumour removed once for all, rather than even to watch the process of its getting smaller. The disappearance of tumours should always be received with great reservation, in the absence of a post-mortem examination; diminution in size was not uncommon, but disappearance was rare.

Mr. BOWREMAN JESSERT, referring to the treatment of pyosalpinx by vaginal drainage, said that it seemed to him a very good plan. In cases where pyosalpinx had been dealt with by laparotomy he had seen the abdomen flooded with pus. The operator would be spared much anxiety and the patient much danger if these cases were treated by vaginal drainage. For myoma he preferred to remove the uterus and leave the appendages, rather than remove the latter and leave the tumour; the risk of hysterectomy was not now much greater than that of oophorectomy. He had treated a certain number of patients with ovarian extract, after removal of the appendages and in some cases with marked benefit. He would like to hear Mr. Jordan's experience on this matter.

Dr. R. H. HODGSON asked Mr. Jordan whether he had any experience of tubes becoming affected after curetting; and whether it might not occur in such a case that the infection travelled by direct continuity between the uterus and tubes?

The PRESIDENT thanked Mr. Furneaux Jordan on behalf of the Society for his valuable and interesting paper. Some of the questions which it raised had been discussed at the recent Amsterdam Congress; thus Doyen and Schauta had quite discarded oophorectomy for myoma. But it was strange how the experience and teachings of Battley, Tait, and many of the American school had been overlooked. For his own part, he did not at all agree with the idea that myoma must always be treated by hysterectomy, for he thought there was a class of case in which oophorectomy was much better. It was a growing opinion, both in Great Britain and in America, that the uterus was removed in a great number of cases in which it

would be much better left alone. For instance in some Continental towns the uterus was removed in every case of adnexal disease. The radical treatment was, however, necessary in some cases; and he believed that in pyosalpinx with adhesions the classical treatment was removal of uterus and appendages and drainage through the vagina. The high mortality of operations for pyosalpinx was easily understood; for pus sacs might rupture and give rise to septicæmia, even when the most elaborate and careful aseptic preparations had been adopted; this was the reason, it seemed to him, why the best treatment was panhysterectomy and drainage. As regards removal of diseased appendages by colpotomy, he did not think the vaginal route was the easiest, but he believed that this was the operation of the future for conservative operations on the appendages, and in some cases, for their removal. As to drainage, glass drainage tubes should be relegated to museums; soft tubes were better, and iodoform gauze better still. The iodoform should, however, be sterilised before use, otherwise it might be most dangerous. He believed that in most cases sexual feelings were not affected by operations for the removal of the appendages. A patient on whom he operated ten years ago for disease of eighteen years' standing, had got married within the last year; and she had not lost sexual feeling and desire. He believed with Lawson Tait that in most cases troubles arising after the removal of the appendages were the result of incomplete operations.

Mr. FURNEAUX JORDAN, in reply, thanked the Fellows of the Society for their appreciative hearing of his paper. The main object of his inquiry was to discover whether patients suffered most after removal of the uterus or after removal of the appendages. It was a question which could be settled by careful inquiries by all surgeons as to the after-results of their operations. The conclusion to which he had come was that it was not simply a question as to which organs were removed, but also as to the age of the patient; the nearer to the age of the natural menopause, the less was the disturbance. He had found that post-operative troubles were less after oophorectomy for myoma than after the removal of diseased appendages, but it was to be noted that patients of the latter class were generally older. He had had no experience of treatment by ovarian extract, but thought it might be worth a trial. As regards the treatment of pyosalpinx, he thought that the results were much better from vaginal incision and drainage, than from removal of the appendages through the vagina, not only on account of the diminished risk of pus in the abdominal cavity, but also because of the frequent bowel adhesions in these cases. Moreover, he saw no advantage in removal of the uterus in these cases; drainage appeared to him to be sufficient. As he had stated in the paper, he thought that in cases of myoma with much hæmorrhage and blanching it was better to remove the appendages than to attempt hysterectomy; because, after all, the latter procedure involved much more shock; and if the removal of the appendages involved a second operation later on, the latter was done under conditions of much greater safety for the patient; and was rendered all the easier by the previous oophorectomy.

HARVEIAN SOCIETY OF LONDON. CLINICAL EVENING.

MEETING HELD THURSDAY, OCTOBER 19TH, 1896.

The President, H. E. JULER, F.R.C.S., in the Chair.

THE PRESIDENT exhibited

A CASE OF MICROPHthalmos IN A CHILD, AT SEVEN.
The right eye was very small, only half the size of the left, and sunken in the orbit. The cornea was clear, but only measured 6 m.m. in diameter. The iris slate coloured, no reticulum visible, pupil very ill-defined. The condition was probably congenital. The eye was quite blind, there being no perception of light. Left eye was normal and vision good. It was proposed to remove this eye on account of deformity.

In reply to Dr. Felce, Mr. JULER agreed that evisceration would be better than enucleation, and in answer to Dr. Sutherland, said there were no other congenital defects in this case.

The PRESIDENT also showed an interesting case of Paresis of both External Recti, notes whereof will be found under "Clinical Records."

Dr. JAFFE thought the symptoms were probably of uramic origin.

Dr. CAUTLEY asked if there was further evidence of chronic interstitial nephritis in the presence of cardiovascular changes. He pointed out that albuminuria might occur in heavy beer drinkers, apart from renal changes demonstrable either macroscopically or microscopically. No doubt the explanation put forward was the correct diagnosis of the case.

The case was also discussed by Dr. Harris, Dr. Felce, and Dr. Smart, and the President replied.

Mr. RAYMOND JOHNSON brought forward a case in which he had performed so-called arthrodesis of the knee-joint. The boy, who was *et.* 16, had suffered from infantile paralysis in infancy, and was left with almost complete paralysis of the muscles moving the right knee, and partial paralysis of the muscles of the leg. The knee-joint was opened, and after the removal of a thin slice from the femur and tibia the two bones were pegged together. Bony ankylosis followed, and the boy was now able to walk with the use of any apparatus beyond a thick-soled boot. In a considerable number of cases of infantile paralysis [this operation had been performed with advantage to the knee and ankle.

LAPAROTOMY FOR PERSISTENT VOMITING.

Dr. EWART and Mr. JAFFREY related a case in which laparotomy was resorted to for the relief of persistent vomiting with exhaustion in a woman, *et.* 49, in whom a pulsating swelling, supposed to be connected with the stomach, could be felt in the left epigastrium. Mr. Jaffrey found the stomach healthy though much dilated, the pyloric end was flattened and tightly stretched across the convexity of a fusiform abdominal aneurysm, so that no fluid could pass through to the duodenum. An incision between four and five inches long was made above the umbilicus, the stomach presented in the wound. It was quite healthy, and was lying on the left side of the aneurysm. The flattening was partly due to the weight of the stomach and its contents, and of the colon and omentum. By bringing the stomach to the right of the aneurysm it was seen that the flattening was at once relieved, and as the stomach did not appear to be inclined to fall back into its former position it was thought unnecessary to fix it in any way. Silkworm gut sutures and dry cyanide gauze were used. With the exception of some vomiting, due she said, to the smell of brandy, she recovered quickly, and is now able to take solid food. She complains still of some burning sensation in the epigastrium, and has general hyperæsthesia of the abdomen. The pulsating mass is now less easily felt, no doubt due to the fundus of the stomach being between the aneurysm and the abdominal wall. The stomach in this case had been occluded by its own weight, an unusual and striking instance of the mechanism described in succession by Rokitsansky, Glenard, and others, and recently studied by P. A. Albrecht (*Virchow's Archives*, Bd. 156, Heft 2, 1899), where obstruction is produced at the jejuno-duodenal junction by the dragging weight of the small intestine. His other female patient, *et.* 59, who died from pernicious anæmia, with exhaustion and persistent vomiting, exhibited the condition described by these observers, which Albrecht believes to be a frequent cause of acute gastric dilatation, and of death after severe operations, which may lead to gastric atony, partly as a result of the prolonged administration of anæsthetics. The empty and contracted small intestine had dropped entirely into the pelvis, stretching the mesentery and superior mesenteric artery tightly across the third portion of the duodenum, which above the occlusion was inflated and contained feculent fluid. The stomach in this instance was not dilated, but empty and contracted. The possibility of treating this

fatal condition without laparotomy, and by such simple methods as posture and manipulation, is the practical and important object of this communication. In all cases of persistent vomiting not traceable to some obvious cause, in marasmic and exhausted subjects the effect of the right lateral posture, of raising the foot of the bed, and of skilled manipulation of the abdomen by the medical attendant should be tried. This might, in some cases, prove successful, and obviate the necessity for surgical interference.

Dr. JAFFE asked whether the stomach had been washed out before resorting to operation for the relief of the vomiting?

Dr. EWART replied in the negative, and said the original diagnosis was carcinoma of the stomach.

Dr. WHITFIELD showed a case of Linear Lichen Planus in a married woman, *et.* 34, previously in good health. The eruption had commenced about 1½ years before on the skin over the left tibia, immediately above the ankle. When shown, there was a band of the eruption, about 1½ inches wide, extending from the front of the ankle to the inner condyle of the left femur. At the edges of the band typical lichen planus papules, about the size of a split hempseed, could be seen, but in the centre they had run together to form a solid raised ridge.

Dr. J. W. HARRIS exhibited a man, *et.* 31, who was the subject of extreme myopathy of the fascio-scapulo-humeral type.

OBSCURE CASE OF EXTENSOR PARALYSIS OF FOREARM.

Dr. LEONARD GUTHRIE showed a man, *et.* 38, suffering from complete paralysis of the wrist extensors and of the elbow flexors on both sides, with the exception of the long supinators. The affected muscles were much atrophied, and did not react to faradism. The intrinsic muscles of the hands, flexors of the fingers and wrists, and the shoulder muscles were unaffected. Sensation was normal, and there was no pain or tenderness of muscles or nerve tremors. The wrist drop had occurred two years previously, and both wrists were almost simultaneously affected. Twelve months later the elbow flexors of the left side had been involved, and eighteen months later those on the right side. The case was regarded as one of lead palsy. The patient was a shoemaker. He had never worked with lead, nor suffered from colic, and there was no definite blue line on the gums. But he had been in the habit of taking four or five pints of 4d. ale daily, and this beverage was said by some to be productive of lead poisoning, especially in gouty subjects like the patient.

CARCINOMA OF TESTICLE.

Mr. MOWER WHITE showed the left testicle, which he had about two years ago removed from a patient, *et.* 37, on the supposition that the globus minor of the epididymis contained a deposit of "tubercle." After removal dissection showed that the nodule, which measured from ¼ in. to ⅓ in. in diameter, was situated in the body of the testicle immediately in front of the globus minor and entirely within the tunica albuginea of the gland proper; while the globus minor was to all appearances quite normal. And the microscope (specimen exhibited) demonstrated the growth to be a spheroidal-celled carcinoma. The upper end of the testicle contained a calcareous nodule (discovered before removal) as large as a hemp seed, and this was attached to the deep surface of the tunica albuginea. Mr. Mower White further stated that the patient was now in good health, and that he showed no evidence of recurrence in the lumbar glands or elsewhere.

Dr. CAUTLEY referred to a similar instance in a man, *et.* 28. The case was at first regarded as tuberculous disease of the globus minor of the epididymis, but, on operating, a small tumour was found in the lower end of the testis. This proved to be a columnar-celled carcinoma. In view of the fact that secondary dissemination occurred in the glands about the coeliac axis and in other organs, in eight to nine months, he asked what was the variety of carcinoma in the present case, and how the variety would influence the prognosis?

Mr. WHITE replied.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING AT THE LIVERPOOL MEDICAL INSTITUTION,
FRIDAY, OCTOBER 20TH, 1899.

The President, DR. DONALD, in the Chair.

SPECIMENS.

DR. STUART ROSS showed the specimen from a case of retroflexion of the gravid uterus, which terminated fatally from uræmia. The patient was pregnant 3½ months, and had retention of urine for one week. Six pints of very fetid ammoniacal urine were drawn off and the uterus replaced readily. The patient however, became comatose, and died 48 hours later, of uræmia.

DR. GRIMSDALE showed the specimen from a case of uretero-vaginal fistula following vaginal hysterectomy. Following this operation the patient had incontinence of urine and attacks of pain and swelling in the left lumbar region. A papilla could be seen in the vault of the vagina, and along this a sound was passed which led into an abscess cavity in the broad ligament, and into this the upper end of the ureter opened. The left kidney was much enlarged, and the seat of degenerative change with pyelitis. The exact condition of the parts was only made out after an exploratory abdominal section and the introduction of an ureteral catheter. While considering the question of a further curative operation, the patient suddenly sank from uræmia.

DR. BRIGGS showed some gynecological specimens.

CASES.

DR. BUCKLEY read the notes of a case of tubal abortion associated with a parovarian cyst on the opposite side. These were successfully removed by abdominal section.

DR. DAVIES related a case of ovarian tumour complicating pregnancy and labour. The patient had a difficult instrumental delivery, followed by severe pyrexia and signs of general peritonitis. An ovarian tumour was diagnosed, and abdominal section performed a fortnight after delivery. The tumour had undergone torsion of the pedicle, and was very adherent. The patient made a good recovery.

DR. GEMMELL related a case of hydatid tumour of the omentum removed by abdominal section from a patient who had recently been delivered of a full term child. The tumour was first discovered during labour when it occupied Douglas' pouch and caused obstruction. It was, however, readily pushed up by manipulation, and the child delivered naturally.

DR. WILLIAM ALEXANDER read a note on "The Treatment of Adherent Retroflexion of the Uterus by shortening the round ligaments." He pointed out that this operation was usually considered to be unsuitable for cases complicated by adhesions. In these cases he advised that posterior vaginal section should be performed and the fundus uteri liberated from its adhesions. The round ligaments could then be shortened in the usual way. He related three cases successfully treated in this manner.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.

MEETING HELD THURSDAY, OCTOBER 26TH, 1899.

The newly-elected President, Dr. J. Ivor Murray, J.P., of Scarborough, having been introduced by the retiring President, took the chair. He referred to the lamented death of Dr. Sinclair Coghill, of Ventnor, who died a few weeks after his election as President in June last.

Votes of thanks were passed to the retiring President, Dr. Fortescue Fox, the Editor of the "Journal," Treasurer and Auditors, the Librarian, and the Council and Secretaries.

The President then delivered an address, entitled:—

A RETROSPECT AND FORECAST.

Dr. Murray took a retrospective survey of the changes in medical practice during the 55 years of his profes-

sional career. Looking to the future he considered that the revival which had taken place in the value ascribed to the study of balneology and climatology, more especially in our own country and to which our Society might fairly claim to have contributed in no slight degree, was a matter of congratulation. Much was to be achieved by hygiene, baths, and mineral waters, and by the selection of the most suitable health resorts, and in the majority of cases this could be achieved as effectually in our own country as by exiling patients to foreign parts, and that with all the home comforts so imperfectly understood abroad, but which make all the difference to the invalid and to the chances of his recovery. The Fellows should bring before the notice of the society the advantages possessed by our own health resorts so that our brethren might become acquainted with the treasures which Nature has so abundantly supplied in various parts of the kingdom, and of which, in many cases, they were ignorant. It was only in this way that the prejudice which still existed in the minds of the great mass of our countrymen could be overcome. The attention which had recently been directed to the prevention of tuberculosis by rational outdoor treatment was peculiarly the province of this Society to study and encourage, and so with our prophylactics and means of treatment, of which balneology is not the least important, we might anticipate the time in the near future when human life, vastly extended, might be only limited by natural decay or accident.

DR. SYMES THOMPSON proposed, and Dr. McCLURE, of Cromer, seconded a vote of thanks to the President for his address.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, October 20th, 1899.

STUTTERING.

At the Academie de Medicine, M. Jonnesco, of Bucharest, related the case of a child of thirteen who was afflicted with pronounced stuttering, in whom existed also asymmetry of the cranium, with corresponding flattening of the left side of the head. Hemispherectomy, with resection of a portion of the bone and incision of the dura mater, was practised. The child got well at the end of a fortnight, and since then it has no difficulty in articulating. That fact seemed to prove that stuttering could originate from cerebral compression due to an arrest of development of the cranium.

CEREBRAL SURGERY.

At the Surgical Congress, M. Mondot said he had removed a bullet which had remained three years and seven months in the brain, from a man of forty-five whose mental trouble became so accentuated that he had to be placed in an asylum. The projectile was found buried in the brain tissue at a depth of an inch and a half. The man made a good recovery, and all mental disturbances completely disappeared.

The speaker practised also with success trephining in a man of twenty-three who, from a fall on the head suffered for several years from Jacksonian epilepsy, having as many as seven or eight attacks daily. The trepan was placed over the old cicatrix, and the bone was found to be twice as thick over the seat of the primary wound as elsewhere. The operator enlarged the opening to the limit of the abnormal thickness, and since the operation the epileptic seizures had not returned.

RESECTION OF THE SYMPATHETIC.

M. Vidal spoke on the indications and counter-indications of resection of the sympathetic in generalised

essential epilepsy. Resection of the sympathetic was physiologically justified when cerebral anæmia could be considered as an auxillary factor in epileptic phenomena. Certain toxic epilepsies seemed certain to derive benefit from resection of the sympathetic, for intoxication too slight to provoke an attack might be aided by mechanical irritation of the sympathetic. The operation on the other hand, was absolutely counter indicated in epilepsy provoked by cerebral compression, for it increased first the volume of the brain, and secondly the serious oedema so frequent in such cases. The difficulties in the diagnosis of essential epilepsy rendered necessary, as regards the counter indications of resections, the use of nitrite of amyl which produced temporarily the effects of resection. The operation should be reserved for subjects influenced beneficially by the inhalations made during the prodroma of the attack, and it appeared indispensable to abstain from it if the nitrite of amyl aggravated or provoked the attack.

RESECTION OF THE ILEUS.

Professor Tedenat said that he operated on a man of forty suffering from tuberculosis of the intestine. He removed five inches of the last portion of the ileus, and then united the intestine to the cæcum. The patient made a rapid recovery. Two other patients were similarly treated with an equally successful result.

TREATMENT OF CONJUNCTIVITIS.

Dr. Darier, of Paris, strongly recommends in the treatment of conjunctivitis the application of protargol, which contains only 8 per cent. of silver, while the nitrate contains 65 per cent. Consequently, the solutions employed for cauterising should be much stronger than if the latter agent were used.

For instillations the following formula might be recommended in the majority of cases: Protargol, ten grains, water 5ijss. A few drops to be instilled three or four times daily. For cauterising with a brush, the solution should be considerably more active; protargol 5j, water 5ijss. Insufflation of the powder might be employed in grave cases, such as blennorrhagic ophthalmia and trachoma, followed by massage of the lids.

M. Darier treated exclusively with protargol 500 cases of different varieties of conjunctivitis without the slightest accident; it is, in fact, an inoffensive agent.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, October 21st 1899.

ELEPHANTOID AND ULCERATIVE CHANGES IN THE EXTERNAL GENITALS AND RECTUMS OF PROSTITUTES.

An article by Victor Bandler in the *Archiv f. Dermat. u. Syph.* treats of this subject. The author says that these changes are not infrequent on the person of older prostitutes, that they cannot be classed among the known diseases, and that their etiology is not at present clear. Such torpid, deep destructions, with hyperplastic new formation attack by preference the posterior commissure, then the urethra and labia, the anus and rectum. In the latter-named situation they often lead to fistulæ and strictures, when they do not cause serious symptoms, are generally only discovered on digital examination. The author, who has observed a series of

such cases in Prof. Pick's klinik, is of opinion that these changes are always due to syphilis: the favourable effect of mercury on them is in favour of this view, and also the circumstance that they can often be traced to a primary infection. But the syphilis is only the primary cause for their development, disturbances in the lymph current, traumata, and irritations, also bear a part.

MEDICAL STUDENTS IN GERMANY.

The University Calendar recently issued by Professor Aschirson, shows that in the summer term the numbers of the medical students at the different universities were as follows:—Munich heads the list with 1,398, Vienna, 1,104; Berlin, 1,093; Würzburg, 623; Leipsic, 617; Freiburg, 508; Kiel, 444; Erlangen, 388; Gratz, 376; Zurich, 350; Bonn, 337; Strassburg, 332; Griefswald, 317; Breslau, 302; Heidelberg, 298; Geneva, 277; Giessen, 272; Tübingen, 271; Marburg, 267; Königsberg and Berne, 247 each; Göttingen, 233; Halle, 231. In Jena the number was 190; in Lausanne, 158; in Basle, 128; Rostock, 113; and Czernowitz, 4.

THE TREATMENT OF PHOSPHATURIA.

Professor Klemperer treats of this important subject in the *Therapie d. Gegenwart*, 8 99. By phosphaturia is meant the excretion of a urine that is rendered milky by precipitation of earthy phosphates. Phosphate of lime is always deposited when the relations of acid phosphates are not in proportion to the alkaline, in other words, when the normal reaction of the urine changes to the alkaline. Vegetable food makes the urine alkaline, as the vegetable acids become converted into carbon salts. It is clear, therefore, why phosphaturia comes on after free indulgence in vegetables and fruit. When a large quantity of hydro-chloric acid is secreted in the stomach, there is less at disposal for the urine; after a hearty meal, even if of meat, if urine is passed one or two hours after, slight phosphatic cloudiness is easily noticeable. As nervous people pass urine more frequently than others, occasional phosphaturia will probably be more frequent with them than others. It is further known that after violent vomiting and after washing out of the stomach, when a large quantity of hydrochloric acid is expelled, phosphaturia is liable to occur, and also in cases of dilatation of the stomach and motor insufficiency, when the acid contents are retained an undue length of time. All these conditions are met with in neuræsthenics, and it is therefore understood why phosphaturia is frequent with this class of patient.

The treatment of phosphaturia must have the aim of increasing the acidity of the urine. Above all, Minkowski advises albuminous foods (meat, eggs, cheese, cereals, and legumes), as they render the urine acid, and objects to potatoes, roots, and green vegetables, as well as fruit, as they make the urine alkaline. Without denying the value of dietetic treatment, the author believes that the treatment must act on the course of the phosphaturia, and that it can be successful only when it combats the nerve disease which causes hyperacidity and sleeplessness. The treatment of phosphaturia is therefore not easy, and cannot be carried out according to a rigid scheme. No dietetic and no medicinal prescription are of unusual utility. The art of the physician should select a régime that corresponds to the nervous energy of the patient, and a great deal will be in the moral treatment. The author has treated his patients with a free and mixed dietary, and independently of

meals has recommended them a large quantity of water, especially frequent acidulated drinks. He has frequently made use of electricity and hydrotherapeutics. He has sent many to the sea-side and some to mountain residences. He has impressed upon them that they suffer from a nerve disorder, the treatment of which will be materially aided by great regularity of living and self command.

The same journal contains an article by Professor Ewald, on

ORGANO-THERAPEUTICS, ARSENIC, AND THYROID PREPARATIONS (IODOTHYRIN).

The Professor, who has contributed largely to the building up of thyroid therapeutics, believes that they have gained a firm place in our *materia medica*. The employment of thyroid preparations would have been more extensive, but for certain bye-effects which act as a set off. To these belong the nervous disturbances, sleeplessness, pains in the head and limbs, in the lumbar region, oppression, palpitation, acceleration of pulse, loss of appetite, vomiting, diarrhoea, rise of temperature, and sometimes the appearance of albumen and sugar in the urine. As the symptoms sometimes exhibited have been alarming, and as death has actually followed the use of this preparation, the communication made by Mabilie, of Rheims, that this thyroidism could be avoided, or to a great extent limited by the simultaneous employment of arsenic came as a great relief. The author has given the combination in four cases of idiopathic struma, and one case of obesity in hospital, one case of infantile myxœdema, and one case of struma in private practice. The iodothylin tablets (Elberfelder Fabrik, Bayer and Co.) contain 0.25 grms. each. One or two were given for a dose at first, and the increase was one daily until eight or ten were given. The arsenic was given in the form of Fowler's solution or arsenious acid pill (1 mgrm.), the dose of this also being increased daily. The results were good in the struma cases; that of infantile myxœdema was not long enough under observation for an opinion to be formed.

Although large doses of iodothylin were given, no disagreeable bye-effects were observed in any case, without arsenic they might have been expected almost with certainty. With the exception of slight acceleration of the pulse (up to 110), neither objectively nor subjectively were any symptoms of thyroidism observed; so that the impression could not be excluded that arsenic was really a powerful corrective of thyroidism, more certain and more regular in its action than atropine.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, October 28th, 1899.

OPERATIVE TREATMENT OF TUBERCULOUS PNEUMOTHORAX.

At the Gesellschaft der Aerzte, Anton Drasche related the history of 230 cases of pneumothorax which he had recently treated, 32 of which were non-tuberculous. Of the 198 tuberculous cases 168 were treated symptomatically, the other 30 surgically by puncture, aspiration, costo-section and washing out of the pleural cavity with ordinary saline solution. The surgical treatment gave 12 per cent. of satisfactory re-

coveries, while the expectant treatment only gave five, although the latter in no case presented grave symptoms such as cyanosis, small pulse, laboured breathing, &c. The surgical treatment is more important when prolonged suppuration is exhausting the organism, and leading to the formation of bands of adhesions in the lung. It is always important, from a surgical point of view, to know whether the lung fistula is open or closed. The differential diagnosis of Unverricht and Weil, who maintain that the open fistula in pneumothorax gives a water piping sound, is not to be relied upon as diagnostic, as other large cavities will produce a similar phenomenon. They think the most distinctive sign is the analysis of the pent-up gases, as oxygen and nitrogen are rapidly absorbed, while the quantity of CO₂ is high. A relative increase of CO₂ over ten per cent. points to a closed fistula, while below five per cent. it may be assumed to be still open. As a general rule, the fistula remained opened for two or three weeks.

MORBUS BASEDOWII.

At the Versammlung, Sitmann reviewed the history of Graves' disease since 1893, a period which he said had been barren of any therapeutical improvements. Pathological anatomy showed the thyroid gland to be the source of the disease, but Askanazy went further and attributed the disease to an alteration or fatty atrophy of the striped muscles, which would to some extent explain the various phenomena of the disease, but it failed to elucidate the tremor. Physiological examination showed a more active transformation of the nitrogenous material which might favour the muscular change. The sympathetic theory has again been revived in France, as well as the theory bearing on the central nerve-system, both of which have their advocates, but both of these theories fail to throw light on the exact morbid condition of the thyroid. Again, we have a compromise in the thyrogenic theory being combined with the central nervous system, which has a tendency to lower the nutritive supply. From this we infer that the battle is between the thyroid and the central nerve organs, but the question as to which is the primary lesion, is not yet settled. Sitmann considers that the clinical features point to a combination of factors, viz., central nerve organs, connecting links such as the sympathetic, the vagus, and the end organs which are brought into collateral sympathy with the nutritive apparatus—the hæmatic system. A lesion in any one of these three factors would probably produce a specific alteration in the thyroid gland. It is therefore necessary to consider which symptom has been the most prominent in this complex arrangement in seeking to determine the primary lesion.

Rehn thought the thyrogenic theory was proved by the results of surgical treatment. The lesion of the gland was admitted to be the principal change in the disease, though it might not always be outwardly marked. It mattered not if the whole gland or part of the gland were affected the characteristic changes are the same. The prognosis of the disease must be cautiously approached; spontaneous recovery sometimes takes place quickly, other times slowly, but this cannot be relied on as constant. The fatality of operation is due to (a) The severity of an operation entailing the removal of a large hæmatic

gland; (b) The low resistance of the enfeebled patient; (c) The presence of *thymus persistens*. The operative treatment not only effects an improvement in all the symptoms, but often brings about permanent recovery from the disease. He divided his case into three groups. First resection of the gland 177 cases, of which 57.6 were cured, 26.5 per cent. improved, 2.3 per cent. remained unchanged, while 13.6 per cent. died. Of the second class, of resection of the sympathetic there were 32 cases in all; 28.1 per cent. were cured, 50 per cent. improved, 12.5 per cent. remained unchanged, while 9.3 died. The third class, of arterial ligation comprised 14 cases, 2.4 per cent. recovered, 5.7 per cent. were improved, and 28.6 per cent. died. Of the 319 cases treated the average results were 51.8 cured, 27.9 per cent. improved, 4.1 per cent. unchanged, and 13.1 per cent. died. The lesson to be learned from this experience is the great danger of the method by ligation of arteries.

Every case should be first treated internally with some of the thyroid preparations. In the cachectic stage the operation gives little hope of success. Operation should be undertaken whenever the gland pressure is high or the presence of malignant cysts suspected. The existence of nodules of hard consistence will decide any doubt. Operation without narcosis is to be preferred.

The Operating Theatres.

MIDDLESEX HOSPITAL.

AMPUTATION OF THE PENIS FOR EPITHELIOMA.—Mr. A. CLARK operated on a man, æt. about 50, who was the subject of an epithelioma of the penis, which had developed on the top of a sloughing syphilitic chancre. Mr. Clark said that the patient had been under his observation three months ago, when he was admitted to the hospital on account of a rash on his body, and a discharge from a phimosed foreskin. The rash was obviously syphilitic, and a cursory examination of the penis demonstrated the fact of an indurated chancre beneath the foreskin. There were amygdaloid glands in both groins, and the lymphatic glands at the back of the neck were also enlarged. The patient was immediately put on anti-syphilitic treatment, the foreskin was slit up, and the chancre, which was found to be sloughing, exposed and actively treated. The patient began to improve at once, and in a month appeared to be on a fair way to recovery. The sore, however, did not quite heal, and in about a month and a half the induration began to recur, and the ulceration to extend to the tip of the glans. The patient's general health, however, seemed to improve, and the enlargement of the lymphatic glands decreased. The induration continuing to spread, the suspicion of epithelioma was confirmed by microscopical examination, and the patient was advised to sacrifice the organ; to this he consented after a little delay. Accordingly, nearly four months after his first admission, the patient was anaesthetised, and the penis removed by the flap operation. The root of the penis having been constricted by an india-rubber tourniquet, a broad dorsal flap, including the skin and subcutaneous tissue, was dissected up on the dorsum of the penis, and a smaller flap from below, the corpora cavernosa were then divided, and the tissues dissected off the urethra for about one-third

of an inch in front of the division of the corpora cavernosa, and here the urethra was divided. The tourniquet was taken off, the vessels secured, and the bleeding stopped with very little trouble. The projecting urethra was then slit horizontally, the upper portion being sewn to the upper flap and the lower to the lower flap. The skin flaps were then joined over the rest of the wound and a catheter tied in to the bladder. Mr. Clark said that the development of epithelioma on the top of a chancre was uncommon, but in this case the recurrence of the induration which did not yield to treatment suggested the use of the microscope, which demonstrated the case to be one of epithelioma. He pointed out that the prognosis in these cases was more favourable than in most cases of malignant disease, recurrence being the exception rather than the rule, both in the organ itself and in the lymphatic glands, especially when the operation was performed at an early period, as in this patient, before the disease had extended to the lymphatic glands.

ST. GEORGE'S HOSPITAL.

ABDOMINAL TUMOUR.—SEROUS CYST BEHIND THE RIGHT COLON.—Mr. HERBERT ALLINGHAM operated on a woman, æt. 30, who had a fluctuating tumour in the right side of the abdomen about, but not beneath, the kidney region. The abdomen was opened in the right linea semilunaris, when the tumour was found to be behind the colon, having no connection with the kidney or with the pelvic organs. The colon and peritoneum were turned over towards the middle line; the lump was then found to be a serous cyst; this was tapped and the cyst wall enucleated. The fluid appeared to be only ordinary serous fluid; there were no hydatids; it was more like the fluid of a parovarian cyst. After the cyst had been removed the colon and peritoneum were replaced, and the abdominal walls sewn up in the usual way. Mr. Allingham remarked on the curious fact that the patient should have such a cyst, not connected with the pelvic organs, or with the kidney situated behind the ascending colon. It shelled out easily, he said, like an ordinary broad ligament cyst. He did not think he had ever heard of a parovarian cyst being in such a region though undoubtedly this tumour was more like a parovarian cyst than anything else.

ANEURYSM OF THE UPPER THIRD OF THE RADIAL ARTERY. REMOVAL OF THE ANEURYSM.—Mr. Herbert Allingham operated on a man, æt. 45, a blacksmith, who had noticed about two months before admission, after a strain, a sudden pain in the upper part of the forearm followed by swelling. The swelling increased, and on admission it had all the character of an aneurysm. An Esmarch bandage having been applied, a long incision exposed the tumour which was found to extend deeply into the muscles of the forearm. The whole aneurysm was dissected out. The interesting point, Mr. Allingham said, was that, on after dissection, it appeared that the radial artery had been torn right across, and the aneurysmal sac had been formed in and about the muscles of the forearm. The removal was very difficult, as it was troublesome to free the so formed sac from the muscles. Mr. Allingham remarked that it was an uncommon condition, as the aneurysmal sac was entirely formed in the muscles, no part of the wall of the vessel entering into the formation of the aneurysm. He pointed out that during removal the

large amount of blood clot made it a possibility that the tumour might be a pulsating sarcoma, it was, in fact, only definitely settled it was an aneurysm after it had been removed and carefully examined.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR A SERIES OF INSERTIONS:—Whole Page, thirteen insertions (weekly, fortnightly, or monthly), at £3 10s. 6d.: twenty-six insertions (weekly or fortnightly) at £3 3s. 0d.: fifty-two insertions (weekly) at £3 each. Half Page, thirteen insertions at 35s.: twenty-six at 32s.: fifty-two insertions at 30s. each. Quarter-page, thirteen insertions at 18s.: twenty-six insertions at 16s.: fifty-two insertions at 15s. each. One-eighth page thirteen insertions at 9s.: twenty-six insertions at 8s.: fifty-two insertions at 7s. 6d.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d.: Half Page £2 10s. 0d.: Quarter Page, £1 5s.: One-eighth, 12s. 6d.

Small announcements of Practices, Assistantships, Vacancies, Books, &c.—Seven lines or under, 4s. per insertion; 6d. per line beyond.

Letters in this Department should be addressed to the Publishers.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 1, 1899.

THE FUTURE OF MEDICAL SOCIETIES.

THE future of our medical societies is a matter which nearly concerns all who are interested in the advancement, as distinct from the practice, of medicine. It is common knowledge that each year the task of keeping up the supply of papers for discussion is becoming more and more onerous, and we can recall divers occasions on which only the readiness of speech which characterises the honorary secretaries has prevented the collapse of the proceedings. The blame for this state of things is attributed to the medical journals which greedily absorb all the literary work with any pretensions to merit which they can lay their hands upon, but this process of absorption is rather a symptom of the disease than the disease itself. If we compare the prompt publicity which a medical journal can offer to the author of a communication with the limited and tardy publicity which the average medical society provides, no surprise can be felt at the preference which the workers in the field of medical science display for the former. This is a point of view which does not appear to have received the attention it deserves by the managers of these societies, who blindly adhere to articles of association which were evolved when medical journalism occupied a position in the medical world very different from the predominant place it has acquired during the last half century. Another cause of the dearth of papers is the multiplication of societies far beyond the requirements of any class of practitioners. The late Sir Andrew Clarke must have had an inkling of this when some years ago he devoted his waning, but

still valuable energies, to the creation by federation of an Academy of Medicine for England. Whether, if he had been spared, he would have been enabled to realise his plans we know not, but his disappearance sounded the knell of the project. Something, however, has to be done, and that promptly, if scientific bankruptcy is to be averted. Existing societies look upon federation much in the same light as the British public look upon compulsory military service—viz, as a thing that may become unavoidable, but which for the time being is to be avoided at any price. Short of this drastic but reasonable measure it ought to be possible to devise improvements calculated to revive interest in these gatherings. The institution of clinical evenings, copied from the Clinical society, has everywhere proved an unqualified success, though the interest of the living specimens is not always on a par with their number. But clinical evenings must necessarily be the exception, and there remains the difficulty of providing subjects for discussion. It is really time that those who are responsible for the conduct of existing medical societies appreciated the fact that writers of papers resent the general rule forbidding them to publish their contributions in the medical journals under penalty of risking exclusion from the "Transactions," which are only published after a long interval of time, and when issued, only come before a comparatively limited number of readers. Even if the advancement of science alone be considered—though this is by no means the only motive which authors have in view in laboriously compiling the results of their researches, it seems absurd that possibly valuable results should be held over in deference to a mistaken and narrow idea of literary property. It may even be asked whether the interests of the debate would not be better served by the previous publication of important papers in the journals, for this measure would enable fellows to think the matter over beforehand, and to prepare observations and reminiscences worthy of the occasion. It is not given to everyone to grasp the tenour of a long paper delivered at break-neck speed by an amateur reader, nor can the majority of men prepare and deliver on the spur of the moment a clear account of what they know on the particular subject. This difficulty has been so far recognised by the Royal Medical and Chirurgical Society that the papers are printed in advance, so that intending speakers can take cognisance thereof beforehand. To publish them in a medical journal before the date of the meeting would be but a step, and would certainly fulfil the object in view vastly better as well as more economically. The so-called abstracts, which it is the custom to hand round at certain societies, utterly fail to fulfil their object. Prepared for the most part by men who have no experience of *précis* writing, they are practically worthless, and merely cumber the society reports published in the journals with a lot of matter which is not detailed enough to preface the discussion that follows. Some societies, like the Ophthalmological, do not court publicity, but

in a society of specialists this is not of much importance, because the subjects treated there are far too technical for the ordinary reader

OPERATIONS UPON LUNATICS.

ALTHOUGH of late years cases have been from time to time recorded of operations upon lunatics, the series published by Mr. Paul Bush, in the *Bristol Medico-Chirurgical Journal* for September, is interesting, inasmuch as there was nothing in the nature of the cases to show that the mental condition of the patients depended upon the diseases present. In all, five lunatics were operated upon, and each made a good recovery, both mentally and physically. In one a young lady had been under restraint for three years; she was also suffering from two bad ingrowing toe-nails. These were removed and within three months she had quite recovered her normal mental condition. In another, a lunatic man, æt. 70, was a sufferer from cystitis and dysuria, caused by a stone in the bladder. A supra-pubic operation was performed, and a calculus two inches long and one inch thick was extracted. After the operation, his mental state began at once to improve, and in mind and body the patient was cured within six months. The third case was that of a woman, who had been for two years and a half in an asylum, for melancholia and severe suicidal impulses. A year after her admission she had retention of urine and intermittent attacks of menorrhagia, which continued for six months. Examination revealed a large solid growth reaching from the pubes to the level of the umbilicus. This was found to be due to a uterine fibroid and was removed *per vaginam*. The patient made an uninterrupted recovery, and in less than six months was discharged from the asylum with her mind quite restored. The fourth case was also that of a woman who, on her admission was acutely maniacal. After some weeks she complained of severe epigastric pain with temporary collapse; from this attack, however, she rallied, and for ten days appeared better. Then rigors suddenly supervened and a swelling was made out in the epigastric region. The swelling proved to be an abscess, from which a pint of pus was let out, but there were signs of septic peritonitis, and her recovery seemed almost hopeless. Nevertheless, despite everything, the patient did well, and was discharged seven months later, sound in health, and quite sane. The last case was that of a woman, æt. 32, who had been under treatment for two years, suffering from severe suicidal and homicidal impulses. A year before she was operated upon there was a history of her having swallowed needles, and complaints had been made by her of attacks of severe abdominal pain. Ultimately the pain became persistent, vomiting supervened, great loss of flesh ensued, and a hard tumour was made out in the epigastric region. The stomach was opened, and four hatpins extracted. Three months after the operation the patient was

discharged from the asylum quite well, both in body and mind. The brief notes here quoted of these interesting cases all indicate that the deranged mental faculties of the patient became manifest long anterior to the time when the interference of the surgeon was demanded. That is to say, it is presumable that the conditions which showed the necessity for surgical relief were independent of the cause of the madness. In reflecting upon the fact, then, that the operations undertaken for the relief of the various conditions present should have also been followed by the restoration of the mental faculties, one cannot avoid raising the question as to the etiology of the mania. It is scarcely possible to believe that the mental disquietude could have been due to an organic cause, that is to say, to any gross change of tissue in the nerve centres. On the other hand, if this hypothesis be admitted, the only alternative to fall back upon is the assumption that the mania was functional in character, and only wanted some sudden outpouring of nerve force in order to restore the mental equilibrium. One point in these cases is certain—namely, that the operation performed not only cured the body but cured the mind, and, therefore, it is quite possible that its indirect influence for good was conveyed through the nerve system. These cases undoubtedly throw an interesting light upon the practice of surgery among the insane. Perhaps it may be that at this moment there are many persons under restraint in our asylums who only require the counteracting effect of an operation to restore them to sanity. But unless the indications for operating happened to be present it would scarcely do to experimentalise in this direction in order to test the value of the hypothesis. However, the matter is one which might well claim the attention of our asylum medical officers.

THE HISTOGENESIS OF NEOPLASMS.

DURING the last few years evidence has been accumulating in favour of the view that cancer is a communicable disease, not only from site to site in the same individual, but from one individual to another. Moreover it has been shown to be possible to induce in animals by direct inoculation, growths which, clinically and microscopically, must be classed as malignant. Now that veterinary science is waking up, and is gradually being placed on a more scientific footing we may hope that the next few years will add to our knowledge in this respect. Already one class of growth formerly included among the sarcomata, actinomycosis to wit, has been recognised to be a parasitic disease and the occurrence of malignant growths in the lower animals, long a matter of doubt, has been satisfactorily established. These important points having been cleared up it remains for investigators to determine the exact nature of the *materies morbi*. No particular organism has as yet been identified in causal relationship to cancer, and all experiments made in this direction hitherto have been carried out with cells taken from an infected area in fact this

transplantation of cells must, for the present, be regarded as indispensable to infection. Hypothetically it is assumed that the exact form of the primary growth, *i.e.*, the original infection, is determined by the character of the tissues at the point where the infection gains an entry, and that the secondary infections, being caused by the transmission of the actually diseased cells, preserve the original type though their histological structure may, in a slight degree, be modified by conditions of environment. Should this secondary infection by chance take place apart from the transmission of the actual cells, there is no theoretical necessity for the secondary growths to follow the original type. It is urged that for purposes of investigation, a distinction should be made between connective tissue and epithelial growths, but it is difficult to base a distinction on purely histological variations in view of the clinical resemblances which characterise the typical growths of both forms of tumour. We are quite prepared to learn later that some of the growths at present classed as cancer are due to bacteria, in other words, that in some cases the hyperplastic process merely represents the reaction of the tissues to irritation set up by living bacteria. The tendency to unlimited multiplication of infected cells, and their ability to maintain their histological characteristics, even in other situations, constitute a very special pathological feature, for which there is no parallel in other morbid processes. It is this peculiarity which has, so far, baffled all attempts at elucidation.

Notes on Current Topics.

A Study of Anger.

IN a recent number of the *Psychological Review* Mr. G. Stanley Hall gives an interesting account of what we may call the physiology of anger. Anger may be defined as the outward and visible manifestation of emotions which have escaped control and the measure of individual civilisation is precisely the degree to which command over these particular manifestations has been acquired. The "gentleman" is conventionally one whose nervous system has been so disciplined as never to elude control in this direction. In a state of nature no control of the kind is practised except in deference to motives of a physical order, but the further we advance on the path of civilisation the more the ability to command the emotions is expected and enforced. If this be so it is difficult to avoid the conviction that we have not advanced very far on that road. Each individual has his weak side, in other words, everyone is more vulnerable on one point than on certain others. Some people are peculiarly susceptible to ridicule, while others are more disposed to jealousy, a sense of injustice or disappointment. The manifestations of the state of anger vary according to the temperament of the individual, but in all there is grave circulatory disturbance, occasionally so marked as of itself to determine a fatal issue. Those in whom the heart is

strong and prompt to react, usually flush at the approach of anger, but the less sanguine, and those whose hearts respond less readily to stimulation, or are unequal to the strain thrown upon them, become pale, though the pallor may be but momentary. In both the force of the heart beat is markedly enhanced, the heightened blood pressure accelerates the urinary and salivary secretions, while the greater demand for oxygen causes active working of the respiratory muscles. The extraordinary strain thus thrown on the nervous system is apt for the time being to disorganise the muscular apparatus, leading to tremors and unsteadiness of gait, which, however, may be promptly recovered from. Giddiness, nausea, and other functional disturbances are directly attributable to the sudden change of blood pressure. The sounds emitted by persons under the empire of anger vary, passing from the monotonous cry of infancy, through the animal-like noises of childhood, to the threats and oaths of adult life. In exceptional cases there is a kind of inhibitory paralysis of the sound-producing apparatus, but in general the emission of a noise of some sort seems to be the necessary accompaniment of this state of pent-up energy. The state which we call irritability results from impairment of the inhibitory powers, and is often due to ill-health or to fatigue and loss of sleep. The irritability of convalescence is a sign that the lower reflexes are restored before the higher for the "department of inhibition" is the controlling power of the organism and the seat of the highest manifestations of the *ego*.

The Primate on Medical Training.

THE Archbishop of Canterbury, in the address with which he heralded the distribution of prizes at St. George's Hospital Medical School last week, opportunely insisted on the fact that, although accident occasionally paves the way to scientific discovery, the great mass of discoveries come from hard study. Even in the cases of so-called accidental discoveries the result in a very large number of instances has turned upon previous knowledge, without which the significance of the accident, which proved the starting point of a quasi-revelation, would probably have been overlooked. The accident of the falling apple which started Newton thinking of the laws which govern the universe, was pregnant with meaning only to him, and so it is with the many 'accidents' which clinical experience brings before us. The uneducated or unobservant person has eyes yet sees not and the vast majority of human beings see only, and then imperfectly, what they have been trained to see, and their mental vision stops at the threshold of the unknown. By persistent study alone can we hope to acquire the knowledge which shall enable us to recognise the precious stone when chance throws it in our path. Knowledge may be described mathematically as a line, finite at one end and infinite at the other, so that our course must be ever onwards under penalty, as His Grace so pithily put it, of going back. The man, he observed, who stands still in medicine is losing ground and

is beginning to go back. The world is moving onwards, and unless we move with it we are indeed falling behind. The task is harder for each succeeding generation, for the new comer has first to master what has already been accomplished before he can apply himself to the task of adding to the store. The life of the medical practitioner is, or ought to be, one of perpetual study. His training merely teaches him to observe, and his subsequent experience should enable him to learn. Experience is not knowledge, otherwise the oldest among us would be the wisest *quod absurdum est*. As long as we practise medicine and surgery we ought to continue to study medicine and surgery in gratitude to those who have laboured on our behalf in the past, and as evidence of our desire to maintain an exalted conception of our profession.

Miscegenation.

THERE is a general impression, based on wide experience, that half-castes are necessarily inferior to the two races which produce them, but on looking into the matter the impression would seem to be fundamentally erroneous, although the observation may, in the main, be correct. The fact probably is that half-castes are usually the results of illicit connections, and are consequently brought up under conditions of environment unfavourable alike to physical and mental development. A similar remark might be made concerning illegitimate children everywhere, and obviously the deterioration so frequently observed in them must be due, not to any inherent incapacity, physical or moral, but to the influence of pernicious surroundings. There are many examples of half-caste races which occupy a high position in the scale of humanity—not to go further than the Brahmins and the clans of Rajpootana—races descended from men who left their homes before the white invader and intermarried with the dark women of the plains. The antipathy of white people towards such unions is, however, readily comprehensible for it means degradation for the offspring as compared with their white sires, while, on the other hand, the readiness with which coloured women ally themselves with whites is physiologically justified by the prospective superiority of the offspring as compared with the maternal strain.

The Reorganisation of International Congresses.

THE recent congress which took place at Amsterdam has given rise to much editorial criticism on both sides of the Atlantic of the system which prevails in the organisation of such gatherings. It seems that it was originally intended to restrict the papers and discussions to those who had been formally invited to participate in the proceedings, but this otherwise admirable idea was overruled in view of the fact that the financial success of the congress would thereby have been imperilled. Nevertheless, we are disposed to believe that some such arrangement will ultimately come into force or these huge picnics will fall into discredit. The disproportionate import-

ance which the festive part of the programme has assumed of late years tends to minimise the real object of the gatherings which is, or ought to be, the advancement of knowledge. But even from a social point of view a measure which would tend to limit participation to those whose professional standing renders them worthy of the honour, need not react prejudicially. Municipalities and local bodies would doubtless show themselves much more hospitable if it were possible for them to keep their hospitality within reasonable bounds. It is fast becoming a physical impossibility for individuals, or aggregations of individuals, however hospitably disposed, to minister to the appetites of thousands, whereas if membership implied professional distinction, the numbers would be reduced to manageable proportions. The legitimate expenses attendant upon an assemblage of scientific men who have met for purely scientific purposes, need not be great, and the attractions which have become such a marked feature of the present-day congress are sought after and enjoyed more particularly by "everybody who chooses to attend." As the *New York Medical Journal* observes, the open door policy is the correct one if the object be to get the profession together and have a good time, but if the chief motive be to secure a consensus of opinion of the leading lights of a specialty, the side-shows should be eliminated and the membership restricted.

Gum-Paper as a Fatal Sticking-Plaster.

THE term, "stamp lickens" tongue, which the MEDICAL PRESS AND CIRCULAR was the first to use, has since become embalmed in the literature of the land. It is to be hoped that some good, from a preventive point of view, may result from the general attention that has been called to the matter, and that careful folk will, in future, wet their postage stamps by means of a moistened finger or a mechanical damper. It is clear that even were the adhesive stuff above suspicion, which it is not, that there still remains an abundance of ways in which a stamp may become contaminated. For instance, outside a post box not long ago, the present writer saw a man drop on the pavement a postage stamp, which he then picked up and applied to his tongue before fastening to the envelope, as if such things as dangerous germs were unknown in the dust of a London street. Postage-stamp paper, however, is not the only source of sticky mischief when applied to wounds. The gummed edge of an ordinary envelope may be just as fraught with evil. Only last week an inquest was held in London on the body of a clerk who used that substitute for sticking plaster to a wound in the scalp. The medical testimony was to the effect that death was due to septiciæmia, and the surgeon commented upon the un wisdom of putting gum-paper on a wound. Of course, there are various ways in which the wound may have become septic, but the use of the rough-and-ready method in question opened up risks that were no less terrible than unnecessary. Nowadays

in almost every household, it is possible to find some simple anti-septic, such as weak carbolic acid or permanganate of potash, that would be available for the immediate treatment of wounds.

The Carmichael Prize Essay.

IN our columns to-day will be found an announcement by the Royal College of Surgeons, Ireland, that it will, this time next year, award £120 for the best Essay on medical education as specified in the will of Richard Carmichael. This Prize has been in abeyance for some years past, because the College had found that the income of the Fund did not come near to providing the cost of carrying the trust into effect, and in fact, the College had lost heavily by the effort to do so. It was, therefore, decided to apply to the Master of the Rolls to amend the scheme for allocation of the income, and the College was anxious that the money should be applied to some professional purpose more useful than the publishing of an Essay on a subject so thread-bare as medical education, it having been found by past experience that expenditure on that object was absolutely useless. The Master of the Rolls, however, while he modified the scheme so as to make it workable, refused to change the purpose of the outlay as expressed by the testator, and it is accordingly now making a fresh endeavour to comply with a very irksome obligation, and to get some value for the heavy outlay.

The Death of General Symons.

THE nation has received with deep regret the news of the death of the gallant commander of the British forces in the battle of Glencoe. General Symons was originally reported to have been wounded by a bullet in the abdomen. From the first, the wound was described as a mortal one, and, therefore, the worst was anticipated. But reassuring news arrived last week that the projectile had been extracted, and that the wounded officer was beginning to progress favourably. The improvement, however, was only of temporary duration, and the announcement of his death was received in London at the end of last week. Thus another gallant, distinguished British officer has laid down his life for his country in the cause of freedom, justice, and humanity. We may be assured that everything was done for him which British surgery could effect. So far we are in the dark as to the exact nature of the lesion, nevertheless, nothing from the first could have been more wanting in hope than the announcement conveying the intelligence that the wound was mortal. The sympathy of the nation will be with Lady Symons, whose sad bereavement has been the object of so much public condolence.

AN outbreak of scarlet fever among the men of the Durham Light Infantry, who were under orders to sail for South Africa, has led to a change of plans, and it is probable that the regiment will be struck out of the list for active service.

The Care of the Sick and Wounded in South Africa.

MR. WYNDHAM, in the closing meeting of the session of the House of Commons last week made some reassuring remarks concerning the arrangements for the care of the sick and wounded in South Africa. At the present moment he stated that there were in Natal 44 officers and 263 men of the Royal Army Medical Corps, with five nursing sisters. Eight more officers and 80 men were due on the 26th ult., while there would be a total of 1 100 hospital beds in Natal, and 550 near Cape Town. In addition, two hospital ships had been sent out for the conveyance of the wounded from Natal to Cape Town. Moreover, further preparations were in progress in order to provide for contingencies, such as the demand which might fall upon the British Medical department of attending to a large number of wounded Boers. We are glad to note that the American ladies in London are raising a fund of £30,000 to provide a hospital ship to go to South Africa for the succour of the sick and wounded in the war. Altogether, so far, satisfaction may be felt in the arrangements made for the care of the British troops.

A Skin Hospital for Dublin.

A MEETING was held at the Hibernian Hotel, Dublin, on the 26th ult., for the purpose of promoting the establishment of a special hospital in Dublin for the treatment of skin diseases. There was an influential attendance, mostly of non-medical men, and resolutions were adopted, with acclamation, declaring the necessity for such an institution, and directing steps to be taken to organise it. Dr. C. M. O'Brien and Dr. George B. White are taking an active interest in this work.

Rehabilitation of the Ratcatcher.

DR. RAWLINGS calls attention in the *Times* to an interesting paragraph in *Defoe's Journal*, written at the time of the Great Plague in 1664. He says:—"An order was published by the Lord Mayor and the magistrates, according to the advice of the physicians, that all dogs and cats should be immediately killed. . . . A prodigious number of these creatures were destroyed. . . . Forty thousand dogs and five times as many cats. . . . All possible endeavours were made use of to destroy the mice and rats, especially the latter, by laying rats-bane and other poisons for them, and a prodigious number of them were also destroyed." This is interesting in view of what is now known concerning the rôle played by these rodents in the dissemination of the plague, and it is important because rats almost invariably form part of the cargoes of ships coming from infected ports. The occupation of the professional ratcatcher bids fair to be rehabilitated in the near future, and he may even aspire to become a sanitary official. We would suggest that the time that can be spared from the hunt after the bacillus tuberculosis might perhaps be advantageously devoted to the destruction of rats.

The Local Government Board and Boards of Guardians.

THE Local Government Board are having an exceptionally busy time just now with recalcitrant local authorities. Their war with the Leicester Board of Guardians is still raging, and they have in addition several other important cases in hand. Among these must be mentioned their dispute with the St. Olave's Board of Works. The latter body recently suspended their Medical Officer of Health, Dr. W. A. Bond, for having, in conjunction with the Suffragan-Bishop of Southwark, sanctioned the removal of some human remains from the crypt of the church of St. Thomas's, Southwark, without obtaining the permission of the authority of his district. The Local Government Board, however, having had the facts brought under their notice, directed the St. Olave's Board of Works to reinstate their Medical Officer. But this the latter peremptorily refused to do. The climax in the dispute was reached by the central authority in pursuance of their legal power, giving notice that they intend to issue an order to remove Dr. Bond's suspension. However, even this decision has had no effect upon the obstinate Board of Works. They have decided to adhere to their determined action in the matter, and the result, namely, their discomfiture, can, therefore, now be only a question of a few days. Sympathy must be felt for the Local Government Board that the local authorities whose action they have to control are not more generally composed of persons gifted with common sense and more alive to their duties as public officials.

The Postal Service and Vaccination.

IN consequence of many of the Post Office employees having been called out with the reserves for active service at the seat of war, the authorities at St. Martin's-le-Grand have had to deal with a large number of vacancies, and persons willing to undertake the duties of auxillary postmen have recently been in much demand. It seems, however, a good deal of difficulty has been experienced in filling up the vacant posts. There is no lack of applicants—though the payment is only six shillings a week—and the applicants fulfil all the requirements of height, character, and education. But they decline, a contemporary asserts, to submit to the clause requiring vaccination. That is to say that their misguided conviction upon this matter prevents them from obtaining employment for which they are otherwise quite suited. All that we can say upon this matter is to express the hope that the authorities will not give way in the demand for this necessary requirement for public service. If candidates for labour cannot or will not see that it is to their own interests to conform to the regulation in regard to vaccination, it is entirely their own fault if the consequences thereof are not to their liking. It is the duty of the State to see that the work of the State is not exposed to any risk of interruption, such as would be the case were an epidemic of small-pox to break out among its

servants who had been allowed to remain unprotected by Jenner's valuable prophylactic.

A Fatal Post-Mortem Wound.

LAST week an inquest was held upon the body of a medical man, Mr. W. G. Hull, M.R.C.S., who died at the London Hospital. From the evidence it appeared that the deceased scratched his hand accidentally while making a post-mortem examination fourteen days previous to his death. At the time, the injury was immediately treated with antiseptic lotion, but a fatal acute septicæmia ensued. This sad incident points to one of the dangers inseparable from the profession of medicine. Indeed, the wonder is that it is not a matter of constant occurrence, for whereas cuts and scratches are common in the course of post-mortem examinations, yet on the other hand general septic mischief is happily a rare result. For this fact the powers of individual resistance have no doubt to be credited to a great extent. There are certain prompt precautions, however, that are absolutely essential for the safety of the individual concerned. The wound had best be washed under the tap and sucked. It should then be rubbed with solid caustic, or better still with a liquid caustic, as pure carbolic acid. The wound should then be dressed with an antiseptic dressing, such as iodoform or corrosive sublimate until healed. By such vigorous measures the danger of a poisoned wound sustained at the post-mortem table will be reduced to a minimum. To neglect to treat even the slightest prick under such circumstances is the veriest foolhardiness. A good precaution is to touch all slight abrasions of skin with lunar caustic.

Smoke Prevention.

THE efforts of the world to work out its own salvation go towards the formation of history, but when gauged in any one particular direction are apt to seem hopelessly slow and feeble. Take the question of smoke prevention, as to the absolute evil of which to health and to property everyone has been convinced of for generations past. The volume of smoke vomited forth into the atmosphere of our great towns is just as vast as ever it was, if, indeed, not much greater in these later days of general prosperity. The causes of this persistence are not far to seek. Apathy on the part of the local authorities to prosecute factory owners, want of supervision by overworked sanitary inspectors, and the absurd leniency displayed in these cases by police magistrates. Fortunately for the future well-being of our citizens, signs have not been wanting that the days of the offending chimney owner will soon be numbered, that is to say, unless he be prepared to put up with a system of costly fines. Last week one of those hardened transgressors, the electrical companies, was convicted of a nuisance, under the Smoke Prevention Act, and sentenced to pay the substantial sum of £45. After that experience the County of London and Brush Provincial Electric Lighting Company will probably decide to adopt one of the excellent smoke reven-

tion contrivances now on the market. There is no need for a factory chimney to smoke.

Post-Prandial Frivolity.

At the Colchester Oyster Feast Sir Claude de Crespigny is reported to have made some extraordinary remarks concerning the unfortunate General Symons, to the effect that, "unless the general was killed by the army doctors there was every hope of his recovery." Not unnaturally this ill-timed and foolish remark has been sharply criticised, and while we do not suppose that the post-prandial orator intended any reflection on the Army Medical Service, he cannot but see that his reputation as a gentleman of sense and good taste must inevitably suffer, especially in view of the sad termination.

The Isolation of Infective Disease in Dublin.

PROGRESS has been made towards securing temporary provision for infective disease in Dublin, and establishing a *modus vivendi* between the Corporation, which desires to possess a special fever hospital under civic administration, and the authorities of the existing hospitals who fear that their institutions will be left out in the cold if this is done. Cork Street Fever Hospital has offered to expend £2,000 on enlargements if the Corporation will undertake to pay 2s. 6d. per head per day for all patients more than 40 admitted on the order of the Corporation, and Sir Charles Cameron, speaking for the Public Health Committee, has accepted the proposal, but strictly as a temporary measure, and without prejudice to the ultimate building of a sufficiently large special hospital. On the question of expense he stated that, in his opinion, a commodious hospital could be erected for £25,000, and he pointed out that the ratepayer would be amply recouped for such outlay, inasmuch as the existing slip-slop system of capitation subsidies costs him over £4,500 a year. While we welcome any temporary scheme for enlarging the available accommodation for infective cases, we certainly hope that such an expedient will not interfere with a permanent and sufficient settlement of the difficulty.

The O'Grady Memorial.

THE public memorial to the late surgeon Edward Stamer O'Grady, of Mercer's Hospital, Dublin, has been erected in Leinster Lawn, the garden in front of the Royal Dublin Society. It takes the form of a drinking fountain, the bowl being of marble mounted upon a base of Caen stone and raised by a granite foundation. When completed it will be an enduring and well-deserved testimonial to the public appreciation of his sterling qualities and surgical attainments.

New Method of Disinfecting Rooms.

THE report of the Public Health Department at Chicago informs us that an efficient and ready method of disinfection of hospital wards and other rooms is adopted in that city. The room having been prepared as for sulphur disinfection, and all contained articles exposed as freely as possible, a sheet, for every 1,000 cubic feet of space, is hung on

a line, and the operator rapidly sprays each sheet with a 40 per cent. solution of Formaldehyde, the room being then locked up for five hours. The operator must not lose time, as, after three minutes, the air becomes irrespirable.

A Cyclist's Death from Tetanus.

AN inquest was held in London last week on the body of a young lady, the daughter of a medical man, who had succumbed to tetanus following a bicycle accident. The case is of interest in view of the fact that immediate thorough cleansing of the wound did not prevent infection, and, when the disease had declared itself, repeated injections of anti-tetanus serum failed to check the course thereof. This is by no means the first case during the present year of death from tetanus as the result of cycling injuries.

A SILLY paragraph has been going the round of the Press to the effect that a Judge of the Supreme Court, of Connecticut, having stated that for a physician to shorten the life of a person afflicted with an admittedly incurable disease was not a criminal offence, a certain doctor, who shall be nameless, has made it publicly known that he is willing to act on this *obiter dictum*. It is hardly necessary to point out that such an act would be deliberate murder, punishable as such in every country in the world. We are all afflicted with an incurable disease—life, to wit—and the mere question of the mean prospect of life does not affect the principle involved.

MR. J. T. ARLIDGE, editor of the defunct *British and Foreign Medico-chir. Review* and several treatises on lunacy and hygiene, died at his residence, at Newcastle-under-Lyne, on Friday last. The deceased was a J.P. for Staffordshire, and while medical inspector of factories in the potteries was the first person to draw attention to the evils in the lead processes, and the agitation which followed resulted in the framing of special rules by the Home Office.

THE annual collection for the Dublin hospitals will be made on Sunday, November 12th.

PERSONAL.

DR. DUNCAN BURGESS has been elected President of the Sheffield Medico-Chirurgical Society, which held its opening meeting of the session on Oct. 19th.

SIR WILLIAM McCORMAC has volunteered to go to South Africa to assist in the organisation of the Army Medical Service, and his offer has been gratefully accepted by the Government. He is to be accompanied by two civil surgeons whose names have not yet been made public. Sir William will be attached to the headquarters staff as consulting surgeon.

DR. J. IVOR MURRAY, of Scarborough, has been elected President of the Balneological and Climatological Society, and took the chair at the meeting held on Thursday last. At the same meeting a vote of sympathy with Dr. Hyde (Chairman of Council) in his serious illness was proposed by Dr. Fortescue Fox, seconded by Dr. Symes Thompson, and passed unanimously.

THE Marquess of Dufferin and the Right Hon. Mr. Asquith, Q.C., M.P., have been nominated for the Lord Rectorship of Edinburgh University. The election takes place on Saturday next.

THE Earl of Rosebery was elected Lord Rector of Glasgow University on Saturday last by a large majority over Lord Kelvin. Our Glasgow correspondent informs us that the students carried "horseplay" to such an excess that it was thought probable at one time the Principal would declare the election null and void.

COL. G. J. H. EVATT, M.D., Principal Medical Officer at Hong Kong, has been ordered home at once to succeed Surgeon-General W. D. Wilson as Principal Medical Officer to the Western District at Devonport. The Colonel, who joined the Royal Army Medical Corps, in 1865, has had his full share of fighting. His war record includes the Perak expedition of 1876, the Afghan war, the expedition to the Soudan in 1885, and the Zhoob Valley expedition of 1890. He has on several occasions received the distinction of despatch mention.

The following staff surgeons have received appointment on the active list in the fleet:—Percy E. Maitland, to the St. George, on commissioning; Charles Strickland, to the Juno, on commissioning; John W. Slaughter, to the Cambrian, on commissioning; William W. Pryn, to the Minerva, on commissioning (all to date October 31st). Surgeons not on the staff:—William J. Codrington, to the St. George, on commissioning; William H. Pope, to the Juno, on commissioning; John W. Bird, to the Minerva, on commissioning; Arthur W. B. Livesay, to the Thunderer; Edwyn R. Grazebrook, to the Impregnable (all to date October 31st).

Correspondence

We do not hold ourselves responsible for the opinions of our correspondents.

Re I. M. S. AND THE R. A. M. C.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your admirable paper in the issue of August 30th, p. 219, under the heading "Enteric Fever in the Indian Army," makes a mistake, perhaps not unnatural, in attributing to the "Indian Medical Service" the blame for the prevalence of enteric fever in Indian cantonments. The Indian Medical Service has practically nothing to do with cantonments sanitation beyond the fact that the Director-General of the I.M.S. is the civil sanitary adviser of Government. The sanitation of military cantonments where alone enteric prevails, is entirely in the hands of military medical men, and chiefly the R. A. M. Corps. The spirit of militarism which you rightly inveigh against hardly, if at all, exists in the I.M.S. in spite of the titles recently thrust upon us. Moreover, the cause of the prevalence of enteric is by no means the easy matter it seems, and the water-borne theory by no means explains all outbreaks (e.g., the recent Quetta outbreak), but this is too big a subject to enter upon here. Much has been done, and much is being done; but difficulties are greater than appear to critics at home. Please distinguish between the I.M.S.—two-thirds of whom are in Civil employ, and which, in Prof. Ogsten's words, "still attracts the best graduates of the medical schools"—and the R.A.M.C. in India. As a rule we are, and have been for long, content, and have comparatively little sympathy with recent agitation, and as practical surgeons and physicians (civil) are by no means behind the times, as anyone who has visited the large medical schools, &c., in India can testify. We invite critics to come and

judge for themselves and see the work done by Indian medical officers in civil employ—see our hospitals, our gaols, our medical schools. The "intellectual sterility," the military soul-deadening system of seniority, does not exist for the civil surgeon, who is usually the sole European medical man, in charge of a district as large as Tyrone or Donegal, who is physician, surgeon, consultant, coroner, jail governor, first medical officer, meteorological observer, superintendent of vaccination, general practitioner, and specialist of his district! It is because of these responsibilities and the early independence that the I.M.S. still attracts the best men of the house—surgeon class to enter it. Please do not follow the *British Medical Journal* in confusing the I.M.S. with the R.A.M.C. serving in India. I am, Sir, yours truly,

T. C. D.

The Royal University of Ireland.

THE ceremonial of capping the new graduates of the University took place last Friday, and presented no feature of unusual interest. The Marquess of Dufferin, who as Chancellor of the University occupied the chair, in the course of his address referred to the great loss which the University had sustained by the recent death of Sir Christopher Redington, his Vice-Chancellor.

The degree of L.L.D. Hon. Caus. was conferred on the Right Hon. W. J. Pirrie, in consideration of his valuable services to the industrial sciences. Mr. Pirrie is one of the predominant partners in the great shipbuilding firm of Harland and Wolff, of Belfast.

Westminster Hospital Medical School.

At the meeting of the School of Medicine Committee on October 18th, the following prizes and entrance scholarships were awarded:—Epsom Scholarship, 110 guineas, to Mr. E. H. Bennett Bailey; Arts Scholarship, £40, to Mr. L. White; Oxford and Cambridge Scholarship, £40, to Mr. W. C. Hocken; Arts Scholarship, £30, to Mr. W. H. France; "Fish" Prize, £20, to Mr. W. Payne; Midwifery Prize, to Mr. W. Payne; Materia Medica Prize, to Mr. E. R. Carling; Forensic Medicine Prize, to Mr. W. Payne; Practical Chemistry Prize, to Messrs. T. B. Hickley and C. Parker; and Physics Prize, to Mr. O. P. N. Pearn.

Sheffield Medico Chirurgical Society.

THE session 1899-1900 was opened on October 19th. The following are the officers for the present session:—President, Dr. Duncan Burgess; Vice Presidents, Dr. Young, Dr. Kay; members to complete council, Mr. Leach, Mr. Reckless, Dr. Porter, Dr. White, Dr. Brown, Mr. H. Lockwood, Dr. McKay, Dr. Thomson (Retford), Mr. Shea (Chesterfield), Dr. Alfred Robinson (Rotherham); treasurer, Mr. Snell; librarian, Dr. Addison; secretary, Dr. Cocking. The President, Dr. Burgess, delivered the inaugural address on "Some Recollections of Medical Cases."

Death under Chloroform.

A MAN died at the Southport Infirmary on the 23rd inst., while undergoing an operation for the relief of intestinal obstruction, and the usual verdict was returned. The value of these records is stultified by the lack of details concerning the method of administration and the amount of the drug inhaled.

Small-Pox at Hull.

THE epidemic of smallpox at Hull has assumed disquieting proportions, upwards of 300 cases having, so far, been admitted to hospital. The problem of providing accommodation for this large number has taxed the resources of the authorities who are now actively engaged in adding to the beds available. Steps have been taken to induce people to be revaccinated, so far with a fair measure of success.

Suicide of a Medical Man.

AN inquest was held at Llandudno, on the 26th inst., on the body of Lancelot B. Todel, a medical practitioner, who had died from the effects of a self-administered dose of carbolic acid. The deceased had shown mental symptoms of a disquieting nature, but unfortunately it had not been thought necessary to place him under restraint. A verdict of "Suicide while temporarily insane" was returned.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

M.D.—The Cavendish Lodge (No. 2,620) founded by the staff of the West London Hospital, in connection with the West London Medico-Chirurgical Society. The secretary is Dr. P. S. Abraham, 2, Henrietta Street, Cavendish Square, W.

THE *Public Health Journal* is responsible for the following poetical outburst:—

THE PATIENT PATIENT!

They sawed off his arms and his legs,
They took out his jugular vein,
They put fancy frills on his lungs,
And they deftly extracted his brain.
'Twas a triumph of surgical skill,
Such as never was heard of till then;
'Twas the subject of lectures before
Conventions of medical men.
The news of this wonderful thing
Was heralded far and wide,
But as for the patient there's nothing to say,
Excepting, of course, that he died.

WESTERN COUNTY.—Our correspondent's memory has failed him. The facts first appeared in this journal in the issue of October 4th, 1899.

A NEW METHOD OF CONVERTING CENTIGRADE INTO FAHRENHEIT.

DR. WHITON, of New York, has brought forward a novel method of converting centigrade scale into Fahrenheit, which he claims is much simpler and easier to perform as a mental process. To convert F into C he subtracts 32 and adds one-ninth of the remainder, dividing the total by two. Thus 104 degs. F. — 32 = 72. Add to this 8 (the ninth of 72) and we have 80. Divide by two and we have 40, which is the corresponding figure in the centigrade scale.

BICYCLE SADDLES.

In the course of some remarks by "a leading cyclist," published in the *New York Sanitary Record*, on bicycle saddles, the writer condemns the ordinary makes on the ground that they bruise his *sternum bone*. This is after all a pardonable error in a layman, and even to medical students it seems anomalous to put the stern in front.

MEDICAL OFFICER OF HEALTH.—The Jenner Society (Honorary Secretary, Dr. Francis Bond, Gloucester), issues a mass of useful literature upon the subject of vaccination, to which society our correspondent should make application.

BEE STINGS.

It is stated by *Nature* that a solution of cocaine is a perfect cure for the stings of bees and wasps, being not only an analgesic, but an antidote.

DR. CLEMENT B. SEES.—We are unable to find space for a discussion on the grounds for belief in baptism and vaccination respectively, for reasons which are obvious.

DR. JOHN HATWARD.—Samples of the new fish food were obtained of W. R. and W. Smith, 6, Hanover Street, Glasgow.

THE PATENT MEDICINE TRADE.

ACCORDING to the most recent return the trade in patent medicines is spreading. The number of licences to sell in Great Britain (excluding Ireland) was, in 1897, 32,473; and in 1898, 33,992. Again, the revenue from the sale of patent medicine stamps was last year £265,404, the highest figure ever reached. In ten years last past the Chancellor of the Exchequer has received nearly two millions and a half from this source of taxation.

Meetings of the Societies and Lectures.

WEDNESDAY, NOVEMBER 1ST.

OBSTETRICAL SOCIETY OF LONDON.—8 p.m. Specimens will be shown by Dr. W. Duncan and others. Papers:—Dr. Herman: Two Cases in which life appeared to have been saved by Anti-streptococcal Serum. Dr. P. D. Turner: Notes on Tuberculosis of the Fallopian Tubes and Uterus in Cases of Phthisis.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square).—4.30 p.m. Dr. M. Dockrell: Lichen.

THURSDAY, NOVEMBER 2ND.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road).—8.30 p.m. Dr. J. W. Washbourn: Cases illustrating the Value of Treatment with Anti-streptococcal Serum.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 p.m. Dr. W. A. Foxwell: On the Causation of Functional Heart Murmurs. (Bradshaw Lecture.)

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—5 p.m. Dr. Dundas Grant: Differential Diagnosis of Nasal Discharges.

FRIDAY, NOVEMBER 3RD.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich). 8.45 p.m. Paper:—Dr. A. P. Luff: Modern Views as to the Causation and Treatment of Gout.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—Papers: Mr. J. G. Pardoe: Some Modern Methods in the Treatment of Chronic

Urethritis. Mr. S. Edwards: Urinary Obstruction with Cases. Mr. McAdam Eccles will show an Enema Apparatus from Central Africa.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover Square, W.).—5 p.m. Cases and Specimens will be shown by Dr. F. Poller, Dr. H. Mackenzie, Dr. St. Clair Thompson, Dr. D. Grant, Dr. W. Hill, Dr. H. Tilley, Dr. S. Spicer, and Mr. R. Lake.

SOCIETY OF ANÆSTHETISTS (20, Hanover Square, W.).—8.30 p.m. Dr. Savage: The Relationship between the Use of Anæsthetics and Insanity.

Vacancies.

County Borough of Great Yarmouth.—Medical Officer of Health, Medical Officer for the Yarmouth Isolation Hospital, and Port Medical Officer of Health. Salary £400 a year. Apply to the Town Clerk, Town Hall, Great Yarmouth.

County of London, Manor Asylum, Horton, Epsom.—Dispenser. Salary commencing at £110 per annum, with dinner daily. Cumberland.—Qualified Indoor Assistant. Salary £100. Apply, "Cumberland," MEDICAL PRESS Office, Dublin. (See Advert.). Apply to the Clerk to the Asylums Committee, Office, 6, Waterloo Place, S.W.

Glamorgan County Council and Cardiff Corporation.—Bacteriologist to the Joint Committee, and Lecturer on Bacteriology in the University of Cardiff. Salary, £300 a year. Apply to the Clerk, Glamorgan County Offices, Cardiff.

Hospital for the Insane, the Coppice, Nottingham.—Assistant Medical Officer, unmarried. Salary £150 per annum, with apartments, board, attendance, and washing.

Metropolitan Asylums Board.—Four appointments as Assistant Medical Officers at the Fever Hospitals. Salary £160, rising to £300, with board, lodging, washing, &c. Immediate applications to the Clerk to the Board. (See Advert.).

Royal Infirmary, Hull.—House Surgeon for two years, unmarried. Salary, 100 guineas per annum, with board and furnished apartments.

Stoke-upon-Trent Union.—Resident Medical Officer for the Workhouse. Salary commencing at £130, with board, washing, and furnished apartments. The Guardians provide the drugs, medicines, and appliances.—Applications to the Clerk, Union Offices, Stoke-upon-Trent.

Appointments.

HARRIS, WILFRED J., M.D.Cantab., M.R.C.P., Assistant Physician to the City of London Hospital for Diseases of the Chest.

KEY, DAVID T., M.R.C.S., L.S.A., Medical Officer for the Wyke Regis District of the Weymouth Union.

MARTIN, E. W., M.B., Ch.B., Junior House Physician to the City of London Hospital for Diseases of the Chest.

MOORE, E. J. F., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Workhouse, Bethnal Green, London.

O'FARRELL, H., L.R.C.P., L.R.C.S., Medical and Sanitary Officer for the No. 1 Portumna Dispensary District, Co. Galway.

PARSONS, C. T., M.D.Lond., Resident Medical Superintendent for the Fulham Union Infirmary.

POTTS, W. J., M.D.Lond., L.R.C.P., M.R.C.S., Medical Superintendent for the Infirmary, Bethnal Green, London.

PRICE, F. W., M.B., C.M.Edin., Assistant Resident Medical Officer to the Brompton Hospital for Consumption.

REED, WALTER HUGO, M.R.C.S., L.S.A., Medical Officer of Health by the Westbury (Wiltshire) Urban Council.

RORIE, G. A., M.B., Ch.B.Ed., Junior Assistant Medical Officer to the Cumberland and Westmorland Asylum, Carlisle.

ROWLANDS, WILLIAM CORBEN, M.B.C.M.Edin., Medical Officer at the Llynvi Colliery, South Wales.

STEVENS, BERTRAM, M.B., B.S.Durh., M.R.C.S., L.S.A., Senior Assistant House Surgeon to the Huddersfield Infirmary.

TAYLOR, HENRY YOUNG, M.B., C.M.Edin., Senior House Surgeon to the Huddersfield Infirmary.

THORNE, MAY, M.D.Bruce, has been appointed Teacher of Vaccination, and empowered to grant certificates by the Local Government Board. The Vaccination Station is at the New Hospital for Women, 144, Euston Road, London, N.W.

WILLIAMSON, O. K., M.A., M.B., B.C.Cantab., M.R.C.S., Pathologist to the City of London Hospital for Diseases of the Chest.

Births.

NEWTON.—On October 24th, at Balcombe, Sussex, the wife of Reginald Newton, M.R.C.S. and L.R.C.P., of a daughter.

Deaths.

ARLIDGE.—On October 27th, at Newcastle-under-Lyme, John I. Arlidge, M.D., F.R.C.P.Lond., J.P., age 77.

HOOLE.—On October 19th, Stephen Hoole, L.D.S.Eng., of 16, Old Burlington Street, London, W., in his 68th year.

LEWIS.—On October 26th, of scarlet fever, Frederick Henry Lewis, B.A., M.B.Cantab., M.R.C.S.Eng., and L.R.C.P.Lond., son of the late Dr. Frederick Lewis, of Gloucester Place, W., aged 32.

LIVY.—On October 24th, at Birkdale, Southport, John Livy, M.D., F.R.C.S., and J.P. of Bolton, aged 73.

PALMER.—On October 21st, at Lancaster House, Lincoln, Edwin Charles Palmer, M.A., M.B.Cantab., in his 35th year.

ROUTH.—On October 21st, after a short illness, Alfred Curtis Routh, M.R.C.S., of St. Leonards-on-Sea.

WOODWARD.—On October 17th, at Bellary, India, of enteric fever, Arthur Woodward, M.R.C.S., aged 26 years, only son of E. H. and T. J. Woodward, of 13, St. George's Terrace, Brighton.

No. 19.

Clinical Lecture

ON

LEPROSY AND CANCER OF THE SKIN.

DELIVERED AT THE LONDON HOSPITAL.

By JONATHAN HUTCHINSON, F.R.C.S., F.R.S.

GENTLEMEN,—Perhaps you may be somewhat surprised at my including leprosy in a lecture upon diseases of the skin, but I have deliberately done so because I wish to insist that in its earlier stages leprosy is purely a disease of the skin, and that all through the course the severest lesions are those which begin in the skin and extend to the tissues beneath it or to the superficial nerve trunks. Indeed, in the macular stage it presents many resemblances to lupus, occurring in symmetrical patches, spreading at its edges, and leaving in the centre instead of a thin pale scar, an anæsthetic area.

Not only is the disease in its earliest stages an affection of the skin, but it may remain so for years, and in mild cases terminate favourably without ever extending beyond this tissue. I have had under observation for some time an English leper, who has had the disease for at least ten years, and the only lesions he presents are numerous, patches of dusky erythema from the size of a half-crown to that of the outspread hand, with pale central area of total anæsthesia. These are scattered all over his trunk and limbs, especially well-marked upon the back and buttocks, and he made his own diagnosis for me by volunteering the statement that the skin "in the centre of them was quite dead." His general health is perfect, he is actively engaged in business, and absolutely the only inconvenience the disease has caused him in ten years' time is the patchy pigmentation of the skin for which alone he consulted me. He has not the slightest suspicion of the true nature of his malady, nor shall he have if I can help it.

Next in the normal course of the disease comes the development of cutaneous tubercles, sometimes firm circumscribed bossy elevations not unlike a large urticarial wheal, but more often only a thickening and œdema of normal folds of the skin, most commonly those of the brow and forehead. The old division of leprosy into the *anæsthetic* and *tuberculous* forms, was entirely uncalled for, they are simply stages in, and of, the same disease, and although the anæsthetic stage may exist for a long time without the development of the tuberculous, wherever tubercles are you invariably find well-marked anæsthesia also, and usually thickening of the ulnar nerve, and careful questioning will generally elicit a history of anæsthesia in some region of the skin, which began months or years before. Usually by some apparently accidental burn, as in a boy patient of mine who had a severe burn-scar across two fingers, due, as he explained, to his thrusting his hand into the flame of a candle by

his bed side, while yawning and stretching just after getting up one dark morning.

The relation between leprosy and tuberculosis we do not as yet clearly understand, but it seems unquestionable that one exists. The bacilli found in the lesions of the two diseases are strikingly similar, but their identity cannot be proved an account of the impossibility, so far, of cultivating the lepra bacilli upon any artificial medium. Dr. Geo. Newman informs me that the bacilli of leprosy are extremely similar to those of avian tuberculosis, both in their shape, in the clumps or masses in which they are found in the tissues, and in the small amount of reaction to or encapsulation of them by the fixed cells. It is also significant that the actual cause of death in the great majority of lepers is pulmonary tuberculosis. As to the cause of the localisation of the bacilli in the skin we are quite in the dark. It certainly is not due to direct local infection, but the virus must be distributed by means of the circulation, and probably to some degree under the influence of the nervous system, as the lesions are usually symmetrical.

One of the obstacles to the solution of the problem is the great difficulty in identifying the bacilli in the patches of the macular stage. But this, of course, is no more than we find in lupus erythematosus, which though regarded on that account by many as non-tuberculous, always occurs in members of families having a strong tuberculous history.

As for the fear of contagion in leprosy, I regard it as utterly unfounded. We have abundant evidence to prove that those living in daily and hourly contact with leprosy members of their own families, contract the disease only in the rarest of instances.

The spread of leprosy by direct personal contagion is a contingency which must be counted as merely a remotely possible accident. Cases occurring in the same household or village are much more probably due to identical food and surroundings than to any form of direct infection. Isolation is cruel, a fearful waste of labour, and leaves the real cause of the disease entirely untouched. It has never checked or limited the spread of the disease in the slightest degree.

As to the port of entry of the disease into the system it probably lies between the lungs and the alimentary canal. To my mind the balance of probability is strongly in favour of the food being the source of infection. In this it is again parallel with tuberculosis. The food theory of its causation I have elaborated so fully elsewhere that it is not necessary for me to enter into it in detail here. Suffice it to say that leprosy is *not* a disease of civilisation, but just the reverse. It is extremely ancient, and it may be said that there are few savage tribes living near large bodies of water in which it has not been prevalent at some time. The disease is singularly identical in all countries and races, and this uniformity argues a uniformity of cause. In all countries and continents it forms a ring round the sea-board, never

penetrating more than a few days' journey into the interior. It is not the richer and more varied diet which accompanies civilisation which has caused its disappearance but the withdrawal of one injurious food substance, badly cured or partially decayed fish. Wherever the use of this as an article of diet occurs, leprosy is present; wherever it ceases to be used leprosy disappears. In all probability the bacillus was conveyed, and found its intermediate home in the tissues of decaying fish, and was modified in some way by the "culture medium."

There is an especial appropriateness in taking up cancer as it appears upon the skin, as this is by far the best situation in which to study it. Here the very earliest stages can be detected, and every change which the process undergoes carefully noted.

An admirable illustration of this is found in epithelioma of the lip or "pipe cancer." Here the lip hardens and cracks under the pressure of the dirty pipe, the sore becomes warty at its edges, a cauliflower-like surface is developed, the glands under the jaw rapidly become involved, and fatal systemic infection is complete. In this form there have been two years of precancerous stage, and one of "frank" cancer, before the drama closes.

In striking contrast with this look at cancer (flat-celled) of the eye-lid or cheek, which may run for twenty or thirty years, and destroy almost the entire face without involving a single gland, or threatening the life of the victim. This is not a matter of region solely, because we may also have upon the cheek the "crateriform ulcer," which, though rare, is rapidly fatal.

In other cases of skin cancer, the disease may make its appearance in freckles, which, after childhood, are often to be regarded as abnormal. Their presence also often coincides with a tuberculous tendency. In the curious "Kaposi's disease" or xeroderma pigmentosum, we have dark and profuse freckles as the starting point of a disturbance which ultimately ends in cancer, hence its popular name "malignant freckle."

An abnormal deposition of pigment is always to be regarded with suspicion. Moles are frequently the starting point of malignant disease, usually sarcoma, especially those which are not congenital. Curiously enough, they may be the initial point of a general metastasis and yet be very little affected themselves. I have seen several cases of sarcomatosis of the entire skin, which proved rapidly fatal starting from a mole, which was so little altered that only by careful questioning could I elicit that it was the first spot to become swollen or slightly sore.

The character of the skin in which cancer originates has a marked influence upon its character. Rodent ulcer, for instance, is extremely mild and superficial upon the temple, but much deeper and more rapid upon the eye-lid or the ala of the nose. Xeroderma pigmentosum is a freckle cancer in the young and in the "second childhood" of senility we find again a tendency to develop freckles in which malignant disease has its origin. The black patches which grow around the eyelid in old women are specially liable to degenerative changes of this description. Cancer is emphatically a process of senile tissues, and while a parasitic origin may some day be demonstrated yet all attempts so far are conspicuous failures, and I personally cannot believe that there is any probability whatever of such a causation being discovered. The process is a disturbance of cell-nutrition, of internal balance, quite independent of any external cause. It is, in the nature of it, a self-originating process in the senile period.

Inheritance, though not a very common factor in cancer, is unquestionably a potent one. Many of the cases of cancer at an unusually early age that I have seen have been in the children of cancerous parents. I have under observation a case of rodent ulcer of the cheek in a boy of fourteen, whose father had

rodent ulcer for thirty years, and suffered from it at the time the boy was conceived. The disease does not necessarily attack the same organ when transmitted, more frequently not. What is inherited is the tissue-tendency to rebel, and this may take place in any organ or in connection instead of epithelial tissues, giving rise to sarcoma instead of carcinoma. I think the term cancer should cover both of these processes, the principle is the same in both, a rebellion of the cells; the particular tissue attacked is a detail.

As to the increase of cancer, of which we hear so much, I think it is greatly over-stated. According to some vital returns, in certain districts, it would appear to have increased nearly 500 per cent. in the past fifty years. I have a serious distrust of all registrars' reports and statistics as a basis for scientific deductions as to the frequency of disease. There are too many changes in nomenclature, in disease-classification, too many loop-holes and opportunities for mistakes both of diagnosis and of record in our methods of reporting deaths, to furnish any really secure basis. I think there can be little question that cancer is actually increasing slowly, but steadily. Simply for the reason that the proportion of those surviving to middle age, and those becoming liable to it, is increasing. Paradoxical as it may sound, cancer is a symptom of improving health on the part of the community.

Its distribution in the lower animals supports this position. It is comparatively common in dogs, cats, and horses, who are permitted to live to be old, while in cattle, sheep, and pigs, most of whom are killed for food before maturity, it is extremely rare. Another contributory cause of its increase is that marriages occur later in life than was formerly customary, and I believe, from my own experience, that the children of middle-aged or senile parents are more liable to cancer.

FOREIGN BODY IN THE FEMALE BLADDER.

By J. LAMOND LACKIE, M.D., F.R.C.P.E.,
Gynaecological Tutor, Royal Infirmary, Edinburgh.

MANY cases of foreign body in the female bladder are recorded, and in every text-book reference is made to the subject, but the accidental introduction of a large tortoiseshell hairpin, as represented in the diagram, is, I think, sufficiently rare to justify my recording the following case.

On July 24th of this year I was asked by her medical attendant to see a lady, æt. 25, who gave the history that that morning at 5 a.m., on waking from sleep, she felt a sensation of great itching in the region of the vulva. She therefore withdrew from her hair a tortoiseshell hairpin, and with the rounded end endeavoured to relieve her discomfort. Presently, however, the hairpin slipped from her fingers and disappeared, and to her surprise she found she could not regain it. Later in the day she informed her mother of the accident and began to have frequent and painful micturition. The lady's doctor was sent for, and, as on examination he could not detect any foreign body in the vagina, he concluded that it had passed into the bladder.

The patient being anæsthetised, the bladder was explored by means of a sound, when I easily detected the presence of a foreign body. The urethra

was therefore dilated by means of Hegar's bougies and the index finger of the left hand introduced until it came in contact with the two sharp points of a hair-pin of the nature described by the patient. An effort was first of all made to pass a pair of forceps alongside of the finger, and to approximate these ends and so withdraw the pin, but this proved impossible. I therefore determined to turn the foreign body so as to get the rounded end next the urethral canal. This I accomplished only with great difficulty, since when the pin came to be lying transversely, the sharp ends persisted in penetrating the membrane, and remaining fixed. Ultimately, but only after persevering for half an hour my object was attained, and then, on passing along a pair of very finely-bladed forceps the pin was grasped and easily withdrawn. There was considerable hæmorrhage from rupture of the external meatus, and one feared that owing to the considerable stretching of the urethra the patient might suffer from incontinence of urine for some time, but, fortunately this was not the case, as she never lost control of the function of micturition, and twenty-four hours later seemed perfectly well.

It is surprising to what an extent the female urethra may be dilated without any permanent harm. Although at one time the operation was frequently resorted to for purposes of diagnosis, of late years it has fallen into disuse, to a large extent owing to the introduction of improved methods of cystoscopy. Howard Kelly has especially condemned the dilatation of the urethra and the introduction of the finger as a means of diagnosis, and has devised a method of examining the bladder by direct illumination, which obviates much stretching of the urethral canal. However, in a case such as I now record it seems to me that the plan adopted was preferable to the alternative of anterior colpotomy and the removal of the foreign body per vaginam. In most cases, even after greater dilatation than that resorted to in this case, permanent incontinence of urine does not result, the patient regaining control of the bladder, if not at once, at most in the course of a few days. Further, the operation of colpotomy must always entail a certain risk of vesico-vaginal fistula.

RELATIVE WORTH OF ANTISEPTIC AND TECHNICAL IMPROVEMENTS FOR THE ACTUAL RESULTS OF OPERATIVE GYNÆCOLOGY. (a)

By PROFESSOR E. BUMM, M.D.,
Of Basel.

THE absolute reliance on the protective power of antiseptics has been a good deal diminished by exact investigations, as it has been proved by a whole series of experiments and observations that elimination of all micro-organisms during the operation, has not yet been attained. We can sterilise the instruments and dressings, but no method has been discovered, at least up till now, that gives us with certainty the same result as to the skin of the hands and the part to be operated on.

A year's bacteriological research made during a great number of operations from beginning to end upon the skin of the hands as well as the operation field, the wound, the instruments, the dressing and ligature material, have given me the following results:—

(a) Abstract of paper read before Congress of Gynecologists, Amsterdam, August, 1899.

1. There is no way to remove with certainty all micro-organisms from the hands. The successive use of soap and hot water, of alcohol, and of a solution of lysol or sublimate, for ten minutes each, are not sufficient to ensure the sterilisation of the skin. For these experiments rigid precautions, as prescribed in Hägler's method, are necessary to obtain satisfactory results. Above all it is not sufficient to examine only a small part of the skin of the hands, to remove the adhering remainder of the sublimate, taking into account the shrivelling of the skin by the alcohol.

2. The same conclusion is to be drawn with regard to the skin of the rest of the body and especially for the external genitals, the perineum, the vagina, &c.

3. During the course of the operation we find on the instruments and ligatures and in the wound principally the micro-organisms originating in the deeper parts of the epidermis and from the glandular ducts. In fifty great operations, under exact control, none were found entirely free from the presence of micro-organisms.

4. With the "aseptic" method, even when the operation is made in the best conditions and with the greatest precautions, the number of micro-organisms is far higher than that which is found in using the antiseptic method. At the end of the operation the, so-called sterile, salt-solution contains regularly micro-organisms and sometimes in great number.

5. The micro-organisms of the atmospheric dust are but of small importance in the infection of operation wounds.

6. Difficult as it is to operate without giving access to the micro-organisms, it is still more so to keep them away from the wound and its surroundings for a longer amount of time. It is, therefore, illusory to think that either asepsis or antiseptics can bring about a sterile condition of the wounds. According to circumstances there will be in every wound more or less bacteria. In spite of this proved presence of micro-organisms most wounds heal without supuration or fever. This result is due to the bactericidal power of the organism. But this bactericidal power of the organism can be insufficient, and this occurs when the wound is brought into contact with virulent micro-organisms or when it presents bad conditions for the full development of the bactericidal qualities of the tissues and humours.

Formerly the access of virulent micro-organisms to the wounds was only a question of chance. Actually antiseptics gives us the means to avoid this contact. But, as virulent micro-organisms are generally found in the secretions of wounds and in the humours of the infected body, and as, on the other side, a true disinfection of the hand, impregnated by these infective secretions, is impossible, the dominating element of every asepsis or antiseptics should be the avoidance of the contact with septic matter, abstinence when the contact has taken place, and isolation of septic patients.

The second possibility of insufficiency of the bactericidal power of the organism brings us to a point where the territory of technique covers that of antiseptics. Technique has to remedy the insufficiency of our antiseptic and aseptic means, it has to arrange the conditions of the wound in such a way that the may organism be able to win the struggle against the never entirely missing bacteria.

In this view it can be said that purely technical means have a great influence on the aseptic healing of wounds.

I should like to give some examples to show this more clearly.

A short and well-conducted operation exposes the tissues only for a short time to the influence of exterior surroundings and brings manipulation to a minimum; in this way it diminishes the chances of

accidental infection. The number of micro-organisms entering the wound will be a good deal less than in an operation of long duration, in which the tissues are lacerated by repeated manipulations.

In addition to this a short operation does not so much tax the resisting power of the wounded tissues as well as of the entire organism. To expose the peritoneal cavity during a long time has a well known bad influence on the heart, the intestines and the serosa. Asepsis has delivered us of the dangerous application of too much concentrated disinfectants.

The importance of hæmostasis for the aseptic healing of wounds is universally recognised. The drier the wound, the better are the chances for primary healing. On the other hand the blood, as soon as it has left the vessels loses its bactericidal properties and becomes an excellent medium of culture for the micro-organisms. This being especially the case for the peritoneal cavity, for abdominal operations exact hæmostasis is at least as important as exact asepsis.

Next in importance comes the choice of the operative way. Neither the operation per vaginam or by laparotomy should be condemned by principle. In cases when per vaginam the part to be operated can be better exposed to view, so as to facilitate exact hæmostasis and avoid injuries of the surroundings, presenting as it does the least danger, it is therefore the best. But should it appear that the employment of this method prevents obtaining a good view, it would be better to overlook the difficulties belonging to asepsis and follow the directions of the technique demanded by laparotomy.

A last point, where antisepsis and technique meet is drainage, and especially drainage of the peritoneal cavity. It is an established fact that drainage, even on the greatest scale, has no effect whatever on diffuse septic peritonitis. But the case is quite different when we have local troubles to deal with, as circumscribed abscess, extensive lacerations of the serosa or contact of the serosa with infectious matter. In these conditions we ought not to expect more of the peritoneum than from any other wound, and I then apply drainage by gauze tampons, from which mode of treatment, I have never experienced other than favourable results, and would prefer applying it once too often than omitting it.

From all this the conclusion ought to be that to obtain an entirely satisfactory result, antisepsis and improved technics have to go hand in hand. The one without the other is not sufficient. The history of intraperitoneal treatment of the stump in myomectomy furnishes a good example of the importance of technique in relation to antisepsis.

Antisepsis is easily learned and executed. But technicalities are more difficult to learn; they represent an art, that demands above all things a born aptitude. It is high time for instruction in surgical technique, of late much neglected for antisepsis, to be reinstated in its place of honour.

NOTES ON

POISONING BY PRIMULA OBCONICA. (a)

By E. MACDOWEL COSGRAVE,
M.D., F.R.C.P.I.,

Professor of Biology, Royal College of Surgeons; Physician to Cork Street Fever Hospital.

THE following notes on poisoning by *primula obconica* were suggested by a case which lately came under my care. The patient, who came to see me on September 23rd, 1898, was a lady who was very

fond of gardening, and had in her greenhouse some fine young plants of *primula obconica* which she tended daily. For the previous seven weeks she had had irritable red patches on the wrists and forearms, with here and there the surface broken.

The eruption came out suddenly, appearing on the wrists and lower half of the forearms within twenty-four hours. In a few days it died away from the arms, and, as it died, came out at the back and sides of the ankles; in about a month the rash recurred on the wrists and arms, and had, when I saw her, remained out for about three weeks, although the plants were no longer being tended. The rash varied in appearance—sometimes it was urticarious, sometimes eczematous, and occasionally papules formed and passed on into pustules. There were attacks of intolerable itching, and sometimes of severe neuralgic pain; and all the time, whether the rash was visible or not, the patient had epigastric uneasiness and felt sick and out of sorts.

The progress was slow; bathing the affected regions with very hot water, and the application of dilute citrine ointment giving most relief.

On glancing over Neale's Digest and recent volumes of the medical journals, and such papers as *The Garden, Gardening*, and the *Gardeners' Chronicle* a number of references will be found to toxic symptoms following contact with *primula* plants.

Primula obconica was introduced into this country about 1880, and as it flowers freely all through the winter it has rapidly come into favour. It has loose umbels of pale lavender blossoms and slightly tapered leaves from whose shape it derives its specific name.

Other varieties of *primula* also have poisonous properties, especially *P. Sieboldii* (1), which under the name of *Cortusoides amena* was introduced into these countries about 1864.

As these cases occur among those handling plants the hands are more generally affected. In my case short gloves were worn when gardening, so the wrists were the seat of the disease. With gardeners the parts of the hand least well-protected by a thickened horny layer are generally affected. Thus, Dr. Allan Jamieson (2) describes a case where the ball of each thumb and the back and extending to the palmar surface of some of the fingers was the seat.

When other parts are affected it may be by contact, and they are then those parts which are most easily touched by the hands. Dr. Kingsley Ackland (3) records the case of a lady who had repeated attacks on her hands, and on one occasion had her chin affected.

In Dr. Clark's (4) case the eye-lids were affected from rubbing them to remove flies.

Dr. Oldacres (5) describes a case accompanied with much swelling of the face and much œdema of the eye-lids.

Dr. Wilson, (6) of St. Andrew's, mentions the case of a lady who suffered martyrdom with an irritable rash on her neck and chest. She was very fond of the *primula obconica*, and always wore its lavender flowers in the evening. When the favourite flower was given up the rash disappeared.

There may be extreme sensitiveness to the poison. A lady (7) at dinner complained of irritation of the face and nose and of the body generally; four pots of this *primula* were on the table, on their removal the irritation subsided. Next day the irritation recurred when the lady was in the conservatory, although she was not within six feet of the plant.

Sometimes, however, as in a case of which I have notes, the rash is general, and so its extension from the parts which touched the leaves is due not to external but internal causes.

The rash varies in appearance in accordance with the intensity of the attack. In its lightest form it is a simple dermatitis with a more or less abundant

(a) Read in the Medical Section, Royal Academy of Medicine, May 19th, 1899.

crop of small red papules. (11) Dr. Ackland (3) speaks of it as an intensely irritable papular eruption. Cases described by Dr. Oldacres (5) have been called by some eczema, and by others urticaria. Dr. Sym (1) describes the appearance as that of a moist eczema, papulous and excoriated.

Dr. Allan Jamieson (2) describes a severe case as having "well-defined, hard, red, scaly areas. The edge was distinctly raised and linear, the horny layer of the epidermis ragged and undermined. The general surface of the patches, which were of considerable extent, was rough to feel, thickened, and had a tendency to fissure."

The course of the disease can best be understood by comparing the descriptions of a light and a severe case. In the former, (3) in a little more than twelve hours after contact with the leaves, a broad band of small papules appeared on a raised base, and gave rise to almost intolerable itching.

In a severe case as described by Dr. Leighton (9) the patient was "suffering from tremendous oedema of the right hand, with well marked lymphagitis of right arm and tenderness in axillary glands. Next day there began a profuse serous discharge from between the second and third fingers. The pain in the joints was excessive, and the patient was slightly feverish. The discharge continued for eight days, gradually decreasing.

In addition to the itching, which is generally urgent, there is often severe neuralgic pain, and frequently, as also occurred in my case, there are dyspeptic symptoms. (5)

The duration of the rash is variously described. Dr. Clark's case (4) must have been mild, for desquamation ending in recovery took place in four or five days. In my case the skin trouble lasted several months, and in the case of a gardener, of which I have notes, it lasted a couple of years.

Tolerance is not easily established, as in a case published by Dr. Clark where some plants were brought indoors (their leaves being held aside daily whilst the roots were watered), the condition of the owner's hands became chronic. Several cases have been reported where handling the flowers after cure led to repeated attacks which showed no diminution in severity.

A troublesome symptom is the occurrence of relapses. My own case affords an example of this, and Dr. Leighton (9) reports a case with two relapses, the time between the first and second being eight months, and between the second and third sixteen months.

Dr. Pooley (10) reports a very interesting case:—"A market-gardener who used *primula obconica* in making funeral wreaths did so with impunity until he got an attack of facial erysipelas (his son, who did not touch the plants, had erysipelas at the same time, which confirms this part of the diagnosis), and got six relapses when working with the *primula*, the fingers also being affected." This susceptibility to *primula* poisoning following erysipelas is interesting.

The discovery of the cause of the attack is sometimes due to the patient being a reader of gardening papers. In a case reported by Dr. Oldacres (5) the discovery followed indirect experiment—An old lady who suffered repeatedly from a troublesome rash and always got relief by going away from home read a letter in the *Gardeners' Chronicle*, and suspecting that her troubles might arise from the same cause gave up handling the plants, and received the benefit that had previously followed the change of air.

Direct experiment was made by a lady whose case is reported by Dr. Ackland (3)—"She bared her arm and lightly pressed a bunch of its leaves round the middle of the forearm. Nothing happened until the next day, more than twelve hours after the experiment, when a broad band of small papules appeared

on a raised base, giving rise to almost intolerable itching."

Dr. Wilson, (6) of St. Andrew's, examined the plant and found glandular hairs on the leaves, which he suggested as the cause of the trouble. Greenwood Pim, F.L.S., has kindly examined the hairs for me and reports—"The hairs on the leaf-stalk, flower-stalk, and mid-rib are of two kinds—one long and rather slender with six or seven septa and a slightly glandular tip, apparently, not functionally glandular; the others short, about two to three septa with a distinctly glandular tip, containing a yellowish-brown material, doubtless the irritant. The hairs are delicately striated under a high power. Those on the lamina are few and rather conical, also with aborted glands."

It is probable that the young freely growing leaves have most effect, (11) and possibly some plants are more virulent than others, as generally when the disease occurs several people are affected.

Dr. Oldacres (5) records how a lady "by way of experiment has handled the plant a few times, which has always resulted in the return of the rash and the dyspeptic symptoms. Further, two of her nephews who have been staying with her have handled the plant to test its effect upon them, and have suffered from the rash in the same way." And a gardener (12) who tried to infect himself failed, although, subsequently, when engaged in potting plants, he got a severe attack.

DUSTING POWDERS IN DISEASES OF THE SKIN.

By DAVID WALSH, M.D. Edin.,
Physician, Western Skin Hospital, London, W.

THE treatment of diseases of the skin offers, as regards the application of remedies, certain advantages that do not as a rule present themselves in dealing with internal maladies. In other words, the dermatologist is able to apply his medicaments directly to the diseased surfaces, and to note results with accuracy and certainty. He finds lotions, ointments, wet or dry dressings, dusting powders, plasters, varnishes, pastes, liniments, and other approved methods ready to his hands. By these means he may direct his attack so as to secure short or prolonged contact of antiseptics, calmatives, stimulants, protectives, caustics, parasiticides, and the rest of his therapeutic weapons. The use of dusting powders dates from ancient times. Their function is two-fold, (1) Cosmetic, to dry up the physiological moisture or greasiness of the skin, as in the ordinary face powder; (2) Medicinal, to absorb discharges from inflamed surfaces, and also to medicate and protect the skin from contact with irritating material.

1. Cosmetics. Little need here be said under this heading. The practice of "powdering" the face was probably known to primeval woman, and dated from her first consciousness of the advantages of personal attraction. That the rubbing of powders into the

face is bad for the skin cannot be doubted. Sometimes irritant or poisonous substances, such as arsenic or lead are contained in the powder. Even when the ingredients are in themselves harmless, it follows from the nature of the application that the ducts of the skin will be more or less obstructed. Clearly, the finer the powder the more mischief is likely to ensue from the choking of sweat and sebaceous ducts.

The use of toilet powder in the nursery, however, is a good and sufficient excuse under the conditions that rule the rearing of children, whatever may be said of adult cosmetics. Its chief function is to absorb irritating discharges and keep the skin dry. For that purpose it is freely sprinkled over the buttocks and genitalia of babies, in whom the exigencies of civilised up-bringing have decreed that the evacuations shall be caught and confined in napkins. The irritant nature of that particular kind of infant swathing is shown by the frequency with which rashes are confined to what is aptly termed the "napkin area." As everyone knows who is versed in the skin affections of infantile syphilis, the development of a specific rash is most typical and common in that particular region of the body. Now and then there can be no doubt that the toilet powder sold by the chemist has contained an irritant drug, but the majority of cases are due to other causes. If good powders be used for normal and abnormal skins there will be little difficulty in vindicating the traditions of the nursery as to their value and necessity.

The best drying powders for babies are made of the simplest materials. Where the skin is healthy violet powder, starch, or fuller's earth, if pure, will answer the purpose. The addition of a little boracic acid or other mild antiseptic is desirable. It is hardly necessary to use the pure boracic acid that forms the bulk of some toilet powders. Where the surface of the skin is inflamed the nature of the powder should be modified. In cases of slight irritation the following formula is excellent:—

R Acid Boracic Pulv. ;
Calamine, aa ʒij ;
Amyli Pulv., ad ʒij ;

M. ft. pulv.

Where there is weeping or severe inflammation (especially if syphilitic) two drachms of Europhen may be added.

2. Medicinal.—Dusting powders are chiefly useful in all periods of life in the treatment (a) of inflamed folds of skin, or intertrigo, in groin, armpit, and so on; (b) of excoriated and weeping surfaces; (c) of open ulcers.

(a) These eczematous inflammations of opposed folds or areas of skin are often due to seborrhoea, or to parasitic fungi. They are common in the groin, armpits, bends of arms or legs, perineum, about the scrotum and buttocks, between the mammae, and creases of the skin of neck and belly in stout persons.

The writer has found the best powders for this condition are made of starch, with oxide of zinc, or calamine, and an antiseptic in the shape of boracic acid (ʒj or ʒij to the ounce), salicylic acid (grs. x. to the ounce) or Europhen (ʒss or ʒj to the ounce). The last-mentioned is an odourless substitute for iodoform. The addition of a little calomel is often useful.

(b) Excoriated surfaces, result from injury, or from an irritant which may attack the skin from without, or according to the writer's theory of excretory irritation, either from within (a). A true eczematous condition, that is, a catarrhal weeping inflammation of the skin without obvious cause, is probably an extremely rare condition. In any case the object of

the powder is to protect, to absorb discharge, and act as an astringent, to provide an antiseptic and aseptic application, and indirectly to form an artificial scab, and thus imitate the natural processes of healing.

Starch is one of the best drying applications to a moist inflammatory surface. Another excellent application is the compound powder of chalk. Slight astringency is obtained by adding zinc oxide or carbonate (calamine) and antiseptic action by boracic acid, salicylic acid or Europhen. Calomel is a good powder for unbroken skin, but is apt to do damage in a moist or discharging skin, possibly owing to the formation of a perchloride. Its use is strongly indicated, however, in syphilitic rashes about the buttocks of children. Kaolin (a silicate of alumina) is apt to irritate some skins, but can be used with a tar preparation. Iodoform, besides its unpleasant smell has the disadvantages of setting up an acute dermatitis in some persons who have a predisposition against the drug, and other vehicles of active agents are rice, arrowroot, orris root, lycopodium, and talc.

For a simple excoriated surface:—

Calaminae, ʒij ;
Europhen, ʒj ;
Amyli, ad. ʒj.

M. ft. pulv.

(c) Open ulcers, whether specific or non-specific, are often greatly benefited with dusting powders. Certain precautions are needed. Boracic and salicylic acids often cause great pain. Calomel is rarely safe to apply to any but the syphilitic sore, whether hard or soft. Iodoform is excellent for both ulcers, whether specific or non-specific. Europhen is somewhat less active as a substitute, but has not the offensive smell of iodoform. A plan used by the writer in treating non-specific ulcers is to incorporate a bland powder (e.g., starch and boracic acid), with a pad of absorbent boracic wool, applied as a dry dressing. The usual way of applying these external applications is to dust the material on with a swan's down pad or a pledget of cotton wool; or it may be peppered over the surface from a small dredger. One of the most satisfactory ways of procuring prolonged contact with the skin is by Unna's plan, by which the powder is sewn up in long flat bags, and bandaged to the skin.

The use of dusting powders is a point that will repay the attention of medical men engaged in practice. The foregoing brief sketch of their essential features will, it is hoped, prove of some practical service to the readers of this journal.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.

MEETING HELD WEDNESDAY, NOVEMBER 1ST, 1899.

MR. ALBAN DORAN, President, in the Chair.

TUBERCULOSIS OF THE FALLOPIAN TUBES AND UTERUS IN PHTHISIS.

DR. P. D. TURNER gave the results of the examination of the genital organs of twenty-seven consecutive cases of phthisis in female subjects at the Brompton Hospital. Tuberculous lesions of an undoubted character, the bacillus being present, were found in five cases = 18·5 per cent. In one the tubes alone were involved; in two the tubes and the body of the uterus; in one the tubes, body of uterus and cervix, and in one the tubes, body of uterus and ovary were affected. All five were cases of chronic phthisis, and all had intestinal ulceration. In seven of the remaining cases there was some evidence of interstitial or catarrhal sal-

(a) "Excretory Irritation." By D. Walsh, M.D. London: Baillière, Tindall, & Cox. 1897.

pingitis, the condition in several suggesting a tuberculous origin. No note had been taken of tuberculosis of the peritoneum merely covering the genital organs. The results, as far as they went, seemed to show that tuberculosis of the uterus was more common than supposed. He pointed out that the typical tuberculous tube was much thickened and distended, and showed an opaque yellowish-white surface with a swelling which increased from the uterus to the junction of the inner and middle thirds, the outer two-thirds being more or less cylindrical and the thickening ending abruptly at the fimbriated extremity. The extremity of the tube was often pervious showing the caseous contents which sometimes projected through it. The adherent extremity of the tube often formed part of the wall of an abscess cavity, more rarely there was hydrosalpinx as in a case where the tuberculosis appeared recent and acute. It was evident that the disease had advanced from the outer to the inner extremity of the tube. He described the earliest appearances adding that at a more advanced stage, giant cells with bacilli were found. Still later, the mucous membrane was replaced by tuberculous material, the muscular coat ultimately being invaded. At this stage, giant cells were still visible, but the bacilli rarely. In the ultimate stage, the tube was represented by a caseous mass covered only by peritoneum. He pointed out that the ovary did not offer the same nidus for infection, and hence was comparatively rarely diseased.

Mr. TARGETT mentioned that out of 2,500 autopsies in women during 12 years in St. Bartholomew's, in only 12 was tuberculous disease of the tubes noted, less than one per cent. In 450 there was old or recent disease of the lungs, and of these, 45 had tuberculous peritonitis, and 20, tuberculous disease of the tubes and ovaries.

The PRESIDENT suggested that the hydrosalpinx was a source of irritation which sealed the tube. Primary tuberculous disease of the tube was a very serious condition, in which the question of removal must be entertained.

Dr. TURNER, in reply, said that none of the patients presented any symptom referable to the uterus or tube. The dictum that tuberculosis anywhere in the body always showed itself in the lungs after puberty was falsified by one case, in which nothing was found in the lungs. In the early stage one met with bacilli and no giant cells, while later the giant cells developed and the bacilli disappeared.

TWO CASES IN WHICH LIFE APPEARS TO HAVE BEEN SAVED BY ANTISTREPTOCOCCIC SERUM.

Dr. G. ERNEST HERMAN began by remarking that judgment as to the therapeutic value of the antistreptococcic serum is difficult, because we know not yet enough about the effects of the streptococcus. If the antistreptococcic serum fails, it may be because it is used too late, or because the patient has been poisoned by some microbe other than the streptococcus. In some cases published as examples of success from the antistreptococcic serum, it has seemed to the author, from reading the reports, that some of the patients were never in danger, and that in some recovery was to be attributed to other therapeutic measures (such as removal of retained placenta) used at the same time as the serum. For these reasons it seems to the author impossible at present to draw conclusions as to the value of the serum from statistical tables. The author submitted two cases, in which, in his opinion, the symptoms were such as to warrant a very unfavourable prognosis, but nevertheless the patients got quite well after antistreptococcic serum. The first was a case in which a severe operation was followed by great prostration from which the patient recovered, but the rally was followed by renewed prostration, such as in the author's former experience had ended in death. With antistreptococcic serum the symptoms quickly improved, and the patient got well. The second was a puerperal case, in which the occurrence of three severe rigors on successive days led the author to think that the patient was suffering from pyæmia, and that secondary abscesses, &c., might be expected. With antistreptococcic serum the symptoms improved, and the only development was a small patch of cellulitis which ended in resolution. He admitted

the difficulty and uncertainty of prognosis in cases such as those now reported, but he submitted that, in the present state of our knowledge, it is only by the consideration of cases such as these that judgment can be formed.

Dr. CLAPHAM (Wimbledon) referred to a case delivered by a midwife, in which the patient presented symptoms of marked septicæmia. There was nothing in the uterus, but he washed it out with bichloride solution without any effect on the temperature, which, however, fell during the next day. High fever with rigors occurred on the fifth day, and he curetted. Still the temperature increased, so he gave 15 cc. of serum. The temperature fell to 102 degs., but rose again to 105 degs., and did so for five nights. The patient was desperately ill, but on the tenth day, after five injections, great improvement took place. A subsequent rise of temperature occurred, followed by effusion into the knee, and an abscess formed in the left labium. The blood was examined, but nothing of interest was found.

Dr. HORROCKS said that at first he thought he had got hold of an unfailing remedy, but subsequent experience had qualified this belief even when used at an early stage. He was afraid that the bad cases did not recover, and he mentioned several instances in support of this view. He thought, however, that in bad cases the serum afforded the only possible chance, and he hoped that in time it might be made more active.

Dr. A. ROUTH said that something ought always to be done besides giving the serum, therefore one could never be sure how much of the credit was due to the serum. He referred to the only case in which he had used it, in which immediate improvement had followed.

Dr. CULLINGWORTH said nothing was more difficult than to estimate therapeutical effects, and he related a case which was rapidly getting worse under ordinary treatment. A fortnight after admission the interior of the uterus was examined, but practically nothing was found to account for the condition. Then serum was given in 12 injections of 10 cc. in seven days, yet the temperature that day was 104.8 degs. F. He also referred to another case of a patient who had been curetted and some decomposing material removed, but she got worse instead of better, so serum was injected and the temperature immediately fell, although before the serum was used that patient was almost moribund. He urged that every case in which it was tried should be recorded.

Dr. EDEN observed that their treatment seemed to be outrunning their pathology. The streptococcal origin of puerperal fever was by no means proved; indeed, its etiology appeared to be very varied. He thought it was of prime importance in all these cases to demonstrate the presence or absence of the streptococcus. The author did not seem to attach much importance to bacteriological examination, but if the streptococcal origin were not proved, their treatment was empirical. Any future improvement in the mortality of puerperal fever might fairly be attributed to the new treatment.

Dr. CULLINGWORTH observed that the object of "prime importance" was to cure the patient.

Dr. EDEN retorted that the search for the bacterium need not prejudice the cure of the patient.

Dr. CULLINGWORTH said it would if they had to wait.

Dr. EDEN replied that it was not indispensable to await the result of the examination.

Dr. ROBINSON said that if they were going to wait until the bacteriology of puerperal fever had been worked out they might have to wait a long time. He referred to a case of his own in which, on the third day, the patient, who had been attended by a nurse, had a rigor and became very ill. He saw her on the eleventh day when she appeared to be dying. He mentioned incidentally that the whole of the vagina was covered by a thick whitish-yellow membrane, which contained streptococci. He advised serum treatment, and within a day or two the membrane melted away and the patient began to recover. With reference to the suggested bacteriological examination he asked how it was intended this should be made?

Dr. EDEN said by examining the uterine excretions and the blood.

Dr. POLLOCK suggested that the cases which recovered

were cases of pure infection, and those that did not recover of mixed infection.

Dr. MACLEAN insisted on the fact that practically the same disease was produced by a large variety of organisms, and the serum which rendered immune to one germ was perfectly tolerated by another so that the injection of antistreptococcal serum might be far from a help.

Dr. A. ROUTH recalled that on a previous occasion Dr. Cullingworth had stated that the serum was harmless even when it did no good.

Dr. HORROCKS said that if properly sterilised it was probably absolutely safe, and might even supply a little nourishment to the patient, and he mentioned that a dog had been kept alive by injections of serum for three months without loss of weight. It did not matter if the serum were a little coloured, but it should not be used if turbid.

Dr. SPENCER said he gathered that the general sense was in favour of continuing the use of the serum in cases of septicæmia. He doubted whether the streptococcus was as frequent as all the other organisms put together as a cause of septicæmia. It did not seem reasonable without knowing this to employ the serum. He stated that the injections were by no means free from danger, for there were cases in which death had occurred shortly after them. He had not been struck by the result in the author's cases, for he had seen similar cases recover without the serum, moreover, the injections were sometimes followed by a rise instead of a fall of temperature. In short, he looked upon it as an empirical treatment, the value of which was far from proved.

The PRESIDENT observed that however desirable such a remedy might be, he was afraid it could not yet be said that the serum was that remedy.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD WEDNESDAY, NOVEMBER 1ST, 1899.

Sir JOHN BATTY TUKE, President, in the Chair.

Dr. JAMES showed a patient, æt. 9, the subject of slight "cretinism." Her younger sister, æt. 7, was eight inches taller, and suffered from a cystic goitre.

Dr. JAMES also showed a rare skin affection—keratoderma symmetrica erythematosa.

Dr. GIBSON showed a case of slight "cretinism" with cystic goitre.

Dr. LOVELL GULLAND read a paper on

THE IMPORTANCE OF THE EXAMINATION OF THE BLOOD IN DOUBTFUL CASES OF DISEASE.

The author first emphasised the necessity of examining the blood in all doubtful cases, a procedure too much neglected in this country, though its value was fully recognised in America and Germany. The blood was the only tissue which could be examined during life, and this alone was enough to show the importance of not neglecting it. Cases of blood disorder, pernicious anæmia, leucocythæmia, and the like, did not come within the scope of the paper. In systematic examination of the blood we had to consider the number of the red corpuscles, and the percentage of hæmoglobin, the number of the blood plates, the rapidity and amount of fibrin formation, and most important of all, the number of leucocytes and the proportions of the different varieties. The enumeration of the red corpuscles was of less importance in general disease than in blood disorders. This was because alterations in them, secondary anæmia, were more or less the same in all diseases, depending entirely on the severity of the cause producing them. At the same time, the number of red corpuscles present in an acute or chronic illness had an important bearing on the prognosis. The number of the blood plates and the amount of fibrin were difficult to estimate, and, with one exception, were of little diagnostic value. But in cases where the diagnosis lay between malignant disease and suppuration—in both of which a leucocytosis was present—the amount of fibrin might be of value, as it was decreased in the former, and increased in the latter.

Far the most information, however, was got from the leucocytes. Indeed, for clinical work, a leucocyte count and the preparation of stained films were the essentials. The amount of the hæmoglobin could be roughly estimated by the colour of the blood, and from the stained film an approximate idea of the number of red cells could be obtained. As regards the leucocytes, we had to consider the total number and the proportion of the various kinds. The latter could only be judged of by carefully counting those on a stained film, and at least five hundred cells should be counted. The diagnostic results of systematic blood examinations were illustrated by a number of cases from Dr. Gulland's own experience. A patient had been subjected to a cosmetic operation on the face. The wound healed well, but on the fourth day the temperature rose and the man complained of a sore throat. There was an epidemic of influenza at the time, and the question arose whether the condition was septic, a simple tonsillitis, or influenza. The blood count on the sixth day showed 2,000,000 reds, 30 per cent. of hæmoglobin, and 24,000 leucocytes. Influenza was absolutely excluded by the leucocytosis, and tonsillitis by the anæmia, so that a diagnosis of septicæmia was made, which subsequent events confirmed. In the case of a woman the temperature rose about the tenth day of the puerperium, and there was some anæmia; locally, nothing was to be made out. The examination of the blood showed great diminution of the red cells and marked leucocytosis. The case had been thought to be one of pernicious anæmia, which sometimes developed after parturition, but the leucocytosis put this out of court, and led to the correct diagnosis of septicæmia. A number of other illustrative cases were described, the chief points brought out being the absence of leucocytosis in tuberculosis (unless complicated by a septic infection), in measles, and in influenza; its occurrence to a comparatively slight extent in typhoid, and its constant appearance in pneumonia even from the initial rigor, and in septic conditions. In septicæmia, too, a very great and rapid destruction of the red corpuscles was an invariable accompaniment. The study of the different leucocytes in disease was also well worthy of attention. The eosinophiles, for instance, were increased in asthma, thus affording a distinction between true spasmodic asthma and the dyspnoea of cardiac and renal disease. They were also increased in certain skin diseases, such as dermatitis herpetiformis and pemphigus, but the most marked eosinophilia was seen in trichinosis. This last was a comparatively recent observation, whose accuracy, however, had been confirmed; the eosinophiles might form as many as 68 per cent. of the total leucocytes. In conclusion, Dr. Gulland pointed out that in drawing conclusions from an examination of the blood, the other signs must not be lost sight of, and the possibility of a complication causing leucocytosis had also to be borne in mind. The paper was discussed by Drs. Alexander James, Chalmers Watson, and Foulis.

The retiring President then delivered a short valedictory address, in which he alluded in suitable terms to the losses the society had sustained through death during the past year. Among the thirteen members the society had lost were Sir William Jenner, John Moir, the father of the profession in Edinburgh, John Struthers, William Rutherford, and John Duncan. In passing the work of the session in review, the President remarked that they had had no papers bearing on the three great questions of public health—vaccination, the prevention of tuberculosis, and the prevalence of venereal disease—which were at present agitating the public mind.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD ON NOVEMBER 3RD, 1899.

Dr. J. B. BALL, President, in the Chair.

A NATIVE enema apparatus brought from the Upper Congo River, Central Africa, by Mr. W. D. Armstrong, was shown by Mr. McADAM ECCLES. The instrument

consisted of a medium-sized calabash, together with a small cane pipe, some three inches in length and the size of an ordinary lead pencil, fixed into the smaller end of the calabash, the fluid being allowed to run into the section by hydrostatic pressure.

Dr. MANSELL MOULLIN exhibited the ovaries removed from a patient, æt. 40. Both ovaries were enlarged, and the capsules thickened, one containing a cyst the size of a walnut.

Mr. PARDOE read a paper entitled

SOME MODERN METHODS OF TREATMENT IN CHRONIC URETHRITIS.

He said that great changes had taken place in the treatment of gleet during the past few years, due to improved methods of diagnosis, whereby we were enabled to treat the causes, and not merely the symptoms of this trouble. Before successful treatment occurred, localisation of the seat of the disease was essential. After explaining the methods in use which were best calculated to attain this object, he proceeded to describe various modes of treatment which were most likely to cure the diseased condition of the urethra, causing the gleet.

The paper was discussed by Drs. Bell and Lloyd, and Messrs. Swinford Edwards, and Bidwell. Mr. Pardoe replied.

Mr. SWINFORD EDWARDS read a paper on

URINARY OBSTRUCTION,

with cases illustrating some of its causes. He said that obstruction to the free flow of the urine was due to changes, either in the prepuce, the urethra, the prostate, or the bladder. The first case illustrating his remarks was one of stricture and impacted urethral calculus. The calculus was removed after urethrotomy with Otis's instrument, with complete success, the patient being able to pass water naturally for the first time for many years. The next case was that of a patient operated on by the author for stricture and perineal fistula. The last case narrated was that of a patient who suffered from obstruction due to an enlarged prostate; vasectomy was performed on one side with such an excellent result that it was proposed to at once perform the same operation on the opposite side. The paper was discussed by Drs. Bell and Lloyd and Messrs. Bidwell and Pardoe. Mr. Swinford Edwards replied.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.

ANNUAL GENERAL MEETING, OCTOBER 27TH.

Dr. BARCLAY BARON, President, in the Chair.

Dr. DUNDAS GRANT read notes of a case of

SUDDEN NERVE DEAFNESS

of the right ear in a woman, æt. 40. Prior to the attack she had menorrhagia and diarrhoea, with passage of blood from the bowel; and following the deafness, vertigo and nausea. The loss of hearing was chiefly for tones of the middle pitch. There was diminution of the pharyngeal reflex, exaggerated knee-jerk and comparative hemi-anæsthesia. The condition might be due to Meniere's disease, to anæmia of the auditory nerve or to hysteria. The hearing soon improved, and is now nearly normal.

Dr. DUNDAS GRANT showed a microscopical section of an epithelioma from the temporal bone of a male patient, æt. 45. The symptoms simulated necrosis of the temporal bone. A mastoid operation was performed with considerable relief, though the disease is slowly advancing.

Mr. BARK (Liverpool), remarked that he had lately seen an almost similar case with rapidly recurring aural polyp.

Mr. WINGRAVE thought that the growth commenced in an epidermal region.

The PRESIDENT delivered an address upon "Correlation of General Medicine and Laryngology, Rhinology and Otology."

The PRESIDENT showed a case of double uvula in a child associated with a curious defect of speech.

Mr. WINGRAVE considered the case to be one of cleft-

palate, and that the defective articulation was due to a different condition.

Dr. ABERCROMBIE again showed his case of "laryngeal papilloma" exhibited at the meeting in April. In the interval the tonsils and adenoids had been removed, and the growth afterwards treated with astringents; it is now much diminished in size.

Dr. WHISTLER showed a useful instrument for gauging the antero-posterior length of spurs.

Dr. REID for Dr. Orwin showed a convenient apparatus for applying continuous heat to different regions of the body.

Dr. TRESILIAN showed a case of new growth in the left maxillary antrum of a child, which produced considerable swelling of the left cheek. A discussion ensued as to the seat and the nature of the growth. He also read notes of (1) a case of "anosmia" following head injury; (2) a case of severe bilateral "acute otitis" with facial erysipelas.

Mr. NOURSE showed for Dr. Jakins, a case of "malignant growth of the larynx" in a phthisical patient.

Mr. WYATT WINGRAVE showed a case of "suppuration of the maxillary antrum." Persistent pain and discharge from the left nostril had followed the extraction of an upper molar twelve months before. On examination, a small opening was found at that site through which a fine probe could be passed into the left nostril. The opening in the alveolus was enlarged with a drill, and fetid pus evacuated.

Mr. WINGRAVE also showed a woman from whose left ear he had removed an ivory exostosis with a drill trephine. The deafness from which she previously suffered was relieved.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD ON OCTOBER 26TH, 1899.

The President, Dr. BURGESS, in the Chair.

Mr. PYE-SMITH showed a case of double coxa vara, together with a skiagraph, in a boy, æt. three. He was the youngest of seven children. There was evidence of rickets in him and in two of his brothers. He did not begin to walk till he was over two years old. He had a waddling gait and soon got tired. There was lordosis, slight eversion of the feet, great restriction of abduction, and some diminution of internal rotation. The great trochanters were an inch above Nélaton's line, the heads of the femora could not be felt, nor could the limbs be lengthened by traction. The diagnosis from morbus coxæ, and from double displacement of the hips was pointed out.

Mr. DALE JAMES showed an unusually fine example of tattooing on the chest and forearms.

Dr. ARTHUR HALL showed (1) a case of lichen planus, and (2) a case of serpiginous syphilide.

Dr. BURGESS showed (1) a case of Addison's disease; (2) a case of hemiatrophy resulting from injury to the skull in infancy; and (3) a tumour of the pons.

Dr. SINCLAIR WHITE read a paper on

ASEPTIC SURGERY.

He stated that no one now doubted the germ origin of septic diseases, but it was open to question whether in surgical practice the application of Lister's memorable discovery was as wide as it should be. The fault, if any, rested with our teachers, who should insist that failure to resort to measures for securing aseptic healing of wounds is tantamount to gross professional negligence. Sterilisation should be the first and, except in operations, through septic tissues, the only line of defence against septic micro-organisms. With efficient sterilisation the subsequent use of antiseptics is illogical and unnecessary. Heat, in the form of boiling water or steam, should be used for disinfecting instruments, ligatures, dressings, and towels. The skin, after thorough cleansing with a nailbrush, soap, and hot water, should be disinfected by a five minutes' contact with a 1 in 500 solution of biniodide of mercury in methylated spirit. An aqueous solution of the

same salt, 1 in 1000, should be used for disinfecting wounds. Ligatures should be of silk-worm gut, which in various sizes is applicable to all kinds of work. Vessels should be twisted rather than tied. Drainage was unnecessary and a source of danger in operations through healthy tissues. We do not drain the non-dependent lacerated wound filled with blood and bone dust produced in performing osteotomy, yet logically if drainage were ever required, in non-septic operations it should be resorted to here. Aseptic healing was a painless process, and deviation from this condition should excite suspicion of something having gone wrong. After operations the pulse and temperature should be carefully watched. A slight degree of fever during the first 48 hours was common, and need not cause anxiety; but, generally speaking, if all were going on well, the pulse and temperature should be normal on the evening of the third day, and remain so afterwards.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, November 5th, 1899.

CONTRA-INDICATIONS FOR THE USE OF CACODYLATE OF SODA.

At the Academy of Medicine, M. Gautier spoke on the preparations of cacodylate of soda, which when administered, he said, by the mouth or by the rectum, produced frequently symptoms of intolerance; the patient complained of cramps in the stomach, and the breath presented a garlic odour. These symptoms persisted several days after the suppression of the drug. He had also remarked that in individuals whose kidneys were perfectly sound, and *a fortiori* in those more or less impermeable, the prolonged injection of cacodylate of soda produced only temporarily albuminuria. On account of this inconvenience, due to an incomplete reduction of the agent in the intestine, M. Gautier renounced its employment by the mouth or the rectum in favour of hypodermic injections. Not only was the odour of garlic thus avoided, but also the other troubles. His formula was:—

Cacodylate of Soda, ʒiss.;

Phenicated Alcohol, ℥x.;

Distilled Water, ʒiijs.

Each syringe represented one grain of cacodylic acid, that was to say, the average dose for an adult in the twenty-four hours, but which might be doubled without danger on the condition that the treatment was suspended every eight or ten days during a lapse of time equal to the period the patient was under the treatment.

OPERATING PHIMOSIS WITHOUT CIRCUMCISION.

Dr. Lambert, of Dunkirk, operates phymosis without having recourse to the classical method of circumcision. His method is based on the principle that the phimosis comes from atresia of the mucous membrane, and that it suffices to effect a cure by simply increasing the diameter of the membrane without touching the cutaneous envelope.

After having prepared the parts by means of anti-septic irrigations, and made one or two injections of cocaine to obtain the necessary degree of anæsthesia, he seizes the prepuce with three forceps disposed at equal distances from each other. Taking a pair of scissors, he makes a small nick in the mucous membrane between each forceps, through which he introduces the fine point of the scissors, passing between the membrane and skin

and slits up to the sulcus. The prepuce thus dilated the glans becomes free. The small incisions are sutured, and the wound dressed in the usual way. The prepuce is then drawn over the gland, remaining thus dilated until the cicatrization is complete.

BEER YEAST IN VAGINAL GONORRHOEA.

Dr. Sireday is in the habit of employing in his hospital service beer yeast in the treatment of blenor-rhagia in women, according to the method of Dr. Landau, of Berlin, who employed it in leucorrhœa. A plug of cotton steeped in a mixture of fresh brewery yeast and sweetened water is introduced into the vagina and renewed daily. The treatment brings about a rapid modification of the mucous membrane, and a notable decrease of the secretion, although it did not effect a complete cure.

ERYSIPELAS AND ICHTHYOL.

A *confrère* publishes a series of 250 cases of erysipelas treated exclusively by him with ichthyol; the patients belonged to all grades of society, and their ages varied from six months to eighty-seven years. After having cleaned the surface with a plug of cotton wool wet with alcohol, he applies with the fingers an ointment of vaseline and ichthyol (13 to 30 per cent.) The treatment is renewed every four or six hours. Recovery was in every case rapid.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, November 4th, 1899.

SIX YEARS' EXPERIENCE IN KOCH'S TREATMENT OF TUBERCULOSIS.

In the *Zeitsch f. Hyg. und Infections Krank.* Dr. Fr. Krause records his experience in this department of therapeutics. The article, which is intended mainly for practitioners, shows what results can be achieved in the treatment of tuberculosis, and expresses the wish that the writer's experience may encourage others to take up the subject in a practical manner. He does not think it necessary that the method should only be used in special centres, and by experts only. He is of opinion that, if only slowly, the tuberculin treatment will work its way into general practice. He advises practitioners not to found extreme opinions regarding it, and not to advise their patients to decline to allow themselves to be treated by "this poison."

The writer has used tuberculin since 1892, and since the introduction of the new tuberculin he had used it. In the present article forty-one cases are recorded, which, as a basis for an opinion, are the more valuable, as they were under observation for years. Of the forty-one cases thirty were without complication, whilst in the remaining eleven the infection was mixed. In the later class the secondary infection was overcome in four cases, in seven it persisted in spite of all treatment. Of the patients in the first category three acquired a mixed infection that could not be overcome. In addition to the thirty cases of the first class there were the four of the second in whom the secondary infection was overcome, who were submitted to the tuberculin treatment. Of these thirty-four, twelve were at the time of writing temporarily cured, three were improved, two were still under treatment, three did improve but succumbed with second infection, one was improved but became second-

arily infected but was still living, three showed themselves unsuitable for tuberculin, in three the tuberculin was used for diagnostic purposes only, and one case got worse under the treatment. There remain twenty-seven cases in which the tuberculin was used therapeutically. Of these twelve were temporarily cured, thirteen improved, in one no change was observed after some weeks of the treatment, and one got worse. In this case the condition was due to excess of toxin, but the remedy itself was not the cause of this, but only its faulty administration. The writer concludes that when properly used tuberculin gives exclusively good results. He has formed no opinion as to which of the tuberculins is the better, the old or the new, but he records some observations on the point. Eleven patients had the new tuberculin, six of them exclusively. At first the writer thought that the T.B. had a more lasting effect, and protected the organism for a longer time than the other. Later on the new preparation appeared to affect the temperature less than the old, and when caution was used it set up no distinct reaction. On the other hand, the old preparation was such a powerful tonic with a moderate state of health and not far advanced phthisis, as to be second to none in the whole therapeutical armamentarium. For the future, Dr. Krause has decided to first of all treat all suitable cases with the old preparation, and then if the expected general effect has taken place, to at once go on with the new. He expressly remarks that the new preparation is not as harmless a remedy as has been believed by many. The greatest caution must be used to avoid intoxication.

Upon the whole, the writer's opinion is that with both tuberculins we have a specific remedy for the treatment of the disease. No further specific is needed at present, and efforts for the discovery of one would be better employed in discovering one for the prevention or treatment of mixed infection.

The remedy was given at long and short intervals. Twice within 34 hours, and at intervals of days, the dose sometimes was large, in one patient 500 mgrm., and several others received 300 mgrm. twice within 24 hours. From his own observation Dr. Krause concludes that the best method of tuberculin treatment is to keep to minimal reaction. It is quite enough if the thermometer goes a few points over 37 degs. C., provided, of course, that the previous temperature was below that figure. This limit can be adhered to with care and some experience. The pauses between two doses should be at least three days, generally more. All patients have slight pain at first in the injection punctures, and a little dragging in the limbs and slight malaise. If these symptoms do not disappear, or at least distinctly diminish after the fifth or sixth injection, and also if patients who have hitherto borne the treatment well present these symptoms, the syringe should be laid aside for a time.

The author concludes by discussing the method by which tuberculin acts beneficially. It is well known that tuberculin has a special affinity for the newly formed granulation tissue thrown up around tubercle centres. An inflammation is excited in the tissue, which finally ends by destroying it. If this dose is so accurately measured that only a local inflammation is excited, a strong leucocytosis is set up. If the process is repeated time

after time, the granulation tissue loaded with leucocytes becomes gradually converted into connective tissue. The tuberculous centre surrounded at first by a wall of leucocytes is gradually penetrated by connective tissue which, in further course, is converted into cicatricial bands. The enclosed products of cell decomposition along with the virulent tubercle bacilli are shut off by a strong wall of healthy lung tissue, and in the course of years the tubercle bacilli, so tenacious of life, gradually die off. A definite cure in the present instance, even if brought about by a specific remedy, is not the consequence of any acquired specific immunity, but is the result of an anatomical process.

ASPIRIN.

A new salicylic preparation (acetyl salicylate) has been recently introduced under the name of aspirin. It is in the form of crystalline needles, soluble in water at 37 degs. C. at the rate of 1 percent. In alcohol, ether, &c, it is about as soluble as other salicylic preparations. The most important distinction between aspirin and other salicylic preparations lies in the fact that it does not irritate the mucous surface of the stomach; further, it splits up so slowly in the gastric juice that it passes out of the stomach undecomposed and undergoes this process only in the alkaline intestinal juices, the blood, and in the tissue lymph. It is useful in all diseases in which salicylic acid and sodium salicylate have been employed, especially in gout, articular and muscular rheumatism, sciatica, dry pleurisy, &c. An agreeable form of administration is aspirin (one grain), sugar (three to four grains), stirred round in a little water and taken three or four times a day.

From the advantages it possesses over the crude salicylin preparation, its agreeable slightly acid taste, the absence of noises in the ears, irritation of the stomach when taken, aspirin is likely to come rapidly into favour.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, November 4th, 1899.

MORBUS BASEDOWII.

IN the discussion that followed Sittmann's paper on the subject of Basedowii's treatment, Mikulicz's eighteen operations for the radical relief of the disease were advanced. To vouch for the genuineness of the cases it was stated that Kast had diagnosed and previously treated them for such. These cases proved that the morbid changes of the gland were not constant in their anatomy, as different forms of the disease were met with which anatomists would divide into (1) diffuse hyperplasia, nodular, cystic, and composite. Macroscopically and microscopically, these changes are easily observed in the uncomplicated gland. All these cases had been treated internally for years before the operation, and 17 out of the 18 bore the operation well, one having post-hemorrhage from the four cut arteries that greatly endangered the life of the patient at the time, and which subsequently died. The hyperplasia of the arteries in this case was extreme.

Ten of the cases may be considered permanently cured, in eight of them it is four years since the operation was performed, and they are now well; while all of them were certainly improved by the operation.

In mild cases, where isolated nodules were present, enucleation was practised with tying of the arteries, but in very severe cases with double struma the resection can be performed with less danger.

Möbius could not conceive how the theory of the nerve system could be connected with a glandular adenoma.

He thought the greatest danger to the operation was the enfeebled heart, which often suddenly stopped with out the least provocation. To obviate the danger of bleeding and prevent the sudden abstraction of fluid from the body, Möbius prefers the bloodless operation of thermocautery.

Zabludowski thinks operating quite unnecessary, as bimanual massage will remove the fluid and thickening from the gland.

Kümmell was in favour of operating in the treatment of the disease, as two-thirds of all the cases were usually cured, while the others were certainly improved.

Bäumler asked if the enlarged heart met with in Basedowii was observed to constantly diminish after the operation? To which Reinbach instantly answered in the affirmative.

Ziemssen said he had often seen the disease cured by years of vegetable diet in elevated climates.

Rumpf said that all his operations showed gradually a normal heart, which was confirmed by Rehn.

THE LINE OF DEMARCATION BETWEEN MEDICAL AND SURGICAL TREATMENT.

At the opening meeting of the "Doctoren-Collegium" Gersuny read a long paper on the line of demarcation between medical and surgical treatment. Diagnosis was the fundamental element in the treatment of all diseases, although we had, even in the present time, Nature's therapeutic physician who could cure without our scientific diagnosis. Having diagnosed a case the prognosis has still to be considered. If a surgical case we should be able to forecast the course and result of the morbid process as well as the future results of an operation, giving also the chances of expectant treatment along with operative interference.

The latter implies a wide knowledge of surgery as practised at the present day. Not long ago an ovarian cyst was a perfect *noli me tangere*, till Spencer Wells proved it to be a fallacy. Carcinoma was another disease never to be touched, unless as an *ultimum refugium*, and to explore the abdomen would have incurred criminal censure; to-day, enterostomy for cancer of the bowel is a radical cure.

Surgical operations are often necessary as a prophylactic, such as hernia, when the so-called radical cures are performed, to avoid the use of a hernia belt, or where the patient is too poor to purchase one. The hernia may be safe enough of itself, but one day it may unexpectedly become irreducible and, subsequently, dangerous to life.

The contra-indication for all these advantages from surgical treatment is valvular disease of the heart as well as myo-degeneration.

PHYSIOLOGICAL INSTITUTE.

Vienna has now added to her large buildings another convenience to medicine. The Minister of Education, in opening the institution, said that Hyrtl and Rokitsky had made Vienna famous in medicine with few advantages compared with the present, which he hoped would stimulate the young to emulation. The rector next praised the works of Bruke; while Exner closed with a general description of the new building.

Special Articles.

THE LAWS OF WAR RELATING TO MEDICAL MEN AND WOUNDED.

THE practices of the ancient world, and even the opinion of some modern writers on public law, made no distinction as to the means to be employed to accomplish the end for which arms had been taken up. Even Bynkershoek and Wolff, who lived at the beginning of the eighteenth century, assert the broad principle that anything done against an enemy is lawful; that he may be destroyed, though unarmed and defenceless; that fraud, and even poison, may be employed against him; and that an unlimited right is acquired by the victor to his person and property. Such, however, was not the sentiment and practice of enlightened Europe at the period when they wrote, since Hugo Grotius had long before inculcated milder and more humane principles, which Vattel subsequently enforced and illustrated, and which are adopted by the unanimous concurrence of all the public jurists of the present age.

Formerly, when nation attacked nation, the whole inhabitants of the hostile State were regarded as liable to the rigours of warfare; but at the present day not only old people, women and children are regarded as exempt from the violence of warfare, but also in general all those subjects of the hostile State who do not bear arms or who take no active part in hostilities, and even those who follow the enemy's camp, but take no part in hostilities—such as medical men, commissaries, and all who can be strictly classed as non-combatants. In the case of enemies rendered harmless by wounds or disease, the growth of humane feeling has long passed the simple requirement that they shall not be killed or ill-used, and has cast upon belligerents the duty of tending them so far as is consistent with the primary duty to their own wounded. But the care which the wounded of a defeated army thus obtain is necessarily inadequate to their wants, and the usefulness of surgeons on both sides is hampered by their liability to be detained as prisoners. A step of which the value in mitigating the unnecessary horrors of war cannot be over-estimated would therefore be made if a general and sufficiently full understanding were arrived at as to the treatment of sick and wounded, and of persons and things engaged in their service, which should give free scope, as far as the exigencies of war permit, to the action of everyone whom duty or charity may enlist in the mitigation of suffering.

Under the Convention of Geneva of 1864 the greater part of the European States bound themselves to observe a code framed with this object, and the accession of nearly all the civilised States of the world has converted its provisions into rules of overwhelming authority. This Convention was signed on behalf of Switzerland, Baden, Belgium, Denmark, Spain, France, Hesse-Darmstadt, Italy, Netherlands, Portugal, Russia, and Wurtemberg. The following Powers have also acceded to it:—Argentine Republic, Austria, Bavaria, Bolivia, Bulgaria, Chili, Great Britain, Greece, Japan, Mecklenburg-Schueren, Montenegro, Persia, Peru, the Pope, Roumania, Russia, Salvador, Saxony, Serbia, Sweden and Norway, Turkey, United States. The articles are as follows:—

"Art. I.—Ambulances and military hospitals shall be acknowledged to be neuter, and as such shall be pro-

tected and respected by belligerents so long as any sick or wounded may be therein. Such neutrality shall cease if the ambulances or hospitals should be held by a military force.

"Art. II.—Persons employed in hospital and ambulances, comprising the staff for superintendence, medical service administration, transport of wounded, as well as chaplains, shall participate in the benefit of neutrality whilst so employed, and so long as there remain any wounded to bring in or to succour.

"Art. III.—The above persons may even, after occupation by the enemy, continue to fulfil their duties in the hospital or ambulance which they serve, or may withdraw in order to rejoin the corps to which they belong. Under such circumstances, when these persons shall cease from their functions, they shall be delivered by the occupying army to the outposts of the enemy.

"Art. IV.—As the equipment of military hospitals remains subject to the laws of war, persons attached to such hospitals cannot, in withdrawing, carry away any articles but such as are their private property. Under the same circumstances, an ambulance shall, on the contrary, retain its equipment.

"Art. V.—Inhabitants of the country who may bring help to the wounded shall be respected, and shall remain free. The generals of the belligerent powers shall make it their care to inform the inhabitants of the appeal addressed to their humanity, and of the neutrality which will be the consequence of it. Any wounded man entertained and taken care of in a house shall be considered as a protection thereto. Any inhabitant who shall have entertained wounded men in his house shall be exempt from the quartering of troops, as well as from a part of the contributions of the war which may be imposed.

"Art. VI.—Wounded or sick soldiers shall be entertained and taken care of, to whatever nation they may belong. Commanders-in-chief shall have the power to deliver immediately to the outposts of the enemy, soldiers who have been wounded in an engagement, when circumstances permit this to be done, and with the consent of both parties. Those who are recognised after their wounds are healed as incapable of serving, shall be sent back to their country. The others may also be sent back on condition of not again bearing arms during the continuance of war. Evacuations, together with the persons under whose directions they take place, shall be protected by an absolute neutrality.

"Art. VII.—A distinctive and uniform flag shall be adopted for hospitals, ambulances, and evacuations. It must on every occasion be accompanied by the national flag. An arm badge shall also be allowed for individuals neutralised, but the delivery thereof shall be left to military authority. The flag and the arm badge shall bear a red cross on a white ground. (Turkey uses a red crescent.)"

The following additional articles were signed at Geneva on October 26th, 1868. The chief articles are as follows:—

"Art. I.—The persons designated in Article II. of the Convention shall, after the occupation by the enemy, continue to fulfil their duties, according to their wants, to the sick and wounded in the ambulance or the hospital which they serve. When they request to withdraw, the commander of the occupying troops shall fix the time of departure, which he shall only be allowed to delay for a short time in case of military necessity.

"Art. III.—Under the conditions provided for in Articles I. and IV. of the Convention the name (ambulances) applies to field hospitals and other temporary establishments which follow troops on the field of battle to receive the sick and wounded.

"Art. V.—In addition to Article VI. of the Convention, it is stipulated that, with the reservation of officers, whose detention might be important to the fate of arms and within the limits fixed by the second paragraph of that article; the wounded fallen into the hands of the enemy shall be sent back to their country, after they are cured, or sooner if possible, on condition, nevertheless,

of not again bearing arms during the continuance of the war.

"Art. VI.—The boats which, at their own risk and peril, during and after engagement, pick up the shipwrecked or wounded, or which, having picked them up, convey them on board a neutral or hospital ship, shall enjoy, until the accomplishment of their mission, the character of neutrality as far as the circumstances of the engagement and the position of the ships engaged will permit. The appreciation of these circumstances is entrusted to the humanity of all the combatants. The wrecked and wounded thus picked up and saved must not serve again during the continuance of the war.

"Art. VII.—The religious, medical, and hospital staff of any captured vessel are declared neutral, and on leaving the ship may remove the articles and surgical instruments which are their private property.

"Art. VIII.—The staff designated in the preceding article must continue to fulfil their functions in the captured ships, assisting in the removal of wounded made by the victorious party; they will then be at liberty to return to their country in conformity with the second paragraph of the first additional article.

"Art. IX.—The military hospital ships remain under martial law in all that concerns their stores; they become the property of the captor, but the latter must not divert them from their special appropriation during the continuance of the war. The vessels not equipped for fighting which during peace the Government shall have officially declared to be intended to serve as floating hospital ships, shall, however, enjoy during the war, complete neutrality both as regards stores, and also as regards their staff, provided their equipment is exclusively appropriated to the special service on which they are employed.

"Art. XI.—Wounded or sick sailors, and sailors when embarked, to whatever nation they may belong, shall be protected and taken care of by their captors. Their return to their own country is subjected to the provisions of Art. VI. of the Convention, and of the additional Art. V.

"Art. XII.—The distinctive flag to be used with the national flag, in order to indicate any vessel, or boat which may claim the benefits of neutrality in virtue of the principles of this Convention, is a white flag with a red cross. Military hospital ships shall be distinguished by being painted white outside with green streaks.

Art. XIII.—The hospital ships which are equipped at the expense of the aid societies recognised by the Governments signing this Convention, and which are furnished with a commission emanating from the Sovereign, who shall have given express authority for their being fitted out, and with a certificate from the proper naval authority that they have been placed under his control during their fitting-out, and on their final departure, and that they were then appropriated solely to the purpose of their mission, shall be considered neutral, as well as the whole of their staff. They shall be recognised and protected by the belligerents. They shall make themselves known by hoisting, together with their national flag, the white flag with a red cross. The distinctive mark of their staff, while performing their duties, shall be an armlet of the same colours. The outer painting of these hospital ships shall be white with red streaks. These ships shall bear aid and assistance to the wounded and wrecked belligerents without distinction of nationality. They must take care not to interfere in any way with the movements of the combatants. During and after the battle they must do their duty at their own risk and peril. The belligerents shall have the right of controlling and visiting them; they will be at liberty to refuse their assistance, to order them to depart, and to detain them if the exigencies of the case require such a step. The wounded and wrecked picked up by these ships cannot be reclaimed by either of the combatants, and they will be required not to serve during the continuance of the war."

The Convention of St. Petersburg condemned the use of explosive bullets, and other Conventions have attempted to alleviate, as far as possible, the frightful horrors of war.

The Operating Theatres.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.

OPERATION FOR CATARACT.—Mr. H. WORK DODD operated on a man, *æt.* 58, who was admitted for imperfect vision. On examination of the right eye with oblique illumination (the pupil having been dilated with gutta homatropinæ et cocaine, which is found to be the quickest mydriatic), there was found to be complete opacity of the crystalline lens, so complete that there was no shadow thrown on to the opacity of the lens by the iris. The opacity also precluded any of the normal red reflex of the fundus being seen with the ophthalmoscope at a distance. Perception of light was good. The other eye on being examined by the same method was discovered to be cataractous, but not advanced sufficiently for operation, though vision was much depreciated. Operation on the right eye was therefore determined upon, though Mr. Dodd pointed out at the moment of operation that some departure from the normal might be expected because of the appearance of isolated dots of denser opacity in the cataract indicating probably calcareous degeneration. The patient having been cocaineised with drops of cocaine solution (*gr.* 4 to 3) applied 3 or 4 times, the eye was first thoroughly disinfected with perchloride lotion (1 in 5,000) from a douche, particular attention being paid to the caruncular region, the lids and surrounding skin were also thoroughly washed; the patient having a very deep orbit and the speculum not lying well in position, Mr. Dodd determined to do the operation using only Mr. Critchett's nature's speculum (that being the retraction of the upper lid by the third finger of the forceps hand, which is sufficient to expose the eye for operation, and which has also the advantage of immediate and sudden relaxation in case of necessity). Von Graefe's knife was employed, the point of puncture was a modification of what is known as the 3 m.m. operation, being made at the corneo-scleral junction, the counter puncture being at a corresponding point on the opposite side of the cornea. With slow quiet strokes the knife was carried upwards to within about a mm. of the superior part of the cornea when the edge was turned forwards and the incision completely finished, with the edge to the front. Iridectomy forceps were then introduced, and some little difficulty was experienced in withdrawing the pupillary margin of the iris through the corneal wound owing to adhesions between the iris and the anterior capsule of the lens due to old inflammation; ultimately a sufficient iridectomy for the passage of the lens was attained, the anterior capsule of the cataract was lacerated in a T-shaped manner, and then, the lids being retracted now by an assistant, the operator placing one tortoise-shell scoop below the cornea and another behind the wound of the cornea above, endeavoured with carefully graduated pressure to cause the lens to leave its capsule and the eye. Owing to past inflammatory adhesions (above mentioned) this was attended with much difficulty. An instrument was, therefore, passed in to separate the iris and the lens, and then again pressure was tried as before; the lens with difficulty came out enclosed in its capsule, and this with no escape of vitreous humour, though the operator pointed out how

near this structure was to the mouth of the wound. The ocular region having been now again thoroughly cleansed with perchloride solution, both eyes were closed by a light pad of cyanide lint held in position with two strips of sticking plaster, and the patient removed to bed. Mr. Dodd pointed out that the partial loss of vitreous humour, though apparently regarded by the older ophthalmic surgeons with equanimity, was in reality a serious matter, as eyes from which the vitreous humour had been lost, though they might heal well and plump out with fluid secretion to almost a normal tension and recover very good vision, yet persistent inflammatory irritation, shrinking of the globe, and after a time loss of vision were common results. He said that by keeping the incision rather on the corneal side of the corneo-scleral junction, and taking care that the counter puncture was in the same region, and not too far back into the sclera, as is often the case, opening of the vitreous chamber might generally be avoided, though it ought to be said that in some degenerated eyes the vitreous was so extremely fluid that it was lost even when the greatest skill and care were exhibited.

It is satisfactory to state that the patient has done extremely well, and, as far as can be seen three weeks after the operation, has recovered comparatively good vision.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 8, 1899.

PUBLIC ANALYSTS AND PLURALITIES.

In a recent article we commented upon the rejection in a magistrate's court of the evidence of a well-known public analyst on the ground of his not having based his testimony upon a personal analysis. Amongst other things we freely criticised the system of pluralities that has become the rule rather than the exception as regards public analysts. As the opinions then advanced appear to have given rise to more or less misconception in certain quarters it may

be well to add a supplementary statement dealing with some aspects of the functions and tenure of those important official posts. First of all it would be highly desirable to define the position of a public analyst. Is he simply a chemist, or is he also a bacteriologist? In the case alluded to above, the disallowed evidence bore upon a bacteriological analysis. If the position of public analyst does not include that special and highly technical branch of biological research, then our friends the lawyers will probably have something to say in the matter. This point is of considerable importance, because the time and special skill required in bacteriological examinations are most exacting elements, and would have to be added to complicated chemical processes already demanding patient accuracy and thoroughness on the part of the operator. In any case it is interesting to inquire on what footing the analyst appears in Court. A gentleman who is entitled to speak with authority has sent us a communication in which he says emphatically that public analysts have nothing to do officially with medico-legal work. If that proposition be accepted it is clear that any such analyst gives court evidence merely as a private expert. But the position is by no means so simple as our correspondent would have us believe. It is true that a public analyst may be called in to give evidence in a case outside his own district, in which event he appears in the witness box as an expert pure and simple, to give either corroborative or rebutting testimony. The analyst is an officer of the Local Government Board in the restricted sense of the condition laid down in the Sale of Food and Drugs Act, 1875, that all appointments and re-appointments are subject to the approval of the Local Government Board. The Act lays down that in every district a competent person may be, and if required by the Local Government Board, must be, appointed public analyst. The appointment is made by the Town Council of any borough having a separate Court of Quarter Sessions, or a separate police establishment, while all parts of the country not included in the foregoing are provided for by the County Council. The salary, wholly or in part, is paid by the local authority, and it appears to us to be an untenable position to claim that if a public analyst goes into court to sustain a prosecution undertaken by the authority by whom he has been appointed that he does not give evidence in an official capacity. With regard to the co-tenure of the post of public analyst with that of the medical officership, it is open to grave doubt whether such a dual appointment is not against the interests of the community. A Medical Officer of Health, to be efficient, should be fully occupied with the sanitary supervision of his district, and in that case could not spare the time for laborious analyses. It is physically impossible for a man, conscientiously and adequately to do his duty as public analyst to half-a-dozen districts, while at the same time he is acting as Medical Officer of Health, lecturer at a medical school,

medical adviser to various boards, and as holder of a number of minor paid or honorary positions. The Local Government Board discourages this species of co-tenure, but we would go further, and render them illegal. Plurality in the posts of public analyst in extreme instances amounts to a hardly less abuse. It is readily to be understood why the holding of more than one appointment as public analyst should be countenanced by the Local Government Board, inasmuch as by the combination of two or three districts laboratory expenses could be lessened, and a better salary could be offered as an inducement to a competent man. When a single chemist, however, undertakes the duties of public analyst to five, six, eight, or any number up to thirty boroughs or counties, we hold that the whole thing degenerates into a farce. Personal supervision is impossible, and efficiency is tossed on the horns of a dilemma, for either the public analyst or the counties and districts for which he acts must be neglecting his duty. In any single borough or county of moderate size the proper enforcement of the Food and Drugs Act, would imply a number of analyses more than enough to occupy the whole time of any man, however diligent. It is enough to make any plain man gasp and stare with astonishment to find that a busy and distinguished Irish Medical Officer of Health holds the post of public analyst to six boroughs and twenty-four counties. In London another Medical Officer of Health, who is lecturer to a medical school, acts as analyst to two counties, two boroughs, and four large and crowded Metropolitan parishes. It will be interesting to hear any defence that may be forthcoming to pluralities of that kind. Of course, the convenience and economy of using one laboratory and staff for several districts is obvious. Then there is the question of evidence. It seems abundantly clear that the lawyers will, in future, insist on all such medico-legal evidence given in court being the result of a personally conducted analysis. At least, any legal adviser who neglected to take that line, after a recent decision, would be neglecting the interests of the client whom he was defending. The phases of this important subject are by no means exhausted, and we propose to deal further with the matter at some future time.

THE NEW CHARTER OF THE ROYAL COLLEGE OF SURGEONS, ENGLAND.

It is not to be disputed, of course, that the New Charter applied for by the Royal College of Surgeons, England, will, if granted, confer distinct advantages upon the College. In brief, it will enable the Council to endow distinguished persons, worthy of honours, with an honour which, under the circumstances of the case, could not fail to be highly prized. Again in making application for powers in this direction, the Council have merely endeavoured to fall into line with other corporations and institutions, whose charters enable them to confer honorary distinctions. All those Fellows and members of the College, then, who

have the interests of their College at heart, will undoubtedly hope that the Privy Council will accede to the petition for the New Charter which has been made. Practically the draft charter consists of six clauses. The first deals with the main object thereof, namely, the power to confer honorary fellowships which shall not, at one and the same time, exceed fifty in number. The second determines that the election of a honorary Fellow shall be by a majority of votes in the Council. The third, that no fee shall be payable by any honorary Fellow in respect to his election or diploma. The fourth that no honorary Fellow shall be eligible as a member of the Council or Court of Examiners, or be entitled to vote at any election of a member or members of the Council, but that he shall have and enjoy other such of the other corporate rights and privileges attaching to the Fellowship of the College. The fifth, that no honorary Fellow shall thus acquire any right to practice surgery, or to be registered as a registered medical practitioner, and sixthly and last that in so far as concerns the election admission rights and privileges of Honorary Fellows, and all matters relating thereto, these will be regulated by the existing, bye-laws, charters, and regulations of the College. Thus it will be gathered from this brief statement of the objects and details of the New Charter that there is nothing which can be regarded as detrimental to the interests, either of the "body corporate," or the College itself. All the Council desire to attain is the power to confer an honour upon distinguished individuals who have been honoured by other corporations. It is more than likely that they have been inspired to embark upon this undertaking by the fact that the Royal College of Physicians, London, are empowered by their charters to confer an Honorary Fellowship of their college upon distinguished persons. The latest to receive this honour was the Prince of Wales. We may safely conclude, then, that as soon as the Royal College of Surgeons are in the position to endow a liege subject of the Queen with an Honorary Fellowship of the College, no time will be lost in following the example of the sister college, and in presenting the Heir-Apparent with a diploma enabling him to sign himself F.R.C.S. We cannot suppose that any difficulties will be raised against the petition which has been made for the Charter. Practically, no contentious matter is involved in it, and it has received the unanimous support of the "body corporate." It is true that a section of the members were desirous of introducing extraneous questions into the Charter, with a view to settling points in connection with college politics, which are annually paraded at the November meeting of the College, but the Council wisely and firmly intimated that the occasion would be an inopportune one for following such a course. Obviously, if any contentious matters had been incorporated in the application for the Charter grave difficulties would have been introduced into the case.

THE PSYCHOLOGY OF JURORS.

THE confidence which trial by jury inspires in the breast of the average citizen is doubtless based on the assumption that the verdict of twelve men, honest and true, stands a good chance of being free from fear, favour, and affection, as well as from the whims, cranks, and oddities of the individual juror, especially as care is taken to exclude the better-educated classes of the community from the jury panel, presumably in order to prevent their exercising too predominant an influence over their less-educated colleagues. If, however, we inquire into the mental condition of the average juror one cannot but be struck by the fact that he is fitted neither by occupation nor training to discharge the highly responsible duties entrusted to him. As Dr. Crothers observed in an address recently delivered before the New York Medico-Legal Society, while none would question the motive and intent of the average juror to be just and fair in his conclusions it would seem that certain conditions and surroundings make it impossible in most cases, either to understand the case before them or the principles of equity involved. The assumption that the twelve men set apart for this duty are endowed with a large and sufficient mental capacity for the discernment of truth and justice is far from being true in reality. On the contrary, they are, oftener than not, naturally incompetent, and they are, moreover, generally placed in the worst possible conditions and surroundings to exercise even average common sense in any disputed case. Take a typical trial in which twelve men, many of them recruited from the out-door labouring class, unaccustomed to any form of continuous mental work, obliged to remain sedentary in a stuffy court-house, and constrained to listen to a lot of conflicting expert evidence wholly beyond their ken. What little gleam of light enters their mind as the result of perfunctory attention to the evidence is ruthlessly destroyed by the interested *ex parte* pleading of the advocates. Let us remember that in all probability not one of these twelve men would have been chosen to take charge of any trust or to decide on any matter outside of his every day life, simply because, on general principles and from common sense observations, he would have been clearly incompetent. Let us bear in mind also the difficulty which most of us experience when called upon to concentrate the mind for any length of time on a lecture or discourse, and we shall form a faint idea of the hopeless confusion into which the minds of the average jury must fall after a few hours of such an unaccustomed strain. Suppose the case to be prolonged for several days, ere which time the body begins to suffer from change of habits and enforced inaction and more than shares in the mental lassitude. Let us ask ourselves then what probability there is of the twelve arriving at a clear and impartial opinion on the questions put to them by the judge. Having done this we shall not be surprised at the generally received opinion that a law suit is largely a matter of chance—a "toss up," as a sporting lawyer would

say. In a technical civil action, assessors might assist the jury in arriving at an approximately correct conclusion, but in criminal cases—the most important from a social point of view—the intervention of assessors would not be tolerated except in the person of the judge, who, indeed, finds himself in most instances obliged to come to the assistance of the jury. Dr. Crothers' description of the jury during a prolonged trial, ought to rank high as a study of physiognomy. As the case goes on, he observes, the faces of the jurors become pale or unduly flushed, the eyes lose their intelligence, and become vacant and watery. Some show restlessness by frequent changes of position, others become somnolent and inclined to stolidity, others, again, are constrained and seem to be struggling to keep up some degree of dignity, and all show signs of that confusion of mind which comes from changed surroundings and functional disturbances resulting from confinement and mental exhaustion. This, he remarks, is the natural outcome of placing untrained men in positions which they cannot fill, and requiring of them clear judgment under circumstances in which it is almost impossible to act normally.

Notes on Current Topics.

Consultants at the Seat of War.

SURPRISE has been expressed in certain quarters that Mr. Frederick Treves should have decided to proceed to the seat of war in South Africa. But we understand that the "offer for his services made to him by the Government was such that he could not possibly refuse." Possibly, it would be no monetary consideration which could induce Mr. Treves to transfer himself for an indefinite period from his active surroundings, nor can a surgeon in his position afford to act merely upon the dictates of patriotism. Possibly, therefore, the intimation of an honour, as a reward for services rendered in the war, has made the offer of the Government under these circumstances, an impossible one to reject. If this be so, we may assume at once that any such recognition of Mr. Treves' position as a representative British surgeon will be warmly welcomed by the profession generally. Meanwhile a correspondent is anxious to know how the presence of Mr. Treves in South Africa will affect the appointment of Sir William MacCormac. The latter surgeon is proceeding to the Cape as consulting surgeon to Her Majesty's Forces at the seat of war. But this appears to be the official title which has also been conferred upon Mr. Treves. Hence it has naturally been asked, will the President of the Royal College of Surgeons take precedence to his younger colleague, or will the two appointments be on an equal footing from an official point of view? The War Office have made no statement upon this point, and, therefore, it is only possible to speculate concerning their intention in the matter. We learn that the President of the Royal College of Surgeons, Ireland, Mr. R. L. Swan, has also placed his services

at the disposal of the Government. This action on the part of the Government must not be construed as indicating any want of confidence in the Army Medical Staff, but it is a matter of public notoriety that this department is greatly under-manned, and in any event is sure to be greatly overworked.

Lesions of the Skin and Carcinoma.

THE eczematous condition of the nipple, which, since Sir J. Paget drew attention to it, is admitted to precede carcinoma of the breast, has raised the question of the possibility of the existence of a pre-cancerous stage of cancer, and the theory receives a good deal of support from the connection which appears to exist between the two diseases in this instance. But further confirmation in this regard has lately been brought forward, curiously enough, also in connection with a lesion of the skin. Hartzell has collected a series of cases of psoriasis, treated by arsenic, in which epithelioma ultimately developed. So far the series consists of eleven, and the interest of the cases is naturally centred in the etiology of the malignant degeneration. Is the disease caused by the arsenic, or is it only another proof of the existence of a pre-cancerous stage? As workers in arsenic have been proved to possess no special predilection for cancer, it is possible that the reasonable theory as to the existence of a pre-cancerous stage of cancer is, in this instance, as in the former one, correct. The belief that cancer is a parasite disease would in no sense be lessened by the adoption of this theory, for the natural conclusion is that there must be some special preparation of the soil before it can become a cultivation medium for the development of cancer micro-organisms.

Paralyses following Anæsthesia.

PARALYSES supervening after general anæsthesia, the so-called post-anæsthetic, or post-operative paralyses, of which numerous instances have been placed on record, belong to several distinct categories, but none of them can reasonably be attributed to any toxic action on the part of the anæsthetic itself. First, among these strictly peripheral paralyses are those which may be dismissed as mere coincidences, such for instance as hemiplegia from rupture of a cerebral blood-vessel, or mere functional paralysis, mono or hemiplegic. Excluding cases in which a nerve, or several nerves, have been cut, or otherwise injured in the course of the operation, the most common variety of post-operative paralysis is that due to stretching of or pressure upon a nerve trunk, brought about in some instances, by prolonged decubitus in a faulty position, as for instance elevation and extension of the humerus which then presses upon the brachial plexus, or allowing a limb to hang over the edge of the table, and so on. Then, too, injurious pressure may be exerted by clamps or tight straps over the shoulders or lower extremities. It is important that the attention of surgeons should be called to these accidents in order that attention may be paid to the question

of posture during anæsthesia. While these pressure paralyses are usually recovered from in a short time it must not be forgotten that in some cases they have been known to persist for months and even years, indeed the disability may even be permanent. The duration of the paralysis depends, of course, upon the amount of injury inflicted upon the nerve trunk and upon the recuperative power of the individual. Inasmuch as there are no means of estimating these factors in any given case it behoves us to bear this contingency in mind when preparing a patient for operation.

The Health of Cornwall.

WE learn from the *Western Morning News* that for the first time since 1892 the Sanitary Committee of the County Council have issued a report on the health of the county for a complete year. Though somewhat belated the report is none the less welcome, for it will direct attention to a condition of things which should attract more than passing notice. The birth rate for the county is low, nearly five per thousand below that for the whole country, but the death rate of infants under twelve months is as high as 15·6 per cent. in the rural, and 19·3 in the urban, districts, rates which are notably higher than those of large towns, such as Plymouth, Manchester, Birmingham, &c. Diarrhoea and whooping-cough contributed largely to this abnormally high death rate, due in large measure to improper feeding. It is a sad commentary on our present attitude towards phthisis that no less than 437 deaths, or one in thirteen, were ascribed to this disease, the death rate from this cause in the towns being exactly double that for the country. We are promised that in future the reports will be made annually at an earlier date, and there can be no question that these reports, when explained and commented on by the local press, constitute a valuable means of educating the public on matters in which they are deeply interested.

The Northampton Guardians.

THE Northampton Guardians, who had the good sense to "climb down" when the Local Government Board applied for a writ of mandamus in respect of their refusal to appoint a vaccination officer, made an unsuccessful endeavour last week to evade payment of the costs on the ground that they had only wished to raise a constitutional question without any intention of being contumacious. The judges, however, decided the case against them, and it is quite possible that the law-abiding citizens of Northampton may resent being called upon to pay a large bill of costs in addition to their own legal expense for the doubtful privilege of fighting a government department.

The Bertillon System.

THE honour of having introduced the anthropometric system known under the above name is apparently not rightly attributed to M. Bertillon. According to a correspondent in an American contemporary, the system in question is really that designed by Broca, and it is added that other autho-

rities have devised better and simpler methods than the one for which M. Bertillon enjoys the credit. We do not know what M. Bertillon would have to say to this criticism, but no one, we suppose, has yet forgotten the sorry figure which this anthropometric authority cut at the Rennes trial of the unfortunate Captain Dreyfus. If, however, there are "simpler and better methods" than the one known as "Bertillon's" for the detection of criminals, we would urge that the authors of them would be conferring a favour upon the police authorities of the world by making them known.

Sleeping in Corsets.

To describe the vagaries of fashion in woman's dress from a physiological point of view would be to pen a scathing satire on the foibles of the sex. From recent letters published in a public journal we learn that one of the chief causes why a woman cannot take the short, smart little steps that mark the progress of a tightly-shod and high-heeled boot, is because she has not worn them from youth upwards. Anyone who profers cramped artificial gait of that kind, to say nothing of the associated internal organic complaints, would probably defend the dyeing of hair, the rougeing of cheeks, and all other methods of improving Nature's work, and would defend their use in the nursery or at the boarding-school. Heaven defend our school girls from such a fate. So far their most serious physical handicap consists in the corsets that a distorted feminine judgment still generally insists upon their wearing. About that extraordinary implement of attire—for that is what it amounts to—the one thing that prevents it killing off a considerable proportion of the female population of the United Kingdom lies in the fact that during sleep the body is allowed to resume the shape and movements with which that most perfect product of Nature has been endowed. It will come as a shock to most of the sterner sex to learn that the practice of sleeping in stays is discussed in some quarters as an accepted fact. In the directions given by one foolish dame the lady is directed to stand up; right and hold an old-fashioned backboard, bracing back the shoulders while being laced. This method is said to obviate entirely the necessity of sleeping in corsets. The picture thus raised reminds one forcibly of the mediæval rack, with an innocent schoolgirl as the victim instead of a Christian martyr or a criminal.

Premature Burial.

THE Society that boasts the somewhat high-sounding title of the London Association for the Prevention of Premature Burial has passed a number of resolutions which have been duly published for the behoof and guidance of the public. It seems that a draft bill for the better prevention of premature burial was prepared by this society some two years ago, and the executive have not yet given up hope that the Legislature will give practical shape to their recommendations. One of their resolutions states that "notwithstanding

the indifference shown to the question by a portion of the public and of the medical profession, the dangers of premature burial are sufficiently great to warrant the attention of every thoughtful person." Quite so, but can the Association with the long name mention any scientific man of unquestioned reputation and standing who is convinced that the existence of any case of live burial has ever been proved by positive and unquestionable evidence? The final resolution says that "the cases that have been indisputably proved to have taken place warrant the conclusion that the danger is far greater than many persons are disposed to think." The whole question was discussed some years ago in a series of articles that appeared in the columns of THE MEDICAL PRESS AND CIRCULAR, and that have since been reproduced in book form under the title "Premature Burial, Fact or Fiction?" The logical weakness of the Society for the Prevention of Premature Burial lies in the fact that they have omitted to prove in the first place that such an occurrence has ever taken place. Of assertions and vague stories there is a multitude; of sane and exact evidence and reasoning none.

Death under Chloroform.

A DEATH under chloroform occurred last week at the Birmingham Children's Hospital, the victim being a child, æt. nine, who was about to undergo the removal of post-nasal adenoids. We were under the impression that laryngologists in solemn conclave assembled had more than once declared the use of chloroform for this purpose to be attended by unavoidable and unnecessary risk. Certain is it that if carried out by skilled hands the operation is one which can be accomplished satisfactorily under nitrous oxide, and this prompts the question why the more lethal anæsthetic should be employed instead of the comparatively harmless gas.

Port Sanitary Work.

THE half-yearly report of the medical officer of the Port of London may be taken as a fair type of the activity and thoroughness of the preventive sanitary service carried on at the ports of the United Kingdom. During the period under review no less than 17,232 vessels were inspected. In 1,431 it was found necessary to enforce cleansing operations. Three hundred and forty structural alterations were carried out in 315 vessels with a view to improvement of ventilation, lighting, heating, and the storage of drinking water. During the half-year the medical officers visited 5,061 vessels at Gravesend in conjunction with Her Majesty's Customs, and examined 7,626 passengers and 16,141 members of crews. At Sheerness a further 128 vessels were medically inspected. Sixty-four cases of infectious disease were dealt with, including small-pox, scarlet fever, diphtheria, and enteric fever. Dr. Collingridge reports a gross case of overcrowding on board a Danish steamer, which arrived with 176 foreign immigrants, all of whom were berthed together in a scandalously small space. The rational system of

port sanitary prevention that has gradually been evolved in England is one of which we may well be proud. The arrival of cases of such deadly infection as cholera and plague can now be viewed with complacency, a statement that could be made of no other country in the world. The absurdity of the old order of things which depended on fetish fumigations and quarantine and military cordons has been lately demonstrated at Oporto. Dr. Collingridge is to be congratulated on the success with which he administers a vast and laborious organisation.

Lyddite as a Logical War Material.

If the object of war be to destroy as many of the enemy as possible then it follows that the more effective the means of destruction employed the sooner will that object be obtained. There is something to be said in favour of the contention that fewer men are killed nowadays in a big action than in the old times of hand-to-hand fighting. In the present war at the Cape the terrible devastation caused by lyddite shells has been brought into evil prominence. The lyddite is packed in a shell and fired by a percussion fuze. It is obtained by the fusion of picric acid, which is in turn manufactured by the action of nitric acid upon phenol. Its explosion creates an area of havoc far wider than that due to the ordinary shell charged with powder and shot. In the case of lyddite the resulting deaths are for the most part due to the terrific concussion of air, which has been known to kill a man at a distance of two hundred yards. To a limited extent, therefore, the lyddite is less barbarous than the ordinary shrapnell shell inasmuch as its victims are killed outright. Beyond a doubt in this explosive we have one of the most terrible war materials yet introduced into warfare. Yet its use has not been forbidden by the usages of civilised nations, who appear to have drawn the line as yet simply against the explosive bullet. It is quite possible, as some folk maintain, from a philosophic point of view that developments of the lyddite type advance the day of the millennium of universal peace simply because they will sooner or later render war impossible.

The Two Medical Defence Unions.

SEVERAL efforts have been made to bring about the amalgamation of the two societies which undertake the duties of medical defence, but in each case nothing has come of the proceedings. The failure of the last attempt, however, rather tends to show that so far as the Medical Defence Union is concerned, the amalgamation will never be carried out. The London Counties Medical Protection Society wrote in August last suggesting that an amalgamation should take place, and the reply of the Council of the Union was that they could not accede to the request. No reasons for this decision were given, nor was there any opportunity afforded for further discussing the question. Thus it would seem that the Medical Defence

Union have reasons of their own for maintaining their autonomy, and for refusing to be identified with any other similar organisation. We should, nevertheless, have thought that an amalgamation scheme could have been arranged whereby a mutual adjustment of the affairs of each undertaking could have been satisfactorily effected. Moreover, we cannot quite see the advantage of two societies existing side by side, working for the same ends, and incurring two administrative expenses where one would be amply sufficient. On the other hand the Protection Society is apparently in a very flourishing condition, both as regards finances and membership, and is, therefore, quite able to continue to fulfil its mission independently of its sister organisation.

The Death of an Officer of the Royal Army Medical Corps on the Field of Battle.

WE regret to say that the official list of the killed and wounded published in the press on the 3rd inst. contained the name of Major Edward G. Grey, of the Royal Army Medical Corps. Thus, doubtless, while attending to the wounded on the field of battle, he was shot by the enemy. This sad incident again forcibly recalls the risks run by our non-combatant *confères* in the discharge of their duties, and it emphasises the little-mindedness of those who make a point of taunting the officers of the Army Medical Corps with the fact that they do not belong to the combatant branch of the Service. It was the Duke of Cambridge who described Sir George Robertson, the defender of Chitral, as "a brave civilian." A great deal of notice was taken of this sneer at the time, and it is never likely to be forgotten. Such repeated exhibitions of official bad taste and jealousy are answerable for the medically undermanned condition of the Army at the present time. It was pointed out last week that the Medical service of the Army is in need of nearly 500 officers in order to place it upon a proper footing as to efficiency. If this be the real state of affairs, it is an astounding revelation of what the trifling with the Medical Department by the War Office has led to. There is nothing which can compel young medical men to join the Army, and until the War Office make up their minds to treat the Department properly, the Army will have to do without medical officers.

Anti-Streptococcal Serum in Puerperal Septicæmia.

THE value of the anti-streptococcal serum in modifying the course of puerperal septicæmia must still be regarded as a moot question in spite of the very large number of observations of its use already recorded. Judging from the recent discussion on the subject at the Obstetrical Society of London, the most then can be said of it is that the injections have appeared to exert a marked effect in certain cases, but *per contra*, at least, an equal proportion of cases have proved absolutely refractory thereto. It is suggested, of course, that it is efficacious only in cases of pure streptococcal infection, and unfortunately, neither clinically or bacteriologically, are we in a

position to state what proportion of cases of puerperal septicæmia are due to pure, and what to, mixed infections. Unless the presence of the streptococcus has been formally established the use of the serum is, to say the least of it, empirical but, on the other hand, if we are to await the results of careful bacteriological examination before proceeding to treatment the chances of a successful intervention must necessarily be vastly diminished. The peculiar difficulties in the way of trustworthy bacteriological examination in these cases are such that if we are to wait until the question has been settled we may have to wait a long time. The treatment is on its trial, but the consensus of opinion appeared to be decidedly in favour of continuing its experimental use. It would perhaps be too much to hope for the production of a really efficacious serum until the bacteriology of the various forms of septicæmia has been placed on a sound scientific basis, and for this much further study will be necessary.

The Employment of Civilian Surgeons in the War.

It is stated that some resentment is being expressed by certain officers of the Royal Army Medical Corps at the employment of a large body of civilian practitioners with the force in South Africa, and the editor adds that his sympathy is with the retired medical officers liable to further service whose services are not being utilised in the emergency. However, our contemporary assumes that the War Office want men for the most part who are young and strong, or men who have exceptional qualifications to recommend them. This is probably the case, inasmuch as the sixty or so surgeons whom the Government have already despatched to the Cape are, in the majority of instances, young qualified men who have recently held the post of house-physician or house-surgeon at some large hospital. Undoubtedly these are just the kind of men who would be most calculated to meet the requirements of the position—strong and active in mind and body; and, moreover, equipped with the knowledge of all the newest methods of surgical treatment, resourceful, self-reliant, and eager, above all things, to practise their newly-acquired knowledge—we do not doubt for a moment that the Government have done well to avail themselves of such readily-acquired and efficient aid.

Hepatic Abnormalities in Infants and Children.

THE liver is not an organ in which pathological changes are expected to be met with in infants and children, and yet, judging from some observations upon the subject brought before the American Pediatric Society by Dr. R. G. Freeman, of New York, changes of the kind are not infrequent. Special note was made of the condition of the liver in 500 cases of children dying in the New York Foundling Hospital, and it was found that that in about 41 per cent. of all these the organ was fatty. This condition was

most often present in connection with acute meningitis, gastro-intestinal disorders, measles, and diphtheria, while it was rarely associated with chronic wasting diseases, such as marasmus, malnutrition, rachitis, and syphilis. Again, there was nothing to show that the fatty condition of the liver depended at all upon the nutrition of the child. Another point brought out by the inquiry was that cirrhosis and lardaceous disease of the liver were extremely rare in childhood. These observations are of much interest, and will have to be borne in mind by the authors of text-books, whose teaching upon the subject has hitherto not been in accordance with the facts.

A Congress of Spiritualists.

THE Paris Universal Exhibition of next year—if no international contretemps interferes with its celebration—is to be “honoured” by a congress of spiritualists. That is to say, the opportunity of the great gathering will be taken by the spiritualistic community to hold a conference in order to discuss vital matters concerning their faith. There appears to be two schools of spiritualists, one which maintains that men have successive lives on earth—rather hard on those who have found that one life was enough—and the other that holds that their successive lives run their appointed span in other worlds. Of course this metempsychosical question must be a very important one to spiritualists; on the other hand, there is no reason for supposing that it affords the least interest to anyone else. As long, therefore, as the spiritualists do not come to blows when discussing this question in their congress, probably no one will interfere with them, not even the shades of Blavatsky or the Mahatmas of India. Meanwhile, as a preliminary measure to their proceedings, the spiritualists might inform the world as to the chance of the exhibition ever taking place.

Ships' Medicine Chests.

No doubt a report on the condition of the indispensable medicine chests carried by cargo and other non-passenger vessels would prove interesting reading. We have it on very good authority that they leave much to be desired from a pharmaceutical point of view, but whether the crew are any the worse off by reason of the inability of the captains to administer medicines, is a debatable question. One can understand the necessity for surgical dressing because, even if clumsily applied, they answer to some extent the purpose for which they are intended, viz., protection of wounded surfaces. The same remark applies to splints and bandages which secure more or less immobility in the event of fractures, and tend to relieve the victim's sufferings. When, however, we consider the likelihood of any good resulting from the haphazard administration of medicaments by the captain's untutored hands we feel compelled to make certain reservations. The captain may doubtless be trusted to administer purgative medicines if put up in suitable doses, and he will not incur much responsibility by giving diarrhoea mixture

ipecacuanha wine, or syrup of ginger. Even the administration of quinine might not prove beyond his capacity, but there we must draw the line, for we cannot regard with equanimity the prospect of his administering morphia, or mercury, or even pilocarpine for the purpose of making the hair grow or otherwise. Marine therapeutics, therefore, in the absence of a qualified adviser, must necessarily be a simple matter, so simple, indeed, that it hardly seems worth while to oblige vessels to carry a medicine chest at all. On the whole, we should, perhaps, better serve the interests of those who go down to the sea in ships if we limited the therapeutical armamentarium to the two or three simple remedies aforesaid, and under these circumstances we think it may possibly be unnecessary to urge the Board of Trade to take steps to verify the contents of the chests at present in use.

Dublin Insalubrity.

THE records of the mortality in the second city of the Empire for the past four months is positively appalling. The death rate for the quarter, from all causes, was 30·4 per 1,000 of the population, or 7·3 over average, and the week ending October 28th recorded the largely increased mortality of 36·4, which compares with 20·8 for London and 18·5 for Edinburgh. It is, however, in the deaths from zymotics that the most alarming increase is manifested. From these diseases the deaths numbered 773, being no less than 527 over previous quarter, and 422 over average, the rate being 8·8 per 1,000. This terrible slaughter was the result, chiefly, of epidemics of measles and diarrhoea. The deaths from the latter ailment during the quarter were 372, being more than double the average (180). From measles the deaths numbered 189—as against the ten years' average of 15—and the prevalence appears to be increasing by leaps and bounds, the admission to hospital for measles having advanced within a fortnight from 43 to 60. It is in view of this appalling state of things that the Hospitals, the Poor-Law Guardians, and the Corporation are engaged in recriminations and discussions as to whether something or nothing shall be done to provide for the infected sick, the existing accommodation having collapsed under the strain.

The Army Medical Service and Its Critics.

WE note that two individuals, Sir Arthur Grant and Sir Claude de Crespigny, whose utterances are, if not important, at least amusing, have favoured the public with unmeasured abuse of the Army Medical Corps, both such utterances being after hearty public luncheons, and one of them after a phenomenal feast of oysters at Colchester. Our military *confrères* must accept the rebukes of these orators “with bated breath and whispering humbleness,” considering that the intellectual qualities of both are guaranteed by the fact that they are bucolic baronets. They have also been at some time soldiers *longo intervallo*, the first-named being a captain of yeomanry and the other a naval man who is also a captain of the Limerick Militia. The *Army Gazette*, by a

reprehensible omission, does not state the war services of either of them. It seems to us that the most effective luncheon critics are those who combine total ignorance of the subject and bitter prejudice begotten of that ignorance, and therefore the Royal Army Medical Corps must rest content under the censure of these speakers. Major-General Abadie, who presided at the oyster lunch, cannot be so excused, considering that he sat complacently to hear his brother officers abused in terms alike false and vulgar. But what is to be expected when it is recollected that he is obliged to keep himself in the fashion of depreciation set by the Commander-in-Chief and Sir Redvers Buller.

Reciprocity of Medical Practice with Italy.

WE are informed that the Italian Prime Minister has promised a deputation of Italian practitioners that he will introduce in the session of his Parliament which is to open next week a Bill to prohibit practice, even among their own countrymen, by medical men who do not hold Italian degrees unless the country of their qualification concedes reciprocal rights of practice to Italian graduates. This is a very serious matter, inasmuch as the medical care of English and American visitors throughout the Riviera and other health resorts is almost entirely in the hands of English practitioners. It is also a question difficult to settle, because the law of practice is different in the two countries. In Great Britain an Italian can practise as every other non-registered person can, as he pleases, but this is not much of a concession considering that every unregistered person can do the same. He can, also, have his qualification entered in the register if he has acquired a British medical qualification, but not otherwise. In Italy, on the contrary, a British registree cannot *practise* without the tolerance of the Government, but many have done so by virtue of that tolerance. Thus it appears that Great Britain cannot conform to the wishes of Italy, unless it admits all Italian medical degrees to the register, an impossible alternative. The dispute, therefore, seems to be impossible of adjustment, but the Italians ought, before proceeding to disfranchise the British graduates, to recollect that, if they do so, they will assuredly cut off from their health resorts the numerous and liberal cash-paying English speaking visitors who now frequent these places. For such customers an Italian general practitioner is an absolute impossibility.

WE regret to have to announce the death of Mr. W. C. Arnison, Professor of Surgery in the University of Durham, who died on Saturday last at his residence at Newcastle-on-Tyne, from pleuro-pneumonia. Mr. Arnison succeeded Dr. Heath in the professorship, and was president of the British Medical Association some years since when it met at Newcastle. Mr. Arnison rejoiced in a high reputation as a surgeon, and though of a retiring disposition his loss is mourned by a large circle of friends.

FORTY officers and men belonging to the Royal Army Medical Corps are leaving Plymouth to-day for the seat of war.

PERSONAL.

DR. THEODORE WILLIAMS has presented £1,000 to the Endowment Fund of the Royal College of Physicians London.

LORD DUFFERIN was elected Lord Rector of the University of Edinburgh on Saturday last by a large majority over his opponent, Mr. Asquith.

MR. FRANK PARISH, Mayor of Worthing, has been appointed to the Commission of the Peace for the county of Sussex by the Lord Chancellor.

DEPUTY Inspector-General of Hospitals and Fleets, Henry Harkan, R.N., has been awarded the Greenwich Hospital pension of £50 a year, rendered vacant by the death of Fleet Surgeon Robert Willcox, R.N.

WE regret to learn that Dr. Charles Bent Ball, Surgeon to Sir Patrick Dun's Hospital, is laid up with an enteric attack. His progress is reported to be quite satisfactory, and it is hoped that he will soon be able to resume practice.

RESULTING from an inquiry by the Local Government Board into the alleged misconduct of Dr. Burns, Poor-law Medical Officer of Sunderland, that gentleman was requested to resign his office last week. He completed his deposition by suicide with prussic acid.

THE "call of duty" to the Transvaal Government has just been responded to by Dr. Neethling, a native of that country, by resigning the office of house surgeon to the Bradford Royal Infirmary, to which he had recently been appointed, for medical service during the war.

MR. ROBERT D. JOYCE has been appointed Assistant Ophthalmic Surgeon to the Richmond, Whitworth, and Hardwicke Hospitals, Dublin. Mr. Joyce had a distinguished career in the Catholic University, and served as house-surgeon of the National Eye and Ear Hospital, Dublin.

SIR WM. MACCORMAC and Mr. Makins, of St. Thomas's Hospital, were the subjects of an enthusiastic send off to the war on Saturday by about 300 medical students; Mr. Makins was shouldered to his carriage. The Director-General of the Army Medical Department, Surgeon-General Reade, Dr. Ord of St. Thomas's Hospital, Mr. Butlin of St. Bartholomew's, Dr. Frank of Nice, and Mr. R. O'Callaghan were among the members of the profession to bid them adieu on the platform.

THE honorary Freedom and Livery of the Salters' Company will be bestowed on Sir William MacCormac on his return from the South African campaign, as a mark of appreciation of his conduct in placing his services at the command of Her Majesty's Government. Among other members of the profession on whom this distinction has been conferred, were the late Baronets Sir William Fergusson, Sir William Gull, and Sir William Savory.

Dr. W. J. ANSORGE, of the Colonial Medical Service, is on his way to Old Calabar to take up his post as District Medical Officer in the Niger Coast Protectorate. Dr. Anson is a traveller *hors concours*, and is, moreover, an enthusiastic student of natural history, to which he has made numerous contributions.

A MEETING of the members of the profession practising in Limerick and its vicinity was held on Saturday last for the purpose of setting on foot a movement for presenting an address to Dr. Thomas Myles, Vice-President of the Irish College of Surgeons, on the occasion of his elevation to the Presidency next June. Dr. Myles is a native of Limerick, and there was a large attendance of his *confrères* on the occasion. The chair was occupied by Dr. O'Shaughnessy, D.L., who expressed his high appreciation of Dr. Myles. The necessary resolutions having been passed the meeting adjourned.

Scotland.

[FROM OUR SPECIAL CORRESPONDENT.]

RECTORIAL ELECTIONS.—At regular intervals the students of the Scottish Universities are granted a certain amount of license towards the exhibition of animal spirits in a physical manner, in direct association with their academic environment. These occasions arise as the time for the election of new Lord Rectors of the Universities comes round. Pease meal and explosive hand-grenades of parti-coloured ochre play a prominent part in what is really a mimic political fight. Edinburgh students have just passed through such a saturnalia; those of Unionist tendencies—imperialistic they called them—supporting Lord Dufferin; their opponents the Right Hon. Mr. Asquith. Lord Dufferin was elected by a majority of 257 in a poll of 1,629 over Mr. Asquith; friends and foes of the successful candidate participating later in the day in a fancy dress torch-light procession through the main streets of the city. The excitement of the contest was marred by one regrettable incident; for, during what can only be characterised as a free rough-and-tumble fight in the physiological class-room, one of the combatants fell and broke his leg. Although the withdrawal of Sir Edward Grey from the lists at Aberdeen left Lord Strathcona and Mount Royal the unopposed candidate, the proceedings of election were marked by an organised nomination fight, followed by a combined attack on the citizens who had assembled to watch the proceedings, and ended by a baton charge by the police, the arrest of several students, and the wounding of others.

Manchester.

[FROM OUR OWN CORRESPONDENT.]

ANOTHER ABORTIVE ATTEMPT TO SETTLE THE ROYAL INFIRMARY QUESTION.—The long extended conference between the Special Committee of the City Council and representatives of the Infirmary Board, with a view to the purchase of the present site and the provision of a new hospital, has come to nought. The Special Committee proposed the payment of £350,000 for the site and buildings and the erection of an emergency hospital and out-patients' department in a central position at a cost of £50. The Infirmary authorities suggested the acceptance of the £350,000, on the condition that the central emergency hospital should be built on the present site, and that the Corporation should not cover more than 4,200 sq. yds. of the remaining area. The representatives

of the Corporation have now passed a resolution to the effect that negotiations are at an end so far as they are concerned. It, therefore, remains for the Infirmary Board to arrange its own scheme for representation to the trustees of the institution. After so much waste of time and energy, it is to be hoped that Manchester will at last take effectual steps for the immediate establishment of a thoroughly modern hospital.

PATHOLOGICAL SOCIETY.—This, the largest of the Manchester Medical Societies, has just issued its annual report. It was originally established in 1885. At the present time it has a membership of 417. It has also 7 Honorary Members, gentlemen distinguished in Medicine, and the allied sciences. The Society has completed arrangements, whereby its Members may have Examinations of Morbid Products conducted for them at the Owens College.

PURE MILK SUPPLY.—Thanks to the scientifically-directed energy and public spirit of a number of leading citizens, a company has been formed for the supply of non-tuberculous and absolutely pure milk, butter and cheese. Elaborate buildings have been erected and fitted with the most approved apparatus. The farms supplying the milk are under rigorous inspection, and thorough precautions are taken for insuring a perfect collection, storage and delivery of the milk to the individual consumer. Such prophylactic measures deserve support, and must eventually influence for good the, at present, unsanitary and negligent procedures of the average dairyman.

SMALL-POX HOSPITAL.—Considerable opposition is being raised to the proposal of the Corporation to erect a new small-pox hospital at Carrington Moss, at an estimated cost of £60,000. It is said that within the last four years less than a score cases of variola have occurred. In the three years, 1892-3-4, 993 cases had to be dealt with. It is contended that the present Hospital is quite adequate, and that the new one, if erected on the proposed site some dozen miles distant and situated in a water-logged, low-lying district, would be both inconvenient and unhealthy.

VICTORIA UNIVERSITY.—Students will be interested to learn who are the new external examiners in the Faculty of Medicine. The following have just been appointed:—External examiner in physiology, J. G. M'Kendrick, M.D., F.R.S., professor of physiology, Glasgow University; external examiner in forensic medicine, A. P. Luff M.D., lecturer in St. Mary's Hospital, London; external examiner in public health, Arthur Ransome, M.D., F.R.S.; external examiner in surgery, A. Ernest Maylard, M.B.; external examiner in medicine, David Bridge Lees, B.Sc., M.D., lecturer in St. Mary's Hospital, London.

We do not hold ourselves responsible for the opinions of our correspondents.

REVOCATION OF THE MUZZLING ORDER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR—The muzzling order has been withdrawn in London and Lancashire, and, as you correctly remark, only in South Wales and in Ireland is it now in force. This withdrawal of the order is stated to be the result of the cessation of rabies in England, but before we can acknowledge the sufficiency of this reason we must admit the prevalence of hydrophobia therein, which I for one do not and never have done, because the method of investigation, or the evidence upon which the Government has acted in deciding the question has never been ascertained. We know that in Ireland, where the order still remains in force, every sick cur which a peasant kills by a blow of a stone, or a policeman batons to death, is gazetted as rabid, and, in not one case out of fifty, is any reliable means of confirmation of the diagnosis resorted to. Unless some more effective method has been adopted in England, I am prepared to believe that hydrophobia in either man or beast is, to a great extent

imaginary, that a muzzling order was never required at all, and that the cessation of a disease which existed only to a very inappreciable extent does no special credit to such order, and which, in fact, might have been avoided altogether if instructions had been promulgated that all cases should be investigated by an expert before they were reported as cases of rabies. I note that the Government prides itself upon the fact that in the London district alone, it slaughtered 24,000 dogs in five months, and I offer no complaint of its having done so, inasmuch as it is necessarily obviously to combat, in some way, the continually growing excess of stray curs, and, by so doing, the risk of hydrophobia must be necessarily diminished. But all this slaughter neither proves the extinction of that disease, nor justifies the statements as to its prevalence. I trust, however, that Mr. Walter Long, M.P., will by this time, be persuaded that it is a mistake to introduce legislation which cannot be warranted by facts and proofs.

I am, Sir, yours truly,

A SCEPTIC.

THE INDIAN MEDICAL SERVICE AND THE ROYAL ARMY MEDICAL CORPS

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you permit me to offer a reply to the letter signed T. C. D., which appeared in your issue of November 1st. I consider that, apart from its personally offensive nature, the lucubration referred to is essentially a foolish one, as the writer gives away the greater part of his case by stating that he is a civilian (which, by the way, seems scarcely correct, but this is a digression) (a) and, as such, has no sympathy with the spirit of militarism in the R.A.M.C. If the civilian status of the writer is admitted, he has no right to criticise the views relating to military rank and position, which are held by officers of H.M. Army serving under conditions with which he can have no practical acquaintance whatever. His criticism therefore, so far as it concerns a spirit of militarism, is simply a gratuitous impertinence; it re-echoes also a common mistake as to the essential nature of the phrase "military duty." There is no greater error nor one more productive of mischievous consequences, as far as the status of medical officers of the army is concerned, than to regard as military duties, only such duties, as are of a purely combative nature, such as field firing, bayonet exercise, &c. All duties in the Army are designed for the maintenance of efficiency in H.M. forces and by inference for the destruction of H.M. enemies. If the above statement is correct the care and treatment of the sick in military hospitals will possess something besides a professional interest; in other words, the successful performance of professional work will be attended by a feeling of justifiable pride at the efficient performance of military duty. The latter, it is presumed, is a matter in which your "civil" correspondent will take no particular interest. There is also another point in this connection which is worthy of attention. Warfare is no longer what our American brethren would denominate "a brain busting match" with battle-axes, but is an art demanding for its successful accomplishment the application of many sciences, and, among these, the sciences of medicine, surgery, and sanitation, and it is only reasonable that men who have been specially trained in the purely military application of the sciences which they profess, and who are called upon to face the risks and hardships of war, should be rightly regarded as "soldiers," should take pride in an honourable title, and should be animated with that spirit of militarism which your correspondent considers himself called upon to decry. There is no inconsistency between professional efficiency and soldier-like zeal, and among medical officers he is the best soldier who places the highest professional gifts at the service of his country.

It is impossible at present to be sure whether the best professional men enter the I.M.S. or the R.A.M.C., and the *ex parte* statement of T. C. D. proves nothing.

(a) I presume that the writer is an officer of the Indian Medical Service, and he uses apparently the word "civil" in the same sense as "civilian."

The question of enteric fever in India is too large for present discussion, except in so far as to protest against the inference which must be drawn from the earlier remarks in the letter at present referred to. These remarks must, however, from their nature go some way towards discounting the value of the writer's remaining statements.

It would be interesting to know how far an extremely offensive and equally foolish letter will be appreciated by the author's brother officers in a distinguished and honourable service.

I am, Sir, yours truly,
R.A.M.C.

Laboratory Notes.

SOME NEW SOLOIDS.

AMONG recent additions to the apparently inexhaustible list of ready-made formulæ prepared in "soloid" and "tabloid" form by Messrs. Burroughs, Wellcome and Co., we note with satisfaction the soloids (1) of *Lead Subacetate*, and (2) of *Lead Subacetate and Opium*. The convenience of being able at a minute's notice to prepare these commonly-used applications will doubtless be adequately appreciated.

Equally convenient for immediate use in urgent cases are the soloids (1) of *Sodium Chloride*; (2) of *Sodium Chloride Compound*; and (3) of *Sodium Chloride and Sodium Sulphate*. In preparing saline solutions of the proper strength for intravenous injections these will be found invaluable.

NEW TABLOIDS.

Holocaine Hydrochloride is a substitute for cocaine in ophthalmic practice. The anaesthesia which it produces is claimed to be more rapid and complete than that produced by cocaine, and being more superficial it is specially indicated in preparing for the removal of foreign bodies and in operations on the conjunctiva. Unlike cocaine, its effects are produced even in presence of inflammation. It is devoid of any action on the pupil and does not modify accommodation or ocular tension. The tabloids of *Holocaine* contain 1.50 grains each.

The two-grain tabloids of extract of *Cascara Sagrada* not having been found to allow sufficient margin for the idiosyncrasy of some patients and the acquired tolerance of others, one grain and three-grain tabloids are now prepared. The larger dose may be taken to overcome existing constipation, and then the smaller dose will serve to maintain intestinal regularity. These tabloids can be had either plain or sugar-coated.

Lastly, we are introduced to the five-grain tabloids of *Guaiacol Camphorate*, a convenient means of exhibiting this base in the treatment of tuberculosis, chronic bronchitis, &c.

EFFERVESCENT TABLOID SERIES.

MESSRS. BURROUGHS, WELLCOME and Co., have submitted to us various samples of the new series of effervescent tabloids. The series comprises tabloids of artificial Carlsbad salt, of artificial Vichy salt, of citrate of caffeine, bitartrate of lithium, citrate of lithium, citrate and sulphate of sodium, &c. The effervescent form which is thus rendered readily available will certainly be greatly appreciated. Less bulky than the ordinary effervescent products, these tabloids secure greater accuracy of dosage, and, in general, greater facility of administration. It is sufficient to place one or more of the tabloids in a suitable quantity of water, and in a short time we have a clear solution, refreshing to the palate, and well adapted to secure the maximum and immediate effects of the active ingredient or ingredients. The effervescent magnesium sulphate compound tabloid will be found a very agreeable and effectual laxative at all seasons.

Among the recent additions to the list of products issued by Messrs. Burroughs, Wellcome and Co., we may note the tabloids of Bismuth and Dover's powder as 2.5 grains, the tabloids of *Krameria* and *Cocaine*, and a new series of tabloids corresponding in dosage and

active ingredients to the B. P. pills, among others aloes and iron, compound colocynth, aloes and myrrh, blue pill, colocynth and hyoscyamus, lead and opium, ipecacuanha, and squills, &c. It is unnecessary to insist on the uses to which these various tabloids may be applied, as they are obvious.

SOLID MICROSCOPIC STAINS.

THE introduction of stains for microscopic work in "Soloid" form is a new departure which needs no justification in view of the tendency of aniline dyes to undergo decomposition—a fertile source of disappointment and wasted labour in the laboratory. The series comprises (1) Gentian violet, (2) Methylene blue, (3) Eosin, (4) Bismarck brown, and (5) Fuchsin, and directions for their use are given in an accompanying leaflet. These "Soloids" will specially prove a boon to travelling investigators and those whose laboratory work is discontinuous, inasmuch as by their aid the requisite solutions can be prepared as required, accurately dosed, and with a minimum of trouble.

Literature.

ROTH ON LATERAL CURVATURE (a).

TEN years have passed since Mr. Roth brought out his first edition of this work, an edition that might fairly be looked on as an enlarged edition of his excellent article on the subject in Mr. C. Heath's "Dictionary of Practical Surgery," in 1886.

We mention these facts to show that from its inception Mr. Roth wrote as a practical surgeon, one who in his own experience has felt the inadequacy of the mechanical cages, metallic and poroplastic, which instrument makers delight to see, and which remain on the poor patient as instruments of torture and nothing more. Again and again we have been pained by seeing poor children tormented and weighed down with a poro-plastic or other cage that but added to their sufferings and promoted that muscular degeneration which intensified their agony and cut off the last hope of health.

The conservatism of the medical profession is well marked by our adherence to existing methods of treatment of spinal curvature. Apparatus came to be adopted, and as a result every form of spinal curvature was deemed a fitting case for the apparatus without any thought being given to the cause of the curvature and to preventive measures.

If Mr. Roth's book has any value greater than another in surgery it is that it calls on the reader to think, to ponder on the causes of the deformity, that the deformity may be prevented, and when it has been established it may be got rid of.

The success of the treatment is well shown by the series of 1,201 (twelve hundred) cases found in the appendix, a number that justifies the author in hoping that his book will ultimately banish the mechanical apparatus, metallic and poroplastic, to their proper place, the instrumental museum. The book is a valuable and original contribution to medical literature, of lasting value as the work of a practical surgeon and withal profound thinker.

MITCHELL BRUCE'S THERAPEUTICS. (b)

THE fact that the latest edition of this well-known work registers its thirty-eighth thousand is sufficient to attest its merits and its popularity. At the risk of appearing somewhat hypercritical, however, we venture to draw attention to a few points the alteration of which would in our opinion enhance the value of this work. For instance, there is no mention of a "dusting powder" in the index, and we have failed to

(a) "The Treatment of Lateral Curvature of the Spine, with Appendix, giving an analysis of 1,000 consecutive cases treated by posture and exercises exclusively (without mechanical supports)." By Bernard Roth, F.R.C.S. Second edition, London: H. K. Lewis. 1898.

(b) "Materia Medica and Therapeutics." By J. Mitchell Bruce, M.D., Physician and Lecturer, Charing Cross Hospital, &c. London and New York: Cassell and Co. 1899.

find any passage dealing with the varied uses of that commonly used method of applying soothing, astringent, drying, and antiseptic remedies to the skin. Indeed, that organ appears to have been not a little neglected, for we find no mention of the therapeutic action of light, both solar and electrical, and of the focus-tube used in X-ray photography. Even if these actions are to be looked upon as in their tentative stage so far as practice is concerned they are nevertheless worthy of mention in a book of this importance and width of range. The indelible staining due to the prolonged use of silver salts is dismissed with a few words, and no mention made of the anatomical elements in which the deposit occurs. The important practical point of lead deposits, leading to lead "opacities" in the cornea, is not alluded to. Nor do we find any mention of super-heated air baths, such as Tallerman's, under the heading of "Baths and Allied Measures," which deals only with Turkish and compressed air under the sub-section "Air Baths." This omission in the year 1899 mars the symmetry of a standard work on therapeutics, considering that this method of treatment has been before the profession for several years past. Turning to the many alterations, additions and omissions made in the British Pharmacopoeia of 1898 we find, so far as we have tested them, they are accurately recorded. *Emplastrum Belladonnae*, however, given on page 349 as containing 5 per cent. of alkaloids should be obviously 0.5 per cent. While offering these few criticisms, it must not be thought for a moment that we are detracting from the general excellence of the book, which deservedly holds a foremost place upon the shelves of the student and of the practitioner. Both author and publishers are to be congratulated on the perennial vigour of their production.

REID ON PRACTICAL SANITATION. (a)

THE appearance of the fifth edition of this excellent handbook is marked with additional interest from the fact that the book has been completely revised, and to a great extent rewritten. The chief feature in this work, if one may generalise, is its practical nature, which stamps every page of the contents with a character that cannot be derived from study-chair cogitations. An excellent illustration of this tendency is the chapter on plumber's work, which gives just the sort of information that is wanted in sanitary administration. Most householders of experience will agree with the general proposition that "all cheap plumbing is bad, and good plumbing must be paid for." Unfortunately, the length of the tradesmen's bill is not, in this instance, an invariable guarantee that an adequate amount of good work has been performed in return for the money payment. Although this book was written in the first place for the use of sanitary inspectors, it is of great value to medical officers of health and to students of sanitary subjects. Nor, should we imagine, does it fail to find a large number of readers among architects and builders. The subject of the closure of schools has hardly been given the prominence it deserves. Not only is the agency in question undoubtedly answerable for the enormous increase in diphtheria of late years, but is concerned in other conditions, such as measles, whooping-cough, and quite likely diarrhoea. The book ends with an excellent abstract of the principal Acts relating to Public Health.

WHITELEGGE'S PUBLIC HEALTH. (b)

THIS volume ushers in the seventh thousand of Dr. Whitelegge's well-known work. He has incorporated in the text the more important recent developments in many branches of hygiene. The Vaccination Act of 1898 will be ever memorable in the history of preventive medicine. As the author remarks, it has "introduced a momentous change in the administration of a department which has rendered incalculable benefit to the

(a) "Practical Sanitation." By George Reid, M.D. Fifth Edition, London: Griffin and Co. 1899.

(b) "Hygiene and Public Health." By B. Arthur Whitelegge, M.D. London: Cassell and Co. 1899. Seventh Thousand.

community, in a form which lends itself to statistical demonstration." A summary of the results of vaccination is given, together with many tables and figures, whereby the investigator is furnished with a veritable mine of facts on which to found his conclusions. The standard nature of this work need not be enlarged upon. The reader will find a good illustration of the author's power of sifting out salient points and of setting them forth in a clear condensed form if he turns to the section dealing with the all-important subject of school infection. A careful perusal of the pages devoted to this point will place him in possession of a key to all that is known about it. There is no need to say that this book should be in the hands of all students of hygiene, because that advice is already anticipated. It should, however, also be on the bookshelf of every well-educated medical practitioner, for the subject is one with which every branch of medical practice is at one time or another intimately concerned.

NEW BOOKS AND NEW EDITIONS.

The following have been received for Review since the publication of our last monthly list:—

- BAILLIÈRE, TINDALL AND COX (London and Paris).
 A Manual of Surgery for Students and Practitioners. By William Rose, M.B., B.S., Lond. F.R.C.S., and Albert Carless, M.S., Lond., F.R.C.S. Second Edition. Pp. 1190. Price 21s.
 An Introduction to Diseases of the Nervous System. By H. Campbell Thomson, M.D., M.R.C.P., Lond. Pp. 124. Price 4s.
 Difficult Digestion due to Displacements. By A. Symons Eccles, M.B., M.R.C.S. Pp. 138. Price 4s.
 BALE, SONS and DANIELSON, Ltd. (London).
 On the Prevention of Eye Accidents Occurring in Trades. By Simeon Snell, F.R.C.S. Ed. Pp. 32. Price 1s. net.
 J. AND A. CHURCHILL (London).
 Open-Air Treatment of Consumption. By Jane Walker, L.R.C.P., M.R.C.S., M.D. (Brux). Pp. 15. Price 1s.
 Year-book of Pharmacy, from July 1st, 1898, to June 30th, 1899, with the Transactions of the Pharmaceutical Conference held at Plymouth. Pp. 548.
 H. J. GLAISHER (London).
 Cancer. By Thos. Wm. Nunn, F.R.C.S. Pp. 90. Price 2s.
 P. S. KING AND SON (London).
 Archives of Neurology from the Pathological Laboratory of the London County Asylum. Edited by F. W. Mott, F.R.S., M.D., F.R.C.P., Lond. Pp. 552. Price 15s.
 HENRI LAMERTIN (Bruxelles).
 L'Année Chirurgicale. Par le Docteur A. Depage. Première Année. Pp. 1,970.
 H. K. LEWIS (London).
 A Contribution to the Surgery of Fractures and Dislocations of the Upper Extremity. By J. E. Platt, M.S., F.R.C.S. Pp. 228. Price 10s.
 Rough Notes on Remedies. By Wm. Murray, M.D., F.R.C.P. Lond. Third Edition. Pp. 142. Price 3s. 6d.
 Text-Book of Ophthalmology. By Dr. Ernest Fuhs. Translated by A. Duane, M.D. Pp. 876. Price 21s.
 The Anatomy of the Central Nervous System in Man, and Vertebrates in General. By Professor Ludwig Edinger, M.D. Translated by Drs. W. S. Hall, P. L. Holland, and Edward P. Carlton. Pp. 457. Price 15s. net.
 E AND S. LIVINGSTONE (Edinburgh).
 Materia Medica. Part I. Catechism Series. (Author's name not given). Pp. 72. Price 1s.
 LONGMANS, GREEN AND CO. (London and Bombay).
 Surgery, a Treatise for Students and Practitioners. By Thos. P. Pick, Consulting Surgeon to St. George's Hospital. Pp. 1176. Price 25s.
 MACMILLAN AND CO. (London).
 Differential Diagnosis with Clinical Memoranda. By Fred. J. Smith, M.D. Oxon., F.R.C.P. Lond. Pp. 352. Price 7s. 6d. net.
 Transactions of the Jenner Institute of Preventive Medicine. Second Series. Pp. 253.
 JAMES MACLEHOSE AND SONS (Glasgow).
 Raynaud's Disease; its History, Causes, and Treatment. By Thos. K. Munro, M.A., M.D. Pp. 250.
 OLIVER and BOYD (Edinburgh).
 A Manual of Modern Gastric Methods. By A. Lockhart Gillespie, M.D., F.R.C.P., F.R.S. Ed., with a Chapter on Mechanical Methods in Young Children. By John Thomson, M.D., F.R.C.S. Ed. Pp. 175.
 THE UNIVERSITY PRESS, LIMITED (Watford).
 The Pathology of Emotions. By Ch. Féré, M.D., Paris. Translated by Robert Park, M.D. Pp. 542. Price 15s.

The Universal Illusion of Free Will and Criminal Responsibility. By A. Hamon. Pp. 138. Price 3s. 6d. net.
 Darwin on Trial at the Old Bailey. By Democritus. Pp. 107. Price 2s.

Medical News.

The Medicine Sickness and Accident Society

The usual monthly meeting of the executive committee of the Medicine Sickness Annuity and Life Assurance Society was held at 429, Strand, London, W.C., on 27th ult. There were present Dr. de Havilland Hall in the chair, Dr. J. B. Ball, Dr. J. W. Hunt, Mr. F. S. Edwards, Dr. W. Knowsley Sibley, Dr. M. Greenwood, Dr. Walter Smith, and Dr. Alfred S. Gubb. The sickness experience of the Society during the summer months has been much lighter than that of the early spring and is well under the amount expected. The list of those members who are permanently disabled from professional work still grows and the amount of sickness benefit paid to them is one of the most important of the Society's disbursements. During August and September a cash bonus was paid to the sickness benefit members of over three years' standing at December 31st last. The total amount so paid was a little over £5,000, and a few cheques are still outstanding. The account will be closed at the end of this month, and the balance transferred to the Sickness Benefit Fund. Prospectuses and all particulars on application to Mr. F. Addiscott, Sec. Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

The Infectious Disease (Notification) Extension Act, 1899.

A CIRCULAR has been addressed from the Local Government Board to local authorities for whose districts the Infectious Disease (Notification) Act, 1899, has not been adopted. The attention of the local authorities is drawn to the effect which the Infectious Disease (Notification) Extension Act, 1899, will have in extending the operation of the Infectious Disease (Notification) Act, 1889. At present the provisions of the Act of 1889 are in force in those urban, rural, or port sanitary districts where that Act has been adopted by local authorities in the prescribed manner. The effect, however, of section 1 (1) of the new Act, which comes into operation on January 1st, 1900, will be to extend as from that date those provisions to every urban, rural, and port sanitary district in England and Wales, whether the principal Act has or has not been previously adopted therein. The circular is accompanied by a memorandum of instruction, to medical officers and a form of certificate.

The Transvaal and the R. A. M. C.

REFERRING to the strain thrown by the outbreak of hostilities in South Africa on the Royal Army Medical Corps, the *Civil and Military Gazette* points out that the strength of the corps is about 20 per cent. lower than what it was thirty or forty years ago, and this notwithstanding an increase of the Army and a great extension of its foreign duties. The present strength is about 840, or 50 below the figure (viz. 890) which the late Sir Thomas Crawford, Director-General of the Army Medical Department, fixed some fifteen years ago as the absolute minimum, and that "dangerously low." The consequence is that at present about 90 officers on the retired list and a good number of civilian practitioners are being employed in the home military districts to discharge duties which should fall to medical officers on the active list. Indeed, matters are so bad that in one military district in England there were lately only seven medical officers on the active list, the proper complement being fixed at 19. There has necessarily been for some time considerable difficulty in granting army medical officers adequate leave; and the strain of a war in South Africa can only serve to augment the difficulties of the authorities. It is urged that the strength of the corps should be raised to 1,000, but since candidates are not forthcoming in sufficient numbers to fulfil the existing vacancies and the concession of military titles has failed to attract young doctors into the army, it is clear that some more practical measures must be adopted. The authorities

have now made two attempts to work the reform of the cheap by ringing the changes on ranks and titles in the somewhat simple belief that sentimental marks of esteem would be accepted in place of practical concessions. Their sanguine expectations have been disappointed, and they must now face the unwelcome fact that the market price must be paid in hard cash, and not in fancy names or meaningless titles. At all events, if the South African trouble develops into a big thing, the demand for army doctors will so far exceed the supply as to convince the War Office that the question cannot be played with any longer.

Royal College of Surgeons in Ireland.

At the opening of the Winter Session the following prizes were awarded:—

Carmichael Scholarship—Miss M. J. Shire, £15. Mayne Scholarship—D. A. Fitzgerald, £15. Gold and Silver Medals in Operative Surgery—C. R. Boyce, gold medal; C. Myles and J. F. Peart (equal) silver medal. Practical Histology—E. Evatt, first prize (£3) and medal; A. Charles, second prize (£1) and certificate. Practical Chemistry—E. C. Byrne and J. R. H. McManus (equal), first prize (2) and medal. Public Health and Forensic Medicine—J. P. Byrne, first prize (£3) and medal; E. Evatt, second prize (£1) and certificate. Materia Medica—J. S. Ashe, first prize (£3) and medal; T. A. Dillon, second prize (£1) and certificate. Practical Pharmacy—Miss J. C. Hargrave, first prize (£3) and medal; W. Ormsby, second prize (£1) and certificate. Biology—J. R. B. Buchanan and Miss J. C. Hargrave (equal), first prize (£2) and medal. Descriptive Anatomy—Junior, J. Cockburn, first prize (£3) and medal; R. G. Allen, second prize (£1) and certificate. Senior, A. Charles, first prize (£3) and medal; T. A. Dillon, second prize (£1) and certificate. Practical Anatomy—First year, R. G. Allen, first prize (£3) and medal; R. W. Burkitt, second prize (£1) and certificate. Second Year, A. Charles, first prize (£3) and medal; C. W. Ewing, second prize (£1) and certificate. Third Year, C. R. Boyce, first prize (£3) and medal; J. F. Peart, second prize (£1) and certificate. Practice of Medicine—J. P. Byrne, first prize (£3) and medal; T. J. Tallon, second prize (£1) and certificate. Surgery—J. S. P. Stewart, first prize (£3) and medal; J. P. Byrne and W. R. Meredith (equal), second prize (£1) and certificate. Midwifery—Mrs. H. L. Hennessy, first prize (£3) and medal; J. S. P. Stewart, second prize (£1) and certificate. Physiology—Miss M. J. Shire, first prize (£3) and medal; A. Charles, second prize (£1) and certificate. Chemistry—T. Keogh, first prize (£3) and medal; G. G. Tabuteau, second prize (£1) and certificate. Pathology—J. F. Peart, first prize (£3) and medal; H. Graff, second prize (£1) and certificate; and Physics—W. Ormsby, first prize (£3) and medal; A. Ellenbogen, second prize (£1) and certificate.

The West London Hospital.

THE annual dinner of the staff of the West London Hospital took place at the Great Central Hotel on Wednesday, October 25th, 1899, Mr. Percy Dunn being in the chair. Out of twenty acceptances, seventeen members of the staff were present. After the usual loyal toasts had been duly honoured, the chairman proposed the toast of the "West London Hospital," in the course of which he referred to the gratifying progress which had been made in the organisation of the post-graduate college in connection with the hospital, and to the benefits that were likely to accrue from the enlargement and improvements now being effected in the out-patient department. Afterwards the *reunion* resolved itself into a committee, in which many matters were discussed relative to the well-being of the hospital, and resolutions passed thereupon. The toast of "The Health of the Chairman," proposed by Mr. Keetley, brought the proceedings to a close.

East-Suburban Medical Protection and Medico-Ethical Society, The West Ham Hospital, Stratford, E.

A GENERAL meeting of the above Society was held at the Town Hall, Stratford, E., on November 7th, at 3.15 p.m., when Mr. C. S. Loch, the Secretary of the

Charity Organisation Society, gave an address and opened a discussion upon "The Use of Medical Charities," the chair was taken by Fred. J. Smith, Esq., M.D., Physician to the London Hospital. The following resolution was carried:—"That this meeting of the East-Suburban . . . Society and other Medical Practitioners is of opinion that as a means of preventing the misuse of medical charities—supported wholly or in part by voluntary contributions—medical men should be elected on the governing and executive bodies of such charities in a proportion of not less than 25 per cent., such representatives to be periodically elected by the medical practitioners in the vicinity, and hereby invite the medical profession as a whole to support this policy. That copies of this resolution be sent to the various medical societies requesting their support; and to the Press." This was proposed by Murtaugh Houghton, Esq.

The Paris International Congress of Medicine, August, 1900.

THE French Executive Committee have issued a notice that every member of the Congress who desires to read a paper at the forthcoming meeting must send the title and an abstract of his paper to the proper sectional secretary on or before May 1st, 1900. To facilitate this proceeding the Executive Committee gives the following list of the secretaries with their addresses:—1. Comparative anatomy: Dr. Auguste Petit, 6, Rue Saint André des Arts; 2. Descriptive anatomy: Dr. Rieffel, 7, Rue de l'Ecole de Médecine; 3. Histology and embryology: Dr. Retterer and Dr. Loisel, 15, Rue de l'Ecole de Médecine; 4. Physiology, with biological physics and chemistry: Dr. Dastre at the Sorbonne; Dr. Gley, 14, Rue Monsieur le Prince; Dr. Weiss, 20, Avenue Jules Janin; 5. General and experimental pathology: Dr. Charrin, 11, Avenue de l'Opéra; Dr. Roger, 4, Rue Perrault; 6. Pathological anatomy: Dr. Letulle, 7, Rue de Magdebourg; 7. Internal pathology, corresponding to our Section of Medicine in part: Dr. Rendu, 23, Rue de l'Université; Dr. F. Widal, 155, Boulevard Haussmann; 8. The medical diseases of childhood: Dr. Marfan, 30, Rue la Boétie; 9. Therapeutics: Dr. Gilbert, 27, Rue de Rome; 10. Pharmacology: Dr. Chassevant, 70, Rue de Rennes; 11. Materia Medica: Dr. Chassevant, 70, Rue de Rennes; 12. Neurology: Dr. P. Marie, 3, Rue Cambacères; 13. Psychiatry: Dr. Ant. Ritti, The Charenton Asylum, Seine; 14. Dermatology and Syphilography: Dr. G. Thibierge, 7, Rue de Suresne; 15. General surgery: Dr. Walther, 21, Boulevard Haussmann; 16. Surgery of children: Dr. A. Broca, 5, Rue de l'Université; Dr. Villemin, 58, Rue Rue Notre Dame des Champs; 17. Urinary surgery: Dr. Desnos, 31, Rue de Rome; 18. Ophthalmology: Dr. Parent, 26, Avenue de l'Opéra; 19. Laryngology and Rhinology: Dr. Lermoyez, 20 bis, Rue la Boétie; 20. Otolaryngology: Dr. Castex, 30, Avenue de Messine; 21. Stomatology, including certain dental diseases: Dr. Ferrier, 39, Rue Boissy d'Anglas; 22. Obstetrics: Dr. A. Bar, 122 Rue La Boétie; Dr. Champetier de Ribes, 28, Rue de l'Université; 23. Gynecology: Dr. Hartmann, 4, Place Malesherbes; 24. Forensic medicine: Dr. Motet, 161, Rue de Charonne; Dr. Thoinot, 8, Rue de l'Odéon; 25. Military medicine and surgery: Dr. the Minister of War, Paris; 26. Naval medicine: Dr. Laugier, the Minister of the Marine, Paris; 27. Colonial medicine: Mons. Kermorgant, the Colonial Ministry, Paris. The names of those duly qualified medical men who desire to attend the Congress, with a visiting card and the subscription of £1, should be sent to either of the Honorary Secretaries of the International Committee for the United Kingdom—Dr. Garrod, 9, Chandos Street, London, W.; or to Mr. D'Arcy Power, 10A, Chandos Street, London, W.

The Medico-Psychological Association.

THE date of examination for the certificate of this Association will be December 14th. The examination will be held simultaneously in London, Edinburgh, Glasgow, Dublin, Aberdeen, and Cork. Candidates intending to present themselves must give fourteen days' notice to the Registrar, Dr. Benham, Fishponds Asylum, Bristol. Fuller particulars will be found in our advertising columns.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

REPRINTS.—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them, at half the usual cost, on application to the printers before the type is broken up.

A PHILANTHROPIC ADVERTISEMENT.

We have been asked to give publicity to the offer of a certain firm of dentists, who shall be nameless, to supply a hundred sets of teeth every year gratis to the poor. For reasons which our readers would appreciate if we disclosed the identity of these pseudo-philanthropists, we find ourselves unable to comply with the request, the more so seeing that none of our readers are likely to wish to avail themselves of this *largesse*.

H. S.—No one heeds the vapourings of the little journal referred to, and the publication of your letter would do it unappreciated honour.

ALIMENTARY VIVISECTION.

A CORRESPONDENT calls attention to the advertisement of Benoit's Real Turtle Soup which is "guaranteed to be made from the live turtle only," and he suggests that if this claim be authentic the Society for the Prevention of Cruelty to Animals, or the Anti-Vivisection Society, ought to take action. It may be surmised that the sentence in question is not really intended to bear the construction which our correspondent puts upon it, but the manufacturer will doubtless enlighten our readers on this point.

M. L. S.—The renovation of the drains is an expense the incidence whereof will depend upon the terms on which you hold the premises. If you have subscribed to a repairing lease, the cost, we imagine, would fall upon the tenant, *e.g.*, yourself.

ANTI-FLEA MEDICATION.

A correspondent writes:—The suggestion to take sulphur dragus as a protection against the bites of fleas, *et hoc genus omne*, though original, will, I fear, not commend itself for general adoption by those who suffer from the close attention of the lively flea. The cure would, I fancy, be found worse than the disease, as those using the sulphur would (to say the least) be in "bad odour" with their acquaintances, and at once convey the information to those who had heard of the sulphur, "preventive" that the users evidently suffered from "Phlebitis"!

ANTI-BOER.—The initial velocity of the bullets of the service rifles of various European armies differs. That of the Lee-Metford is 2,000 feet per second, that of the French Lebel 2,073, that of the German Mannlicher 2,034, of the Spanish Mauser 2,285, of the Italian Carcano 2,329. The Boers are said to be armed principally with the Mauser, which, so far as penetrating power is concerned, judging from the initial velocity of its projectile, is a very serviceable weapon.

A. T. Y.—We have considered the subject of our correspondent's complaint, and will send him a private note.

J. B. (Colnbrook).—You are certainly entitled to charge for the visit, even though you were unable, under the circumstances, to take part in the treatment. It would, however, be wise to bear this fact in mind in estimating the value of the time occupied in going to and fro.

Meetings of the Societies and Lectures.

WEDNESDAY, NOVEMBER 8TH.

HUNTERIAN SOCIETY.—8.30 p.m. Discussion on the Treatment of Typhoid Fever (opened by Dr. N. Pitt).

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.—4.30 p.m. Dr. T. D. Savill: Prurigo and Pruritus. (Post-graduate Course.)

THURSDAY, NOVEMBER 9TH.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 p.m. Card Specimens. 8.30 p.m. Papers:—Mr. A. Lawson: Corneal Horns.—Mr. E. T. Collins and Mr. C. D. Marshall: Two Cases of Primary Tumour of the Optic Nerve.—Mr. J. Griffith: Iritis a sequel of Gonorrhoea.

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. Purcell, Dr. H. Snow, and Mr. Bowreman Jessett. Papers: Dr. R. H. Hodgson: A Case of Tuberculous Peritonitis simulating Abdominal Tumour, Operation, Recovery.—Dr. J. Oliver: On the Physico-Chemical Conditions concerned in the production of Version of the Uterus.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—5 p.m. Dr. D. Grant: Differential Diagnosis of Nasal Obstructions.

FRIDAY, NOVEMBER 10TH.

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8.30 p.m. Papers:—Mr. H. B. Robinson: Acute Intestinal Obstruction due to an Intussusception of Meckel's Diverticulum.—Mr. J. Bland Sutton: On a Case in which Primary Nephrectomy was performed for complete Rupture of a Kidney.—Dr. N. Dalton: A Case of Enlarged Spleen due to Congenital Volvulus of the Stomach and Transverse Colon and simulating Splenic Anæmia.

Vacancies.

Bracebridge Asylum, Lincoln.—Junior Assistant Medical Officer—unmarried. Salary £125 per annum, with furnished apartments—board, attendance, &c.

Cumberland.—Qualified Indoor Assistant. Salary £100. Apply, "Cumberland," MEDICAL PRESS Office, Dublin. (See Advert.). Apply to the Clerk to the Asylums Committee, Office, 6, Waterloo Place, S.W.

Infirmary of the City of London Union.—Assistant Medical Superintendent at the Infirmary of the Union, Bow. Salary £156 per annum, with furnished apartments at the Infirmary, rations, and washing. Apply to the Clerk to the Guardians, 61, Bartholomew-close, E.C.

Preston Royal Infirmary.—Assistant House Surgeon. Salary £50 per annum, with board, lodging, and washing, &c.

Royal Infirmary, Hull.—House Surgeon for two years, unmarried. Salary, 100 guineas per annum, with board and furnished apartments.

Suffolk General Hospital.—House Surgeon. Salary, £100 a year, with board, lodging, and washing. Apply to the Secretary, Bury St. Edmunds.

Three Counties Asylum.—Assistant Medical Officer, unmarried. Salary commencing at £125 per annum, with board, apartments, washing, and attendance. Apply to the Clerk to the Visiting Committee, St. Neots, Hunts.

Appointments.

BARKER, W. H., L.R.C.P. Edin., M.B.C.S., Medical Superintendent for the Ararat Lunatic Asylum, Victoria, Australia.

BOON, J. G., L.R.C.P., L.R.C.S., Irel., Medical Officer for the Broseley Sanitary District of Shropshire.

BRADFORD, P. P., L.R.C.P., M.B.C.S., Medical Officer for the Bracknell Sanitary District of the Easthampstead Union.

BUNBURY, EDWARD GARRETT, L.R.C.P. Lond., M.B.C.S., Civil Surgeon, has been appointed to the temporary medical charge of the troops at Bristol in the medical staff of the district.

BUTTERWORTH, J. J., M.B., B.Ch., Junior House Surgeon to the Manchester Royal Eye Hospital.

CHURCH, B. E., L.S.A. Lond., Medical Officer for the Fourth Sanitary District of the Stroud Union.

CLEGG, J. GRAY, M.D., B.S., F.R.C.S., Honorary Assistant Surgeon to the Manchester Royal Eye Hospital.

DUNWOODY, W. G., M.D., B.Ch. Dub., Medical Officer of the Ely Workhouse.

HARRIS, S. C., L.F.P.S. Glasg., Medical Officer for St. Mary's Parish, Ely.

McLAREN, J. B., M.B., B.Ch. Irel., Medical Officer for the Workhouse of the Salford Union.

MIDDLEMIST, R. C., L.R.C.P. Lond., M.B.C.S., Medical Officer for the Ryhall Sanitary District of the Stamford Union.

SANFORD, J. C., Civil Surgeon, to the medical charge of the troops at Bodmin.

STANWELL, ST. JOHN, M.B., C.M. Ed., M.B.C.S., Medical Officer for the Barnack Sanitary District of the Stamford Union.

WHITELAW, F., L.R.C.P. Lond., M.B.C.S., Medical Officer for the Second Sanitary District of the Holworth Union.

Births.

BEST.—On October 31st, at 1, Cambridge Terrace, Dover, the wife of W. J. Duncan Best, M.B.C.S. Eng., L.S.A. Lond., of a daughter.

BLOMFIELD.—On November 1st, the wife of Geo. Wills Blomfield, M.B.C.S. Eng., L.R.C.P. Lond., and L.S.A. Lond., Horsefair, Portefract, of a son.

GALETTLY.—On November 2nd, at Sycamore House, Northwood, Norfolk, the wife of Wm. Glog Galletly, M.B., C.M., of a son.

HOLDEN.—On November 6th, at 108, Castle-hill, Reading, the wife of George Herbert Rose Holden, M.A., M.D., Cantab., of a son.

Marriages.

BLACK—ANDERSON.—On November 2nd, at Trinity Church, Hampstead, Captain W. C. Black, Indian Staff Corps, son of the late Robert J. Black, M.D., to Hope Gordon, youngest daughter of the late John Anderson, Esq.

HOME-ROSS—HARREL.—On November 2nd, at St. George's, Hanover Square, London, J. Home-Ross, F.R.C.P. Ed., only son of Major Hamilton Ross (late I.M.S.), Ballynacreeva House, Co. Antrim, to Maude, elder daughter of Sir David Harrel, K.C.B., Dublin.

Deaths.

MACKAY.—October 24th, at 85, Finborough Road, South Kensington, after a protracted illness, of typhoid fever, Stephen William Mackay, L.R.C.S.I., L.R.C.P., L.M., aged 49 years.

MCCARTHY.—October 24th, at Wingfield, St. Mary Church, Torquay, Michael Joseph McCarthy, late Fleet-Surgeon, R.N., aged 45.

Vienna Clinical Lecture.

ALIMENTARY GLYCOSURIA IN PREGNANCY.

By DR. HOFBAUER,

Of Prof. Schauta's Clinic of Gynaecology, Vienna.

THE glycosuria of pregnancy has recently become one of the most important subjects for investigation in gynaecology that modern science has to solve, and may probably result in the establishment of another diagnostic sign of that physiological condition that has puzzled clinicians in the past when a forensic test has to be applied. It is not long since Strumpell and Strauss startled us with the announcement that sugar in the urine of a pregnant woman was a normal physiological condition. Why it should appear in pregnancy in a healthy state and disappear after parturition was on the first glance easily explained by pressure, reflex, &c., &c.; but when it was discovered that other pathological pressures such as tumours, moles, &c., did not produce this saccharine condition, the wonder began to increase where the limit ceased.

In the normal healthy organism large quantities of saccharine matter can be absorbed, assimilated, and burned in the body without any appearance of glycosuria, but in the case of pregnancy commencing in the second month some defect occurs in the assimilation as the blood soon becomes hyper-glucæmic which is thereafter rapidly eliminated by the renal organs. Various theories have been propounded for this phenomenon, and among the firmest offered is an alteration of the nerve system giving rise to the term neurogenic glycosuria. Another views this with scepticism, and advocates a toxic condition as the proximate cause of the disorder of which we have testimony in alcoholic, lead, and opium poisoning, giving rise to the term toxicogenic glycosuria. Noorden has still another form, which he has demonstrated in acute fevers, and to which he has applied the term febrile glycosuria.

Among the first to put these theories in some measure to the test in pregnancy were Lanz and Jacksch, but feeling dissatisfied with some of the results commenced, under the guidance of my chief, Professor Schauta, to confirm or disprove some of the anomalies in the records that lead by inference to different conclusions. The first step was to discover the earliest period that sugar appeared, which was found to be the second month of pregnancy.

The next point was to discover how much sugar could be taken in without interfering with this assimilative disorder. The first step was to keep a register of the urine for several days before commencing the experiment. After this one hundred grammes of chemically pure grape sugar were given fasting every morning in coffee or brandy and water, and after an interval of one-and-a-half to two hours, the urine was drawn

off by means of a catheter and carefully analysed. This arrangement had no perceptible effect on that patient's appetite as she took her breakfast as heartily as if no experiment were carried on. Carbohydrates, it may be noted, were not allowed to be used during the periods of examination.

Forty-five cases in different stages of pregnancy were thus treated, at the same time keeping as near the examples of Lanz, so thus any discrepancy might be instantly observed in the corresponding epochs. Thirty-nine of the cases gave positive results, the other being before the end of the second month of pregnancy, when the saccharine condition of the urine commences and is found to gradually increase till the end of pregnancy, thus confirming the assumption that the assimilation limit is gradually reduced as the uterus increases.

With this recent knowledge before us it might be expected, from a forensic point of view, that the presence of sugar in the urine would be an infallible confirmation of the pregnant state. That, as far as we know at present, is a faithful diagnostic symptom in the normal physiological condition, but, unhappily for us, the pathological gravid state gives negative results, and for what reason cannot yet be clearly elucidated.

In ectopic pregnancy, for instance, I find that out of eight cases none of them had glycosuria, although all aborted, with hæmatocele forming in some. The formation, growth, and expulsion of moles had an equally negative result. There is another particular worthy of note where intra-uterine life goes all right till the death of the fetus, when sugar disappears in the urine as if no pregnancy had occurred.

These facts inevitably force us to the conclusion that glycosuria is a normal physiological condition where the growth and development of the ovum is undisturbed; that the presence of alimentary glycosuria is due to some alteration caused by the retention of the fructifying germ in the uterus. Lanz attempted to prove from his experiments that this alimentary glycosuria in pregnancy was analogous to Bunge's, who found that the glycosuria was due to an absence of iron in the food taken by the pregnant female. This idea has happily been abandoned for changes in the nerve system; alterations in the circulation of the blood which may affect the internal organs of the abdomen, and thus modify the metamorphosis during the gravid period.

From the inference obtained by animal experiments a this transitory form of glycosuria is due to injury of the glycogenic apparatus which first produces hyperglycæmia, and subsequently glycosuria. Nothing, however, can be traced to any lesion to account for the temporary presence of sugar; indeed, the opposite exists as we have seen in pathological conditions where no sugar is to be found.

This phenomenon has led investigators to explore the blood with no more satisfactory results. No pathological product of any note except the glucose can be discovered. Livierato who has spent a

considerable portion of his life at the subject, affirms that the glycogen is easily demonstrated, and that a form of leucocytosis coincides with the terminal part of pregnancy when the glycogen can be found both intra- and extra- cellular. On the first day after parturition the cells begin to lose this glycogen which rapidly disappears from the blood altogether in a few days after.

I have made repeated examination of the colostrum in the gravid state with Ehrlich iodine—mucilage—solution, which is composed of pure iodine 1.0 gramme, potassium iodide 3.0 grammes, and mucilage of gum acacia 100.0 grammes. Under the microscope the cellular element had the characteristic brown colouring; some had dark granular nuclei and flukes; others with diffuse colouring of the cell plasma. My results might be considered negative, as no differentiation from other diseases in gynaecology could be deduced. I have been unable to throw any light on the controversy which still rages concerning these micro-chemical reactions in the presence of iodine which Ehrlich affirms proves the presence of glycogen, while Kühz positively affirms the contrary. There is no doubt of the iodine reaction, but how it is to be interpreted we cannot determine with any amount of accuracy; possibly it is due to some deep structural changes in the blood and colostrum during pregnancy that we are not yet able, chemically, to follow with precision.

THE TREATMENT OF ACUTE PSYCHOSES BY REST IN BED.

By DR. P. SÉRIEUX,

Physician to the Asylum for the Insane for the Department of the Seine.

[SPECIALLY TRANSLATED FOR THE MEDICAL PRESS AND CIRCULAR.]

TREATISES and special reviews of therapeutics usually deal very briefly with the treatment of mental disease. This domain is for many *terra incognita*, and in the absence of facts mere surmises are accepted. It is generally believed that all psychoses are incurable, though in reality a cure is effected in 60 per cent. of the cases. The douche, the strait jacket, and the padded cell are still held by many to be the only things to which lunatics are amenable, though these methods of treatment have been rejected by modern psychologists. It is quite unnecessary to insist on the disastrous consequences of such prejudices. On the one hand, cases are not altogether rare in which the doctor, called to a patient with an attack of acute mental disorder—a disease eminently curable—can, and ought to resort forthwith to active measures; on the other hand the beginning of mental disorders is a critical phase, as regards the efficacy of medical intervention. The future of the patient often depends on the treatment adopted at the very outset of the mischief.

We propose to describe here a method employed with great success in acute cases of mental disease, viz., rest in bed. This treatment is quite easy of application either for private patients or in special institutions. Moreover, its immediate results in the cure of diseases of the brain as well as its indirect consequences in respect of the organisation of lunatic asylums, render treatment by rest in bed an innovation of the greatest importance. It is the commencement of a new era in the history of mental therapeutics. This very simple method will certainly transform the therapeutics of mental diseases and give us a fresh idea of how best to ameliorate the condition of the insane.

Before entering upon the subject of the physiological effect of this treatment, its results and its drawbacks, we must briefly discuss the means of carrying it out—the *technique*, in fact. One of the chief advantages is its simplicity; it does not require any special appliances and is applicable under all circumstances. Moreover, it does not oblige the patient to enter an asylum.

According to Schmidt, women are more refractory to the treatment than men. In certain cases (acute mania, restless melancholia, and pronounced hallucinatory confusion of ideas) the patients are with difficulty kept continuously in bed, but even when this is the case mechanical restraint by means of strait-jackets, &c., should be absolutely discarded. If the patient resents being kept in bed, we must imitate M. Magnan, who persuades them that they are ill, that they are feverish, and that rest in bed is necessary. For certain patients (paralytics, &c.), it is often sufficient to feed them, to supply them with newspapers, &c., for their objection to vanish. Often the mere presence of a nurse seated by the bedside and talking to the patient, holding his hand, apart from any more active measures, will obviate their desire to get up, even if markedly agitated. In cases of great and persistent excitement we may advantageously employ a bed on the floor, with the walls padded to a height of a yard or so; prolonged baths and hypnotics may also render service. Should these various measures prove inadequate, which is exceptional, and if the gentle suasion of one or two attendants has not the desired effect of inducing the patient to remain in bed, we must, nevertheless, avoid all struggling and all violence.

The patient is allowed to give the rein to his desire for movement, either in the ward, in the garden, or in an isolated room in which he should only be left for a short time, under close observation. When the crisis is over, an attempt should be made to exercise persuasion. The excitement is never permanent in the same patient, and it soon subsides. One important point to which attention must be called is that the treatment by rest in bed can be practised in our asylums without necessitating any costly appliances. There are, however, sundry dispositions which may prove advantageous, though by no means indispensable. The ward should be on the ground floor on a level with a conservatory, and looking on to a garden. Special attention should be paid to the ventilation and heating of this room. It is unnecessary to insist upon the obvious importance of perfect aëration and light in a place inhabited day and night by the patients. The most useful accessories are hinged panes, Hitsig's windows, the use of perforated panes of glass, blinds, &c., and the room should be rendered cheerful by flowers and other ornaments. The bathroom should be adjacent to the ward, and in some German institutions the bathroom and w.c. are combined. It has been found convenient to provide two wards, one being reserved for turbulent patients, having attached to it isolation rooms. The bed should, for hygienic reasons, be tolerably hard and rather low, in order to facilitate restraint should this be necessary, and also to minimise the ever-present risk of injury from a fall. The beds, or some of them, should be readily movable, so as to allow of their being wheeled into the verandah. There must be an adequate supply of blankets, and special attention must be paid to the temperature of the bed, especially in cases where there is redema or cyanosis of the extremities (melancholia). The temperature of the ward should be the same night and day, and high enough not to expose the patient to the risk of taking cold even if he throws off the bedclothes.

Needless to add that the sheets should be kept irreproachably clean, and that folds and crumbs are

to be avoided. The bed should be made twice a day. Among other devices employed in this treatment are screens, in order to give the impression of isolation, mattresses, of which the part corresponding to the patient's head can be raised to serve as a support for the back, and to enable the patient to sit up in bed without fatigue, a table by the side of the bed to facilitate the taking of meals, and lastly beds on the floor as already described.

At the commencement of the treatment, at any rate, the patient should be kept continuously in bed. He should lie flat in bed, as it is only in the horizontal position that complete rest is secured. Weir-Mitchell's method need not be too closely followed; indeed, we are of opinion that in the majority of cases it is preferable to relax the strict rules laid down by him for the treatment of neurasthenia. The patient may therefore be allowed to get up in order to discharge his natural functions, to take his baths, and even in some cases to breathe a more invigorating air in the garden. He should also be authorised to read and write, but meals must be taken in bed.

It is quite impossible to lay down any general rules, but the patient should leave his bed as seldom as possible at the beginning of the treatment. In asylums our practice is to allow most of the inmates to get up for half an hour during the morning, and this interval should be devoted to discharging the bodily functions (assisted, if need be, by an enema), washing, douches, and baths, which should be employed daily. During this interval, moreover, the ward should be thoroughly ventilated, the beds aired, the windows cleaned, and the beds carefully made.

Later on, as the patient improves, and the psychological symptoms subside, the treatment may be gradually modified by allowing the patient to lie on a sofa in the verandah, and to sit at table for his meals. Later on still he may get up for two or three hours in the afternoon, and finally, when he is well on the road to recovery, the patient may be allowed to get up daily after lunch.

The duration of the treatment naturally varies within wide limits. In certain acute cases, such as alcoholic, hysterical, and epileptic mania, the patient may become calm and sensible within a few days, sometimes even within a few hours. In neurasthenia, Weir-Mitchell enjoins complete rest in bed for a period of from six weeks to two months, and he asserts that to allow the patient to get up too soon is to risk his forfeiting any gain in weight that he has acquired, and to cause the reappearance of symptoms of exhaustion.

In the majority of cases of the acute psychoses, the treatment by rest in bed should be enjoined for at least six weeks. Guislain advises rest for the first two or three months of the disease. If the malady persists for several months, if the appetite is satisfactory, and the mental symptoms have become less acute, it is hardly necessary to say that the patient need not be kept in bed continuously. The bed-treatment should only be applied in all its rigour during periods of exacerbation, the patient passing only the forenoon in bed during the intervals. As a general rule, in the absence of special indications, it does not appear advisable for a patient to be kept constantly in bed for more than two months.

We may add that the treatment by rest in bed does not constitute the Alpha and the Omega of the therapeutics of the acute psychoses. Although this treatment, as we shall presently show, is one of the most valuable acquisitions of modern psychiatry, it must not be looked upon as a universal panacea. According to the indications, it will require to be associated with various other therapeutical measures, such as hyper-alimentation, hydrotherapy, massage, Swedish gymnastics, electro-therapy, the opium cure, hypnotics, strychnine, &c., &c.

If the physiological effects of exercise are well known, the same cannot be said of the physiological effects of absolute rest in bed. This aspect of the question does not as yet repose on precise data gleaned from the results of prolonged bed treatment, and so far our investigations have been conducted on a purely empirical basis.

Dr. Guy, an English physician, found that rest in bed had a marked effect on the pulse, and that the average pulse rate in men between 25 and 50 years of age was 70.05 pulsations in the sitting position, whilst in the horizontal position it was only 66.62. In women of the same age it varied from 81.98 to 80.24, while in children between 11 and 15 years old, the rate was from 91 to 90. Fossagrives always recorded five or six pulsations less in the horizontal than in the erect position. The moderating action of the dorsal decubitus with respect to the heart beat is, indeed, well recognised; Weir-Mitchell states that the diminution of arterial pulsation is equal to twenty per minute; Roehrich, however, only recorded a loss of from four to eight pulsations.

Rest in bed does not act only on the heart, but also on the peripheral circulation. The horizontal position suppresses the influence of gravity, and it therefore favours hyperæmia of the brain and a readier return of the venous blood from the lower limbs to the heart. This influence is far from being insignificant, especially in certain diseases, such as melancholia, in which the force of cardiac contraction is markedly decreased. From another point of view, the peripheral circulation is modified by the more or less complete suppression of muscular contraction. Lagrange describes the muscles as the organs of the circulation (the peripheral heart). This contraction accelerates the flow of blood in the veins, and if this contraction is wanting, there is a tendency to blood stasis in the limbs. With patients who remain standing and motionless for long periods of time, the fact that rest in bed exerts a satisfactory influence on oedema and cyanosis is easily explained.

All authorities recognise that the horizontal position produces a marked slowing of the respiratory movements. According to Viault and Jolyet, the 23 respirations, which is the average in a standing adult, falls to 19 in a sitting position, and to 13 in the horizontal position.

Looking at the question from the point of view of general therapeutics, Manquat concludes that rest in bed is a valuable means of treatment in acute disease, in that it leaves all the strength of the organism free to assist in recovery; it moderates the movement of the heart and respiration, and checks metabolism. Quite recently experiments have been carried out under M. Toulouse with the object of ascertaining the physiological effects of rest in bed. Mr. Lacombe noted the slowing of the pulse and of the respiratory movements, the fall of the central temperature, and an increase of arterial tension.

Drs. Toulouse and Marchand recently published the result of their observations on the variations in weight produced by this treatment. Rest in bed, according to these authors, at first reduces the weight, it accentuates the process of emaciation in persons with a tendency to cachexia, such as general paralytics, and in those whose tendency is to put on flesh, in convalescents, for example, it tends to check any further increase in weight.

These conclusions must be received with some hesitation, they can only be explained by the loss of appetite, which results from prolonged rest in bed and by the absence of all muscular exercise. Moreover, Weir-Mitchell observed an actual increase of weight among neurasthenic patients kept in bed, and Neisser records the same effect in epileptics. Roedrich has also observed a rapid rise in the weight curve in cases of acute mania, melancholia, primary mental con-

fusion, and acute hallucinations treated by rest in bed, the increasing varying from 300 to 400 grs. a day. We must also bear in mind that for several years past Professor Hayem and other therapeutists (Ewald, Von Ziemssen, Nothnagel, Quincke, and A. Robin) have adopted the treatment by rest in bed for chlorotic and anæmic patients. The application of the method has a marked effect in checking the destruction of red corpuscles which the least muscular exertion causes in chlorotic patients, and, in addition it indirectly assists digestion by obliging the patient to quit wearing stays.

In short, rest in bed modifies and regulates both the cardiac function and respiratory movement, increasing arterial tension and lowering the central temperature. It checks the destruction of red blood corpuscles, and lastly it slows the process of intracellular oxidation, and consequently retards disassimilation, thereby favouring a gain of weight. In certain cases this economy in the matter of combustibles may be compensated by loss of appetite, followed by loss of weight (Toulouse and Marchand).

(To be continued.)

NOTES ON THE BACTERIOLOGY OF THE RHEUMATIC AND ALLIED DISEASES.

By ARTHUR S. WOHLMANN, M.D., B.S. Lond.,
Bath.

DURING the last ten years the belief has been gradually gaining ground that the rheumatic diseases are of microbial origin. Clinical evidence and analogy point so strongly in this direction that, even without bacteriological confirmation, the presumption amounts almost to a certainty.

It must be admitted, however, that the bacteriological proofs of the belief have been somewhat unsatisfactory, there being considerable discrepancy in the results of different observers. This is attributable, in part at least, to the unfortunate nomenclature adopted in regard to the "rheumatic" diseases, and before discussing the microbes described I would clear the ground by the adoption of a definite and reasonable classification. I would divide these diseases provisionally into four main groups.

1. *Rheumatism*.—(a) Acute rheumatism, and when this passes into a chronic subacute form (b) chronic rheumatism, which I would distinguish absolutely from "rheumatic gout" or "rheumatoid arthritis."

2. *Gout*.—(a) Acute gout. (b) Chronic gout with the same remarks.

3. *Pernicious Arthritis* which I would substitute for rheumatoid arthritis, a term which has been so loosely applied as to have lost all significance. Abroad the term "multiple arthritis deformans" has been largely used. By pernicious arthritis I mean a disease with the most pronounced and definite characteristics: a subacute painful polyarthritis, affecting mostly women, symmetrical, causing spindle-shaped swellings of the joints, and no osteophytic thickening or lipping of bone. In addition there are various trophic and toxic symptoms, such as muscular atrophies, glossy skin, cold, dripping-wet palms, pigmentation, anæmia, &c., the whole forming a perfectly definite clinical picture. (The points in diagnosis were illustrated by casts painted from life.)

4. *Osteo-Arthritis*, a chronic condition characterised by osteophytic formation and eburnation of bone. It may occur as the result of wear and tear, or as the final stage of rheumatism, pernicious arthritis, or gout, modified as to details of shape by the preceding diseases, but as distinct from these as is the dense envelope of connective tissue round an embedded bullet from the initial lesion.

It is obvious that in this disease one would not look for a microbial origin, while in acute rheumatism and in pernicious arthritis such an origin might reasonably be inferred.

Bacteriology of Acute Rheumatism.—The work of the principal English and foreign investigators was passed in review from Mantle in 1887 to Singer in 1897. Guttman, Birch Hirschfeld, Bouchard and Charrin, Triboulet, Sahli, Sacaze, Grün, and Singer found various cocci, either staphylococci or streptococci, while Achalmé, Lucatello, Leyden, and Riva found special organisms. The results of Achalmé were confirmed by Thiroloix and by Treboulet and Ceyon. These latter observers, however, found that Achalmé's bacillus was frequently associated with a diplococcus, and was only present alone in severe cases.

Examining the heart-blood and the cerebro-spinal fluid in two cases of acute rheumatism immediately after death, Achalmé found in enormous numbers, and in pure culture, a large bacillus resembling that of anthrax. Examining the blood of six living cases he found the same bacillus in pure culture in four cases, and associated with micrococci in two. The bacillus stained easily with aniline dyes, or by Weigert's or Gram's method, but best with feebly alkaline methylene blue. It was absolutely anaerobic, and grew best in liquid media, horse bouillon with a little glycerine being best of all, at a temperature of 30 degs. to 38 degs. C.

Sporulation was best observed in the amniotic fluid of a rabbit killed by inoculation. On the third or fourth day a spore appeared at the end of the bacillus, which assumed a bell-clapper form. The results of animal inoculation were described, and some interesting observations made with regard to its reaction to salicylates and its precipitating effect on urates in urine. A number of microscopic specimens were exhibited showing the bacillus.

Achalmé concluded that the bacillus in pure culture at first caused acute rheumatism, but that it seemed to "open the door to the microbes of secondary infection, which may persist alone at the decline of the disease, and this would explain the numerous cases in which they have appeared to be the pathogenic agents of rheumatism."

Pernicious Arthritis.—Schüller's bacillus was described, and a short account followed of the diplobacillus, which the author, Dr. Bannatyne, and Dr. Blaxall found in the synovial fluid of patients suffering from this disease, and which they look upon as pathogenic.

A delicate diplococcoid organism staining with difficulty, and forming on the fourth day "gold-dust" floating colonies in flasks of clear peptone beef-broth at 98 degs. F.

Chaffard and Ramon have since described an organism in this disease apparently identical with the above.

SOME CLINICAL FEATURES

PERSONALLY OBSERVED DURING

AN EPIDEMIC OF DIPHTHERIA, WITH ESPECIAL REFERENCE TO THE EFFECTS OF THE ANTITOXIN TREATMENT.

By PEERS MACLULICH, B.A., M.D. (Dubl. Univ.),
Assistant Medical Officer to the Joint Counties Asylum,
Carmarthen, South Wales.

As early as April of 1893 Professor Behring published a record of recoveries amounting to 80 per cent. from diphtheria by injecting 5 cc. of his own anti-toxic serum, this amount then containing 1,500

standard units. Dr. Aronson in the same year also discovered the value of the antitoxin treatment in similar cases; but it was not until Roux read his paper on the subject at the Eighth International Congress of Hygiene at Buda-Pest, in 1894, that this new treatment for an old and terrible disease could be said, by its astounding efficacy, to be really grasped by medical men all over the civilised world. The first recorded case of its use in England was that of Dr. Eastes', in July of 1894, in which he used Aronson's serum; and the following spring saw it employed by many medical practitioners throughout the United Kingdom.

But then, as even now, it was often only used as a last resource in severe cases, instead of being administered at the very beginning of the disease in all cases. Perhaps one reason why antitoxin is not used, and why diphtheria usually tends to spread so rapidly in any one locality, is that its early diagnosis is not always properly made; I refer, of course, to mild cases of the disease. There seems to be an unaccountable confusion as to diphtheria in the minds of some. I have seen typical cases of a mild form termed "diphtheritic sore throats"; such cases are not considered to be true diphtheria, and therefore are not notified, and consequently are a fruitful source of the spread of this disease, especially among school children. The reason for this distinction seems to be due to the apparent mildness of the attack. Yet these cases are as certainly diphtheritic as are those accompanied by graver constitutional symptoms and severer local signs, and are equally sources of danger to the community at large.

Cultivations of the Klebe-Loeffler's bacillus could always be obtained from these cases, and many of them subsequently bore out the diagnosis of diphtheria by developing post-diphtheritic paralysis, or cardiac failure, &c.

Being fortunate enough to be in the midst of an epidemic, I was enabled thus to try the effect of the antitoxin treatment in forty-five out of fifty-six cases of pharyngeal and faucial diphtheria.

The majority of cases were seen on the first day of their illness, and the following generally was the history of its onset. Namely: that on the previous evening the patient went to bed in apparently his usual health, but on the following morning he felt very languid, weak, and feverish, vomited his breakfast, and complained of his throat being painful for the first time. The sudden feeling of weakness and languor appealed to the patient at this early stage more than any of the other symptoms did, and thus made him seek medical advice. In all the cases the extreme pallor of the patient was very noticeable, and, at the same time, his pulse was rapid (120-140 per minute) and soft, but with this the temperature in many of the cases was not over 99 degs. F. (In only one patient did it reach 104 degs. F.)

Another constant sign was the enlargement of the post-cervical glands on both sides of the neck, whereas the tonsils and submaxillary glands were often only very slightly enlarged, and then only on the side corresponding to that on which the patch of false membrane was situated. On examining the throat, frequently a single patch of membrane was all that could be seen, and this in the majority of cases was situated on the right side. The patch was leathery in consistence and very adherent, surrounded by a narrow inflammatory zone, and left a bleeding surface behind it when torn away. In some of the cases it could only be seen with great difficulty, as it was small and nearly hidden behind the tonsil, this latter being somewhat enlarged, and presenting at the same time a glazy red appearance.

Even in those cases in which the patch of false membrane was very small, and the temperature normal, or almost so, still the diagnosis of diphtheria

could with reasonable certainty be made. For the marked constitutional disturbance, the extreme anæmia, and the rapid and soft pulse, were out of all proportion to the local signs of the disease, present in the throat; contrasting thus with cases of follicular tonsillitis, &c. The post-cervical glands, too, were always enlarged from the onset of the disease, whereas the submaxillary glands if they increased in size, only did so to a slight extent, and at a later period.

The character of the patch also helped towards the same diagnosis, it was tough and leathery, not pul-taceous like that seen in follicular tonsillitis, scarlet fever, stomatitis, &c., and was very tenacious to the subjacent tissues; and, moreover, it bore no definite relationship to the mouths of the crypts of the tonsils (a point of great weight in the diagnosis). The tonsils also did not enlarge proportionally to the size and extent of the patch, or patches, present. A most peculiarly penetrating and typical odour was noticed in many of the cases; and this was the more intense in character the larger the amount of membrane present.

Immediately the diagnosis was made (and also in many of the doubtful cases), antitoxin was injected as the first step in the treatment. As regards the site of injection of the serum, the region of the back at the angle of the scapula was chosen, chiefly because the insertion of the needle here seemed to cause less pain than when the abdominal wall was selected as the site of injection. There was another reason also why the former position was chosen, namely, nervous patients (especially children) not being able to see what was being done to them, were less liable, therefore, to become restless, and so, perhaps, in some of the cases the needle was saved from being broken through their fewer efforts to struggle.

Most of the serum was supplied by Burroughs and Wellcome, and varied from 4 cc. to 5 cc in amount; but either quantity always contained 1,500 standard units. The dried serum, although it keeps better for a longer period than the liquid preparation, was soon abandoned because of its slowness to dissolve in distilled water; moreover the liquid form, if kept in a cool, dark place, appeared to lose none of its efficacy, even four months after it had been sent out by the manufacturers.

Of course in the administration of the antitoxin all the usual antiseptic precautions were most carefully adopted; the syringe also was taken to pieces beforehand and well boiled in distilled water.

The after treatment of the case was as follows:—A mixture was prescribed containing 5 minim doses of tinct. stroph. (B.P. 1885), combined with 3 minim liq. strych. hydrochlor. every four hours for a few days. After this the patient was put on some form of iron mixture in order to combat the existing anæmia and debility. At the same time a 1 per cent. solution of lysol was used as an antiseptic mouth wash and throat application, and also a $\frac{1}{2}$ per cent. solution as a nasal douche; for disinfection of the throat is important with the object of preventing the development of the streptococci and staphylococci, which are generally so abundant in cultures taken from the diphtheritic patch. No solid food was allowed for some days, and after a primary purge the bowels were kept open daily. But what was insisted on perhaps more than anything else, was the absolute quietness of the patient, and the necessity of the recumbent position for about ten days. For it was observed that those who were allowed to sit up within a few days after the injection of the antitoxin, were they who subsequently were the most prone to develop cardiac weakness, and were also longer in recovering from the debilitating effects of the disease. In order to diminish the possibility of the spread of the disease, the patient was, of course, isolated as far as

it was possible, and only one person allowed to attend on him. All utensils, &c., were immediately washed in a 1 per cent. solution of lysol after the patient had used them; handkerchiefs were prohibited, old pieces of linen being used instead for the nasal discharge, so that they could be burnt immediately after use. Also for a fortnight after convalescence, the patient remained as much to himself as it was possible, and at the same time rigidly adhered to the use of the antiseptic mouthwash and nasal douche.

With regard to the effects observed on the patient after the injection of antitoxin, perhaps the most noticeable one was his changed expression of countenance; for instead of looking exceedingly ill, and appearing dull and listless, within twenty-four hours (in the majority of the cases) he was much brighter and stronger; the distaste for food had passed off, and he expressed himself as feeling almost quite well again. In most cases the temperature had fallen to "normal" within twenty-four hours; in a few, especially those who were not injected until the second or third day, it did not reach this level for at least another twenty-four hours. In not a single case among those injected did the pyrexia continue for three days. But with this drop in the temperature the pulse did not synchronously reach the normal either in rate or volume; it certainly was not so frequent, but nevertheless for many days afterwards it maintained an increase in rate, and was still somewhat soft.

Both these pulse changes, and also the enlargement of the post-cervical glands, were somewhat persistent after the other signs of the disease had passed off.

As regards the membrane, it had completely disappeared, or was only loosely hanging by a small portion to the subjacent tissues, within forty-eight hours in all of the cases (except one, in which it persisted for three days). The tonsils at the same time rapidly diminished to their normal size, and the nasal discharge also quickly decreased in amount.

Only two cases needed a second injection—one patient, a boy, had a recrudescence of the patch (as proved bacteriologically) fourteen days after the first one had disappeared. The other, a male adult, developed an extensive patch in his right nostril four days after the pharyngeal membrane cleared off. Both these patients, however, rapidly improved after the second injection.

Comparing those injected with the non-injected: Although in the whole number there was not a single fatal case, still the subsequent progress of the patients in both classes presented many striking differences. For as already mentioned, among those injected the membrane had disappeared in all of them within three days from the employment of the antitoxin. But on the other hand, the patch did not disappear among those who were not injected, until, on an average, the seventh day after the onset of the disease (in one case not until the tenth day); and also among the latter class there was always present an irregular pyrexia. But perhaps the most noticeable feature among those who were not injected was their protracted convalescence; during this latter they all had attacks of cardiac dyspnoea, and complained of great weakness in the legs; and the anæmia and marked debility, which were present from the onset of the disease, persisted for many weeks, and even for some months in three of the cases. Although none of those who were not injected developed post-diphtheritic symptoms, while four of the others did, still, this cannot be urged against the employment of antitoxin; for these four cases had contracted a very severe attack of the disease, and it is highly probable that if they had not been injected there might have been some fatal cases among the number. At all events, it is certain that they

would not have made such rapid recoveries as they did. In only thirteen cases was albuminuria detected, and these, too, were among the number of injected patients; but this complication, like the previous one, occurred in the severer cases of the disease.

That early injection bears a close relationship to a proportionally diminished mortality, and incidence of paralysis, is shown clearly by the statistics contained in the "Report of the Committee on the Antitoxin of Diphtheria" (Longmans, Green, and Co.). This same "Report" also shows that the cases in which the performance of tracheotomy became necessary, were nearly 50 per cent. less among those which had been injected, than among those which had not been so treated.

With regard to the incidence of paralysis occurring in diphtheritic patients, statistics show what at first sight appears to be a curious fact, that is, that the percentage is greater among the injected than the non-injected; but to read this rightly, it must be remembered that it has been shown that the duration of life of the fatal cases treated by antitoxin is greater than in those not so treated, and also that the mortality percentage is lower among the injected than the non-injected; these two factors in themselves therefore allow of a longer period of time, and of a larger number of cases, in which the occurrence of post-diphtheritic paralysis may take place.

As regards complications attributable to the use of antitoxin, the most usual ones observed are some form of rash. This is generally erythematous, urticarial, morbilliform, or scarlatiniform; it usually commences about the seventh day, and as a rule lasts only two to five days. In 20 per cent. of these cases the rash appears for the first time at or near the site of injection; but it may be uniformly distributed over the body, or may affect only certain parts, e.g., the extensor surfaces of the limbs. It must also be borne in mind that some form of eruption is occasionally liable to precede the onset of diphtheria; and the varieties that usually do so, are the morbilliform and the scarlatiniform; but these and the former types appear to have no influence on the ultimate result of the case; and the former are probably due to the action of the blood serum itself.

Pain in and about the joints (very rarely effusion) sometimes is a complication due to the injection of antitoxin, and to this, finally, may be added cellulitis or abscesses, which have been known to occur at the site of injection. These latter probably arise from the contamination of the serum in the process of bottling it, or from a want of proper antiseptic precautions at the time of its injection.

Lastly, it has been stated, that nephritis has been caused by antitoxin, but the proof of such a statement is wanting, for when antitoxin has been injected into a healthy individual, it has been found to have no effect upon the kidneys.

In conclusion, I may add from my own experience that I believe that the early employment of antitoxin diminishes the tendency to a fatal termination, and at the same time lessens the necessity for performing tracheotomy, while it also shortens considerably the stage of convalescence, and robs the disease of a great portion of its former terrors.

WE regret to announce the death of Dr. Reginald Southey, F.R.C.P.Lond., lately one of her Majesty's Commissioners in Lunacy, and for fifteen years Physician to St. Bartholomew's Hospital, and Lecturer on Forensic Medicine, and Hygiene thereat. He was appointed Gulstonian Lecturer in 1867, and Lumleian Lecturer in 1881, and was the author of several contributions to the standard and periodical literature. He died at the comparatively early age of 64.

Clinical Records.

JESSOP HOSPITAL FOR WOMEN, SHEFFIELD.

Case of Unilocular Cyst of Left Ovary—Operation—Recovery.

Under the Care of JOHN W. MARTIN, M.D.,
Hon. Medical Officer to the Hospital.

J—P—, æt. 59, was sent in from Swinton by Dr Fullerton, on July 19th, 1899, for a large abdominal tumour. The catamenia had practically ceased for 13 years, though there was one recurrence about 5 years after the first stoppage.

Menstruation commenced when she was 14 years of age, and was always regular and normal. She first noticed an increase in size last Christmas but thought she was merely getting stout. Since Christmas she has felt very poorly in herself, with smarting pains in the body. Percussion showed that the tumour extended close up to the ensiform cartilage and well into either flank—it was very tense. The sound entered the uterus 3½ ins. and to the right. My colleagues agreed with the diagnosis of ovarian tumour, and the suitability of the case for a section.

A section was made on August 4th, the cyst (unilocular) was laid bare and tapped, a very large quantity of fluid being drawn off; a small pedicle was secured by transfixion and a double circle of ligature, and the peritoneum sewn over the stump. The peritoneal toilet was carefully attended to, and the abdominal wound closed by five silkworm gut sutures. The patient made a good recovery, and was discharged on October 14th, the delay being due to granulation of one portion of the wound which was slow in healing.

It ought to have been mentioned that there were no adhesions of any importance.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, NOVEMBER 10TH, 1899.

SIR R. DOUGLAS POWELL, Bt., President, in the Chair.

MR. H. BERTRAM ROBINSON read the notes of a case of ACUTE INTESTINAL OBSTRUCTION DUE TO AN INTUSSUSCEPTION OF MECKEL'S DIVERTICULUM,

which occurred in a healthy little boy, æt. 5, who had been quite well up to forty hours before, enjoying good health, and never making any complaint, except of an occasional pain in the belly. After breakfast, on January 21st, he complained of nausea and feeling unwell, his bowels were relieved naturally. During the day he complained of pain in the belly, but his temperature was normal, and there was nothing found on examination to point to any serious lesion. Through the night there were frequent attacks of bilious vomiting with cramping pains about the umbilicus, hiccup and thirst. Next morning he seemed a little better, but he vomited after swallowing anything; there was no distension, and no lump could be felt in the belly; nothing could be felt in the rectum. His temperature was 99 degs., and pulse 130. In the afternoon the pain, which hitherto had been intermittent, was more continuous, and the belly was a little fuller. An enema was given, but there was no result; it was noticed, however, that the returned fluid showed a little blood staining. Mr. R. saw him in the evening in consultation and found him with a distressed look and very restless, complaining of the pain across the belly at the level of the umbilicus. His temperature was 99 degs. and the pulse 160. He was vomiting a clear watery bile-stained fluid. No flatus had been passed during the day. His belly was distended, coils of small gut being noticed in the upper part. On palpation there was no rigidity and no special tenderness; an ill-defined lump could be felt just above the outer part of Poupart's ligament on the right side,

with comparative dulness over it, but nothing else was to be made out, and the rest of the belly was resonant. In the rectum there was no mucous discharge and no lump, but in the fecal smear on the finger was noticed a little blood-stain. Immediate operation was advised and proceeded with. Under the anæsthetic the resistance above Poupart's ligament disappeared, but per rectum a lump was felt in Douglas's pouch, which could be pushed up by the finger and then grasped with the other hand above the inner part of the ligament and to the right of the bladder. It seemed firm and tubular, and of about three inches long. Its low situation and free mobility were rather puzzling. A mid line incision was made, and on opening the cavity clear fluid escaped but no lymph coagula. Two fingers were passed down into Douglas's pouch, when they seized the lump and drew it out of the wound. It was seen that it was intussuscepted small intestine forming a tumour about four inches long. Without much difficulty the main part of the gut was reduced, when a hardness presented with a cup-shaped depression in its centre; a little further reduction showed that the normal axis of the intestine was restored, and that the lump came from its free margin, proving it to be an inverted diverticulum. The reduction of this from its thickened contracted neck proved impossible, and so there was no alternative but to excise it. The edges of the gap in the intestine were brought together by Lembert's sutures, but owing to the doubtful state of the bowel at one point, it was thought better not to entirely close it, but to fix it in the abdominal wound. An additional reason for doing this was that the boy's condition forbade any lengthy resection. After the operation he revived for about two hours, and then somewhat suddenly collapsed and died.

MR. CHARLES SYMONS had had no personal experience of intussusception following Meckel's diverticulum, but he had seen two cases of obstruction from that cause. The first was in a little boy who had repeated attacks of pain on the right side, like that of appendicitis. The lad was seen on the fourth day, and was extremely ill. He therefore operated and found a diverticulum of small intestine round which bowel was twisted and gangrenous. The second was that of a man, æt. 26, who came in on the fifth day of an attack of acute intestinal obstruction. On opening the abdomen he found a very wide diverticulum round which bowel was folded. In both cases the intervention was too late to save life. He urged that the sooner these cases were attacked the better for the patient. He had done eight, only two having been successful. It was, however, interesting to notice that one of the successful cases was that of a child of twelve months with an intussusception reaching from the cæcum almost to the rectum, and his incision extended from the ensiform cartilage nearly to the pubes. The other was that of a child only eight months old in which he made an opening over the cæcum. The first case was seen within twenty-four hours and the second within forty-eight hours, and both made excellent recoveries.

MR. ROBINSON, in reply to the President, said it was difficult to speak with certainty on the question whether or not there would be any contraction after the operation. That would depend probably upon the area of the base of the diverticulum. If large, there might be some contraction.

PRIMARY NEPHRECTOMY FOR COMPLETE RUPTURE OF A KIDNEY.

MR. BLAND SUTTON, related the details of a case in which a man, æt. 35, was run over by a cab. On admission the patient showed marked signs of internal bleeding, and a large ill-defined swelling formed in the right loin. The overlying skin was not scratched, contused, or torn. Three hours after admission the signs of bleeding became marked, and blood appeared in the urine, so that there could be no doubt that the kidney had been severely injured. Through an incision in the right linea semilunaris, it was ascertained that the remaining abdominal viscera were uninjured; on detaching the peritoneum overlying the swelling in the loin the kidney was found

completely torn across at the junction of the lower with the middle third; the laceration had involved the renal vein, and blood issued from it with some force. As it was hopeless to attempt to suture the two parts of the kidney together the fragments were removed with the surrounding clot. The peri-renal region was lightly stuffed with gauze and the wound secured with interrupted sutures of silk-worm gut. The patient convalesced quickly and left the hospital for the convalescent home in four weeks from the date of the operation. Mr. Bland Sutton pointed out that the clinical features were so marked and the line of treatment so obvious that he thought there could be no difference of opinion as to the mode of treatment adopted. He suggested that the term "primary nephrectomy" should be reserved for cases in which the kidney was removed within twenty-four hours of the accident, and that where it became necessary to remove a kidney some days or weeks after such an injury, it should be called secondary nephrectomy. He further observed that our home literature contained very few records of primary nephrectomy for rupture of the kidney, and that a study of the *Centralblatt für Chirurgie* indicated that far too many cases are recorded from post-mortem observations, the patients often dying without surgical intervention. This, he held, was very regrettable, especially as the signs of this grave accident are in a large proportion of cases very clear and obvious.

Mr. G. R. TURNER related a very similar case in a man, æt. 57, who also presented a swelling in the right loin, with rapidly increasing dulness. He diagnosed rupture of the right kidney, and opened the abdomen in the same way as the author. The whole of the ascending colon and cæcum were black with extravasated blood which had come from behind. He incised the peritoneum to the right of the ascending colon, and in the midst of much blood clot found the kidney torn completely across. It was too mangled to admit of suture, so he removed it. Patient made a good recovery in spite of an attack of acute bronchitis, the cough on one occasion bursting open the wound and allowing a foot of intestine to escape. He said he was led to operate in that case forthwith by having seen, a fortnight before, a man who had rupture not only of the kidney, but also of the liver. The patient was intensely collapsed, and he had to wait until the third day before opening the abdomen. He found a slight laceration of the under surface of the liver with blood in the general peritoneal cavity, but not of recent date. There was enormous retroperitoneal extravasation evidently due to rupture of the right kidney. The patient vomited persistently and died in a week. He suggested that the vomiting might have been due to involvement of some of the sympathetic ganglia in the clot. He remarked that the amount of urea secreted in the first case after the operation was above the normal.

Dr. GOODIE ADAMS referred to a case in which there was a considerable but not very extensive rupture of the kidney, which was not followed by any discoverable hæmorrhage, i.e., the urine was not tinged with blood. The patient was a man, æt. 45, seen after a "buffer" accident who had various severe injuries to which he succumbed, and post-mortem a rupture of the left kidney was found, measuring half-an-inch, with a small quantity of blood in the capsule, but none had passed into the bladder. In contrast to that case he had had in private practice two cases of injury to young male adults followed by considerable hæmorrhage, in which the bladder was filled with blood. They both eventually recovered. Putting these three cases together he was disposed to question the diagnostic value of bleeding from the kidney. In neither of these two cases of recovery was the accident a severe one, one being a fall in jumping, and the other the result of a slip.

Mr. KELLOCK asked why the author removed the kidney transperitoneally, seeing that it would have been so much more convenient to have approached the kidney from the loin.

Mr. HOWARD MARSH thought the author was right in opening the abdominal cavity, but asked why, when he found he had to deal with a ruptured kidney, he did not close the wound and get at it from behind, externally

to the peritoneum. If he had wished to suture the kidney it would have opened into the peritoneum. He urged the value of saline injections when there was much collapse. With reference to the absence of any external signs of injury, he instanced the case of a lad who had been run over and soon died in whom there was no outward evidence of injury, but in whom, post-mortem, the left lung was found torn from its bronchus.

Mr. BLAND SUTTON, in reply, admitted that in adopting the course he had done he was treading on debatable ground. He had been brought up as a "loin" surgeon but had gradually come round to Mr. Knowsley Thornton's way of treating these cases. He had dealt with 25 cases of operation on the kidney through an abdominal incision, treated transperitoneally, and with a little care the peritoneum could be brought together so as to shut off the general peritoneal cavity, leaving a more convenient means of draining than that through the loin. In this respect he dealt with each case upon its merits. He believed the good results of saline injections could be obtained by repeated injections into the rectum, but he preferred making these injections after the operation because, if used before, they were apt to give rise to much oozing. His experience with the injections had been principally in the treatment of ruptured gravid tubes. He discussed the treatment of these cases by suture of the ruptured kidney which Bradford had shown would readily unite if the rupture were through kidney substance.

Mr. TURNER, in reply to the President, said there was a post-mortem in the second case, but no injury to intestine was found. He concurred in the view that the incision through the semilunar line was a good one.

Dr. NORMAN DALTON on a case of

ENLARGED SPLEEN, WITH CONGENITAL VOLVULUS OF THE STOMACH AND TRANSVERSE COLON, SIMULATING SPLENIC ANÆMIA.

A woman, æt. 38. The spleen was painless, and had probably been enlarged since her first pregnancy. It now reached to the right iliac fossa. There was no history of malaria, syphilis, or alcohol, and the liver was not enlarged. All the symptoms of anæmia were present, and the blood showed 21 per cent. of red discs, 20 per cent. of hæmoglobin, no increase of leucocytes, and no abnormal corpuscles. No hæmorrhages had occurred. She had noticed the pallor and debility for one year, and while under observation, remittent fever was present. Death occurred suddenly. The stomach was found to be strangulated and extremely distended by gas; and a perforation due to sloughing existed at the cardia. The enlargement of the spleen was such as would have resulted from obstruction of the splenic vein. Two other abnormalities were found. 1. The transverse colon lay above the stomach (in the anatomical position) and, before it reached the left lumbar region, it was bent in such a way as to encircle the insertion of the œsophagus into the stomach. This abnormality was congenital, because the apron of omentum attached to the transverse colon had not united with that attached to the stomach, a state of affairs which exists in fetal life. 2. The pylorus lay almost behind the cardia, so that whenever the stomach became distended the fundus, by rotating to the right and forwards, would half intertwist the cardia and pylorus, so as to narrow both orifices. The grip of the colon round the cardia was apparently not tight enough of itself to cause obstruction; but, when the spleen became large, the drag of its weight on the gastro-splenic ligament pressed the cardia tightly against the encircling colon. This could be demonstrated on the post-mortem table by traction on the lower part of the gastro-splenic ligament. Finally, some extra distension of the stomach produced such a twist of the cardia and pylorus that fatal strangulation of the involved tubes occurred. The position of the parts at the cardiac end of the stomach was such that the splenic vein may have been compressed from the first, but, from the history, it probably became loosened from its attachments at the first pregnancy and then increased in size from traction and torsion of its vein. The anæmia and fever can be

explained by the condition of the stomach. As regards diagnosis, lymphadenoma, leucocythæmia, malaria, and other splenic affections were easily eliminated, and he came to the conclusion that the large spleen was due to obstruction of the splenic vein, although he was not able to discover any cause for such obstruction. It will be noticed, however, that the blood condition (oligocythæmia and chlorosis without leucocythæmia), the large spleen, and the fever established a close resemblance between this case and the disease called splenic anæmia or splenomegaly. There were some minor differences, such as the absence of hæmorrhages, and the apparent long duration of the case. He would add that he was not quite convinced that Banti is correct in considering that splenomegaly is a "pathological entity," because, while the total number of cases of this affection, which have been recorded is still small, in several of those which were most carefully observed during life, no post-mortem was obtained; and, further, in a few of those in which a post-mortem was made, it has been shown that the symptoms could be explained without calling a new disease into existence.

Dr. PERCY KIDD did not think the condition of the stomach quite explained the anæmia or the fever. He observed that in some cases of cirrhosis of the liver the liver was but slightly enlarged, while there was an immense spleen with intense anæmia, and he suggested that possibly some of these cases might have been taken for a new disease which he thought they should be cautious in accepting.

Dr. DALTON, in reply, admitted that it was difficult to explain the anæmia, the connection of which with stomach disease had not been thoroughly worked out. He referred to a case in the *British Medical Journal* a fortnight ago, of removal of the spleen for "splenic anæmia," in which it was mentioned, however, that post-mortem extensive lymphadenoma of the abdominal glands was met with, yet it was labelled "splenic anæmia," and would probably go down as such.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD THURSDAY, NOVEMBER 2ND, 1899.

The President, Mr. H. E. JULER, F.R.C.S., in the Chair.

TREATMENT WITH ANTISTREPTOCOCCIC SERUM.

Dr. WASHBOURN read a paper on this subject. He first considered the question as to whether the various processes associated with the presence of streptococci were manifestations of a single disease or were distinct pathological entities. These processes were (1) all cases of cutaneous erysipelas; (2) most cases of puerperal fever; (3) many cases of septic trouble, passing under the names of septicæmia, pyæmia, &c. He pointed out that the clinical symptoms were not trustworthy indications of the specificity of a disease. A simple poison, such as lead, might cause cerebral symptoms, paralysis, or colic, according to its localisation. The character of the lesion was also an untrustworthy criterion depending as it did upon the strength of the virus, and upon its localisation. The mode of conveyance of the virus might determine its localisation. He concluded that the conditions above mentioned were manifestations of a single disease. The absolute proof of the relation between erysipelas and other allied conditions must depend upon the identity or non-identity of the associated streptococci. He pointed out that the determination of the identity of various streptococci was a difficult matter. After reviewing the evidence, Dr. Washbourn believed that there were distinct varieties of streptococci only distinguishable by their behaviour towards serum, and that these varieties of streptococci might produce either the same or different lesions in the human subject. He described the methods of preparing, standardising, and administration of serum. He quoted cases of pyæmia, septicæmia, puerperal fever, erysipelas, and infective endocarditis to show the value of the treatment. He stated that in his opinion the serum was of extreme value in certain cases, but that it was valueless in other cases apparently identical. This he attributed to their causation by

different varieties of streptococci, and he urged the desirability of using a second sample of serum from a different source if the first failed.

Dr. DEAN had no doubt as to the probable value of antistreptococcic serum in rabbits, although its action had nothing like the constancy of the diphtheritic antitoxin, for in one animal many cc. might be required to produce the effect produced in another animal by one cc. The death of a rabbit inoculated with a dose of a virulent culture causing death in a control animal, might be much delayed or altogether prevented. He thought that some cases of failure might be due to the injections being stopped too soon, for he had found swarms of living streptococci in rabbits as late as the ninth or even the thirteenth day. The varying virulence of apparently similar streptococci was insisted upon, and the remarkable fact had been noticed that two streptococci of the same initial virulence might show great differences in the ease with which the virulence could be increased by passage through rabbits. An attempt was now being made at the Jenner Institute to prepare a polyvalent serum by using streptococci obtained from different sources. In using anti-streptococcic serum it was advisable, as far as practicable, to make the injections at the site of infection.

Dr. GOODALL had tried the serum in a certain number of cases of severe malignant scarlet fever, but without observing any benefit. He pointed out that such cases occasionally recovered with ordinary treatment, so that too much importance must not be attached to the occasional recovery of a case after the use of the serum. He mentioned one severe case of phlegmonous inflammation of the fauces, in which he had employed the serum with apparently great benefit. There was much oedematous swelling with high fever and delirium. The temperature fell to normal, in two or three days the swelling subsided, and the patient recovered. Such a condition following scarlet fever was rare, but it was very fatal. In this case the diphtheria antitoxin had been used without benefit. It was thought by some that streptococci played an important rôle in some severe cases of diphtheria, but Dr. Goodall did not think there was sufficient evidence of this to call for the use of the two serums together in such cases.

Dr. H. A. CALEY alluded to cases of infective endocarditis, in which antistreptococcus serum had been given with negative results, and to a case of endocarditis of a subacute type, in which it appeared to be of service. The variable clinical course of erysipelas made it difficult to gauge the effect of any particular therapeutic measures. Occasionally, however, the serum appeared to exercise a definite beneficial action, and he gave particulars of a severe case of facial erysipelas, in which the administration of each dose of the serum was followed by marked improvement, the patient subsequently making a good recovery. It was noteworthy that some of the recorded instances in which the serum appeared to have been of conspicuous value, were cases of recent septic infection associated with a definite local lesion, so that the administration of the serum was employed in conjunction with local measures at the site of the primary lesion.

Dr. BLACKER was interested to hear Dr. Washbourn's opinion opposed as it was to the conclusions arrived at by Dr. Spencer in his report presented to the British Medical Association this year, and to the report of the sub-committee of the American Gynecological Society. The question was an exceedingly difficult one to decide, since it was difficult to say at the onset of a case of septic infection, whether it was going to run a severe or a mild course, and the total mortality of cases of puerperal streptococcic infection was not more than 5.8 per cent., Dr. Blacker's own experience had been entirely disappointing. Most of the cases recorded were worthless from the absence of any bacteriological examination, and many cases of puerperal infection were due to a mixed infection which the serum could not be expected to influence.

Dr. EWART briefly referred to his experience with the serum. In a very severe case of infective fever in which the streptococcus was found in the blood marked improvement was observed after each injection, and the

patient recovered. In cases of endocarditis and of erysipelas the serum had not proved successful, and in a case of fetid bronchitis no improvement had taken place in the patient's condition, nor in the expectoration.

In his reply, Dr. WASHBOURN stated that he had noticed the same fact with regard to the pneumococcus, as Dr. Dean had observed in the streptococcus, viz., that two organisms might differ widely in the ease with which their virulence might be increased by passage through animals. The varying results obtained in the treatment of ulcerative endocarditis with antistreptococcic serum might partly be accounted for by the fact that not all cases were due to a streptococcic infection; some were caused by the pneumococcus, and others, again, by the staphylococcus. He had used a very powerful anti-pneumococcic serum which could now be obtained with success in a case of pneumonia following influenza. Dr. Washbourn did not agree with Dr. Blacker as to the mixed infection in cases of puerperal fever. The discharges might certainly contain many organisms, but the lesions were, he believed, due only to the streptococcus.

LIVERPOOL MEDICAL SOCIETY.

MEETING HELD THURSDAY, NOVEMBER 2ND, 1899.

Dr. ARMAND BERNARD, Vice-President, in the Chair.

Mr. NEWBOLT showed a woman, *æt.* 47, upon whom he had performed "cholecystotomy" five months ago. Seventy small calculi were removed, and the patient now had excellent health.

Mr. R. H. MURRAY showed a male child, *æt.* fourteen months, upon whom he had operated for

IMPERFORATE ANUS.

At the time of the operation the infant was one day old, and on making an incision in the normal position of the anus meconium was passed per urethram. The attempt to find the lower end of the bowel was then abandoned and left inguinal colotomy performed. The subsequent progress of the case was satisfactory; at the present time the infant was well grown and in good health. The question Mr. Murray raised was, can anything further be done for the child, or must he be compelled to go through life with an artificial anus. Considering the great disadvantages the boy would suffer, especially when he grew older, Mr. Murray suggested the advisability of opening the abdomen and endeavouring to bring down the present artificial anus or some other part of the large intestine to the normal position at the anus. This he believed to be quite possible, considering that in intussusception the ileo-cæcal valve occasionally projects beyond the anus.

Dr. HUBERT ARMSTRONG thought that an operation involving such grave dangers, and by no means absolutely necessary in order to prolong life, should not be performed until the patient was old enough to say for himself if he would take the risk.

Mr. PAUL thought that drainage of the intestine in iliac colotomy was best effected by the use of a glass tube. In regard to Mr. Murray's proposal to bring the bowel down to the region of the anus, he feared the attempt would fail, as the bowel below the artificial anus would be atrophied, while to bring the upper part of the sigmoid flexure down would involve so much division of its mesentery as to risk the vitality of the cut end. He would advise either that it be left alone, or that the proximal end of the bowel be separated and passed between the muscles for a couple of inches with the object of obtaining better control over the fæces.

Mr. THELWALL THOMAS regretted that the perineal operation was abandoned originally, further exploration with removal of the coccyx if necessary, would in all probability have led to the bowel. Now, however, it would be necessary to ascertain the condition of the bowel below the artificial anus, and any subsequent proceedings, if any, would be based on the knowledge thus acquired.

Mr. RICHARD WILLIAMS read notes of a "case of a foreign body, a small piece of steel, in the right eye" of a boy, *æt.* 15. The foreign body had entered the cornea at the upper and outer part and penetrated the iris at the periphery without injury to the lens. At first it was plainly visible behind the lens, but on an attempt at removal under an anæsthetic it disappeared during a violent attack of vomiting, and had not since been seen. First attempts with the Röntgen rays failed to discover the body. Ultimately, however, a good skiagraph by Dr. Holland showed its presence. The eye recovered perfectly, and had normal vision, but later on some turbidity of the vitreous came on with slight deterioration in vision, and it was a question whether the rays had had anything to do with this result. At present the eye is quiescent with vision = 3.

Drs. SHEARS, GROSSMAN and BICKERTON took part in the discussion which followed.

Drs. GROSSMAN and LOEWENTHAL read a paper on

AN ENDEMIC OF FOLLICULAR CONJUNCTIVITIS IN A LIVERPOOL SCHOOL.

A case of advanced follicular conjunctivitis without marked subjective symptoms was accidentally discovered and led to an examination of all the children of the same school. It was found that of 700 children 422 had follicular conjunctivitis (= 60 per cent.). The authors touched upon the appearances and symptoms of the disease with percentage of occurrence of the different stages; the prognosis of treatment and differential diagnosis. Patients and microscopic specimens were shown.

BRITISH ORTHOPÆDIC SOCIETY.

MEETING HELD AT THE ROYAL ORTHOPÆDIC HOSPITAL, OCTOBER 28TH, 1899.

Mr. REEVES in the Chair.

THE CHAIRMAN showed an improved instrument for the ambulatory treatment of congenital misplacement of the hip. This instrument kept up extension while the patient walked about. It allowed flexion at the knee and abduction at the hip. He drew the attention of the Society to the fact that he first employed this method of treatment a year and a half before Lorenz published a similar method. The difference lay in the use of plaster of Paris instead of a steel support. He was strongly opposed to the open operation for this deformity.

Mr. JACKSON CLARKE, Mr. MUIRHEAD LITTLE, Mr. ROBERT JONES (Liverpool), and Mr. HY. BAKER exhibited cases; and Mr. E. LUKE FRER and Mr. NOBLE SMITH showed skiagrams.

Mr. A. H. TUBBY read a paper on the

SURGICAL TREATMENT OF INFANTILE SPASTIC PARALYSIS.

After briefly summarising what is known of the pathology of the various forms of the affection, he said that in micro-cephalic idiotic children surgical operations were contraindicated. Craniectomy was disastrous. The occurrence of convulsions which indicated that sclerosing processes were still going on was another reason for not operating. Physicians and neurologists generally treated a contracted arm by advising that the sound one should be bound up so that the child would have to use the palsied one, and that the child should be taught to use its lower limbs and walk. This treatment was only effectual in slight cases. When there had been no convulsions for two or three years, when the mental condition was good and there was no athetosis the case was favourable for operation. In his opinion no retentive apparatus was of any use as it could not fight against the spastic muscles. It could only cause sores and increase of spasm. He would, however, make an exception in cases of talipes equinus where the foot could be flexed to a right angle with the leg. In such cases he anæsthetised the patient and forcibly dorsi-flexed the foot and fixed it in gypsum. If the

tendon were divided talipes calcaneus might result. If there was distinct equinus to ten or fifteen degrees beyond a right angle, tenotomy should be performed. The neurologists, however, were opposed to tenotomy. Gowers had said it was without the least benefit and was not justified. Tenotomy reacted beneficially on the mental condition, probably by diminishing the afferent impulses which were constantly arising from the spastic muscle. In more severe conditions when the adductors of the thighs and the hamstrings were contracted he preferred to divide the treatment into three stages, dealing first with the adductors, next the hamstrings, and lastly the tendo-achillis. By dividing these tendons in that order children could be made to walk easily and well. In the arm division of the pronator teres and its conversion into a supinator as described at the Society's last meeting gave good results, combined with open section of the flexor tendons at the wrist without any attempt at lengthening and suture. He suggested that at the knee the gracilis, &c., might be detached from the tibia, and used to strengthen the quadriceps by suturing them to its tendon.

Mr. JACKSON CLARKE referred to the occurrence of spastic paralysis in children after influenza, &c. He advocated tenotomy of all the affected tendons at one sitting, but section of the adductors was often followed by pain in the scar, and he, therefore, preferred to stretch, instead of dividing, them.

Mr. ROBERT JONES said that the great force of the spasm which in the adductors sometimes persisted under chloroform was most striking. Elongation of muscles by tenotomy allowed development of their opponents. He thought that most cases could be benefited by operation. A principle that should guide them was that a wide pedestal for walking was most necessary. It was no use to operate on the lower limbs unless the arms were or could be made useful, as much depended upon them in walking. After operation slow imitative movements were to be practised. These were more important than massage. He did not think that complete division of the adductors was practicable subcutaneously. He divided them by the open method, exercised part of the tendons and muscles, and kept the thighs abducted nearly to right angles for at least two months. He used a walking apparatus which held the limbs abducted.

Mr. NOBLE SMITH remarked on the striking divergence of opinions between orthopedic surgeons throughout Europe and America and physicians. He emphasised the importance of treatment after operation.

Mr. LUKE FREER agreed with Mr. Tubby and others as to the good effects of operations physically and mentally. He thought all massage and retentive apparatus useless without tenotomy.

Mr. MUIRHEAD LITTLE referred to the fact that in many of these cases labour was difficult or prolonged or premature. He thought that the intelligence was always sub-normal. He did not think convulsions always indicated progressive disease. He had operated in children subject to "fits" with good results. He entirely disagreed with the views of several previous speakers as to retentive apparatus. He had often found splints effective without tenotomy, and had seen the spasm, instead of increasing, diminish or disappear while they were used.

Mr. KEETLEY thought some cases were of infectious origin, possibly the infection was the same as that of infantile atrophic paralysis. Some he believed were of spinal and not cerebral origin. He thought arthrodesis of one leg might prove useful. He believed exercises alone did sometimes do good, tenotomy was generally needed.

Mr. CHISHOLM WILLIAMS said that he had operated on three idiotic cases. The parents preferred their children straight idiots rather than crooked idiots.

Mr. TUBBY briefly replied.

Dr. D. J. C. WATKINS has been elected to the post of Medical Officer of the Lincoln General Dispensary in place of the late Dr. E. C. Palmer.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, November 11th, 1899.

At a meeting of the Society for Innere Medizin, Dr. S. Munter delivered an address on

HYDROTHERAPEUTICS IN THE TREATMENT OF CARDIAC DISEASES.

He said that for some time there had been a dread of cardiac irritation caused by hydrotherapeutical treatment of diseases of the heart. This had been caused by Preisnitz, who had applied thermic irritation to its fullest extent, and had thereby done harm in such cases. Only in later times had physicians begun to treat these diseases systematically by saline and carbonic acid baths in which, however, heat played the principal rôle. Only slow progress had, however, been made, as the knowledge of nutrition and the function of the heart still presented too many lacunæ whilst pathological anatomy did not afford sufficient basis for treatment. Now as functional diagnosis was more complete, hydrotherapeutics in relation to cardiac diseases come to the front.

In passing on to the aim of therapeutics in the treatment of these affections, he drew attention to the exceptional position of the heart among muscles from its enormous activity with only short pauses. It must be assumed that in order to do such work it must possess peculiar adaptability for using nutrient material and for giving off waste products. It is in favour of this that the heart still makes its contraction when all other muscles of the body have ceased to act. The heart also possesses special reserve power to fit it for emergencies of increased activity. The chief remedy in cardiac therapeutics is digitalis, which calms exaggerated activity, and by raising the blood pressure brings about a condition of increased nutrition of the heart. The great usefulness of slowing of the pulse has been shown by experiment, according to which, the slower the heart beats the longer are the pauses between diastole and systole. So that, independent of the fewer contractions, the sources for recuperation are distinctly increased. Thermic stimulation in the form of cold acts exactly like digitalis, and finds its place especially where digitalis has already brought about the needful rest.

The speaker then turned to the special indications. He first discussed absolute and relative cardiac insufficiency; whilst in the case of the first treatment was of no avail, in the latter it was useful in a high degree. The stimulants were now made use of with special effect. Hydrotherapeutics are stimulating but not to such an extent as the centrally acting internal medicaments. When compensation is brought about by the latter hydrotherapeutics serve to carry it further and to maintain it. In acute endocarditis the local application of cold is useful from the first. The ice-bag ordinarily used acts too powerfully and presses too strongly. Leube's cooling tube apparatus acts better, but the extinction of heat is not equable as the lower strata of water become warm. The speaker had invented a cooling flask, with a permanent flow of cool water through it. After the application of cold pain ceases, the urine increases, and the cardiac activity diminishes. Digitalis always assists in cases of delay of compensation. Also

after compensation is set up cold serves as a tonic to the cardiac muscle. They used saline or carbonic acid baths, cold friction, packs, affusion, douches, according to what was required, the particulars of which were specified by the speaker. Care must be taken to individualise in each case, as hydrotherapeutics was an energetic means that could increase blood pressure by contraction of vessels. On the other hand, a depletory effect could be produced by action on the peripheral vessels.

At the meeting of the Society for October 30th, Hr. Karewski related two

CASES OF SUPPURATION IN THE LUNGS AFTER INFLUENZA

with demonstrations. The cases were reported as a supplement to an address by Herren Körte and Fraenkel on gangrene of the lungs after influenza, and were treated by operation on account of large cavities that had formed subsequent to attacks of that disease.

Case I. was that of a man who had extensive exudation with pleurisy after influenza in 1897. Puncture was not followed by recovery, but the symptoms continued, and a second puncture was made with evacuation of a large quantity of pus. A subphrenic abscess was diagnosed, and on April 6th, after resection of the eighth rib and incising a serous exudation escaped. On deeper incision a large abscess cavity was reached, which extended from the lungs to below the diaphragm and the perirenal tissues. Extensive resection of five ribs was then performed, incision through the diaphragm. The abscess cavities were made into one, but recovery took up several months, and a large lung fistula did not close up for 18 months. The speaker believed the case was one of primary abscess of the lung which had set up secondary suppuration in the pleura, subphrenic, and perirenal region.

Case II. was a woman of healthy family who was taken ill of pleurisy in January, 1899, shortly before her confinement. An empyema formed, which was treated by resection front and back, but which did not lead to recovery. In July the patient was admitted into the Jewish Hospital, in the surgical department of which the speaker was then doing duty for James Israel. The patient had two fistulae of the thorax, one behind and one in front, from which thick muco-purulent material flowed. The two fistulae did not appear to communicate with each other. Above them amphoric breathing was heard, and from this and from the prolonged duration of the illness, the speaker came to the conclusion that there was a cavity in the lung. Operation, July 14th.—An incision was made downwards that united the two fistulous openings, then the ninth rib was resected in order to get at the posterior fistula. It was ascertained by this that the two fistulae did not communicate with each other. After further resection of the sixth, seventh and eighth ribs, an empyema was reached between the diaphragm and the lungs, through which ran an artery. This was doubly ligatured and divided. The cavity was cleared out, and complete recovery had taken place. A Röntgen ray illustration showed clearly the defect in the thorax.

In conclusion, Dr. Karewski showed a patient on whom, two years ago, he had performed extensive resection for actinomycosis of the right lung. Numerous inquiries had been made of him as to the patient's

subsequent history. As the man's appearance showed, he was now perfectly well.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, November 11th, 1899.

BOSNIAN OPERATION FOR CALCULI.

At the Gesellschaft der Aerzte, Preindelsberger gave the meeting a racy description of how the Bosnian surgeon operates for stone in the bladder. The diagnosis is made by the bimanual method. Having decided to operate, two fingers are entered into the rectum above the stone, which is caught and pressed tightly down on the perineum; an incision is then made parallel and near to the urethra, until the stone is reached, which is next caught by forceps and extracted. The hæmorrhage is checked by pouring hot oil over the bleeding surface, or the application of boiled egg albumen. The results are not at all satisfactory. In a series of 160 cases he performed himself by this method while in the country, 20 per cent. died, and he had no doubt in his own mind that other practitioners had even much higher mortality.

He related two cases that had an urinary fistula in the perineum after the operation.

His exhibition of the knives, forceps and spoon used in the operation caused much amusement.

MALIGNANT MEDIASTINAL GROWTH.

Schiff exhibited a man, æt. 55, who has suffered for the last ten years from a great difficulty in breathing. The laryngoscope revealed a firm compression on the left side of the trachea. Over the upper part of the mediastinum, and in the left thorax there was great bulging, absolute dulness with venectasia of the overlying skin. Aneurysm and malignant growth was eliminated from the diagnosis by exclusion. By making a deep cough the patient could make the tumour rise prominently above the jugulum sterni, as a hard, knotty mass. The Röntgen rays were of little service beyond observing the movement of the enlargement behind the sternum. It is just possible it might be a movable goitre. Operating was the most rational course.

Weinlechner remembered several cases of movable goitre where the swelling produced a rushing sound as if from a ventilator at each respiration. Such a movable goitre may easily become incarcerated behind the sternum, as in the present case. He thought the operation practical, and the prognosis favourable.

Albert thought the tumour might turn out to be a dermoid cyst, but Schrötter thought this very improbable, as dermoid cyst of the mediastinum was a very rare occurrence. Again, the hardness of the tumour was against the hypothesis of a cyst.

BEZOARIC CALCULUS.

Schopf showed a bezoar stone of crinular origin taken from a young girl, twelve years old. On entering the stomach and draining off the fluid a longitudinal concretion was found with a tail extending down the duodenum 30 centimetres (11·8 ins.) in length. The hair of the stone had a bright red colour with projecting black hair; the former from the female head, and the black resembling horse hair. When dried the stone weighed 160 grammes or nearly six ounces.

The symptoms before the operation were vomiting, emaciation, and general malaise.

The diagnosis was a movable tumour easily felt through the walls of the abdomen, but whether it was a new growth or floating spleen could not be determined.

Bezoar are very rare in man, although they are frequently found in horse, cattle, sheep, chamois, and camel. In man they are usually met with in hysterical or mental imbeciles. They can be borne for a very long period without danger to life, ranging from six to twenty years. Inanition is the usual mode of exit.

The diagnosis of such cases is usually obscure, although the history in some cases will easily decide the correct state, such as the habit of chewing or biting the hair of the head or beard. As a rule, however, they are usually confounded with floating kidney or spleen, cancer of the stomach, or a fecal impaction in the transverse colon.

The therapy points to early gastrotomy. An interesting point in these bezoars is the growth of fungi peculiar to themselves (Schwarzwurzel).

XERODERMA PIGMENTOSA.

Kaposi showed two sisters from Italy who had been admitted to hospital for xeroderma pigmentosa, a disease first correctly diagnosed in 1870 as malignant, hereditary, and rapidly ending in death. The elder of the two cases showed the disease in a marked degree, the pigmentary production in some parts being quite lost, with atrophy and malignant tumours appearing all over the face, ranging in size from a small pea to a good-sized nut. The pigmentation was so deep over the parts affected that she resembled a nigger. One of the tumours had already destroyed the left eye; two of these growths were situated on the tongue. In both cases he proposed to scoop out the growths, although such a senile involutionary process gave very little hope of final success in the treatment.

He referred to the article he had already published of a family of seven who were all affected, and each died from the disease in rapid succession.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, November 12th, 1899.

EXOSTOSIS OF BOTH ORBITS.

Dr. CHEVALLEREAU recently brought before the Paris Society of Ophthalmology a woman, *æt.* 30, who had come to him complaining of disturbances of vision and exophthalmos associated with attacks of violent headache. The patient was kept under observation for nearly two years, during which time the condition had not undergone any marked change. The right eye projected 6 or 7 millimetres, and there was complete ophthalmoplegia. On palpation over the upper and internal angle of the orbit one could make out a hard, rounded mass, painless and almost fixed. At the external angle a similar but smaller mass could be felt, while the whole of the lower margin of the orbit was felt to be thickened by bony deposit. Later on, the sight of the left eye began to fail, and ultimately similar hard tumours were felt to be growing. In both eyes there was optic neuritis, most pronounced in the right eye. No local pain was at any time complained of, and the nasal mucous membrane was healthy. The patient's

general health had always been good, and the most careful questioning failed to reveal the presence of any morbid antecedent. Experimental treatment by mercury gave no result. Inasmuch as surgical treatment would entail total loss of vision, Dr. Chevallereau refused at present to advise it, although if the growths should further increase in size, this may ultimately become necessary.

VIPER POISON, PEPTONE, AND EXTRACT OF LEECHES AS COAGULANTS.

Mr. Phisalix has been making some further researches on the action of viper poison, peptone, and extract of leeches on the coagulation of the blood. He found that viper poison, which destroys the coagulability of the blood in dogs, does not afford any immunity against the coagulating action of peptone, and, conversely, injections of peptone do not inhibit the coagulating powers of the venom. This remark also applies to extract of leeches. He infers from these facts that the subjects in question do not influence the coagulation of the blood in the same mechanism.

Continental Notes.

[FROM OUR OWN CORRESPONDENT.]

INNSBRUCK.

As a desirable residence for winter the merits of this metropolis of the Austrian Tyrol are very insufficiently known to our British people. Innsbruck has many advantages which should attract hither a large "winter colony" of English and Americans.

It is a city of over 30,000 population, with all the incidents of an agreeable city life. An excellent university, with an efficient staff of professors, second to none in Austria outside Vienna. Its municipal schools are equally excellent, and there is an abundance of private and most competent tutors for those who prefer such education for their children. Life is economical; the hotels and pensions are good and very moderate in terms, and there are so many of them that all varieties of preferences can be readily suited. Villas and apartments, too, are abundant. There is an English church service, other Protestant churches, and many Catholic edifices with military and other attractive musical services. Good military and municipal bands play in the public gardens and skating rink; the Tyrolese are emphatically a musical people. The officers of the large garrison give balls during the season. In fact, the military and music add much life and colour to the social entertainments of Innsbruck. The theatre, museum, libraries, &c., are also good, and the shops likewise.

In these important items of a pleasant winter sojourn, Innsbruck offers many advantages and desiderata, of which the majority of elevated winter resorts are deprived. You find at Innsbruck all the winter amusements; skating, sleighing, tobogganing, ski-running, curling, the chase, and mountaineering; and added to these special winter pastimes at Innsbruck are the general advantages of a city life. For families, with children to educate, or with their education to complete, Innsbruck is unique in its advantages.

The climate is equable and beneficial to the convalescent, nervous, anemic, delicate, and especially the over-worked young or old; and our *fin de siècle* studies

in over-working of the young and not over robust renders a change of this nature of imperative importance. Winds are rare, and the clear, cloudless days, even in winter, are numerous. The rainfall is moderate, and the air dry and crisp.

A range of high mountains not only protect the city from north and east winds, but they attract and gather the rays of the southern sunbeam, and throw their heat back upon the valley, so giving to it a temperature rarely found at so high an altitude. As one writer well says, "the strength of the north and the tenderness of the south here unite in pleasing harmony." The beautiful blue transparence of the sky throughout winter is an object of universal comment.

Situated at the junction of the Arlberg and Brenner railroads, Innsbruck is readily accessible from Switzerland, Germany, Austria, and Italy. It is really too convenient a "thoroughfare," for many thousands pass rapidly through it without stopping long enough to even see, much less appreciate, the beauties and advantages of this

"Olden town, so true;

Amongst its green leaves lying

Like drops of pearly dew."

Its chief hotels are so near the railway station that one has simply to step across the square to enter their portals. Commencing this week, new and quicker trains have been added, facilitating the connections between Innsbruck and Milan, Venice, and the Italian Lakes. Passengers can now leave Milan daily at 7.30 a.m., and arrive at Innsbruck 8.45 p.m. This train has three classes; carriages changed at Fink and Ala. Passengers from Venice leave there 8.45 a.m., and join the Milan train for Innsbruck at Verona. A first-class express train also starts from Milan every morning at 9.35 and reaches Innsbruck at 7 p.m. the same day, without any change of carriages. Trains are now equally convenient from Innsbruck to Milan and Venice. These improved train-services are due mainly to the efforts and influence of Mr. Landsee, the proprietor of the Hotel Tyrol, at Innsbruck; who for many years has been steadily persistent in all matters adding to the prosperity of the place; and especially those which added to the well-being, comforts, and pleasures of the visitors to Innsbruck and the Tyrol.

The Operating Theatres.

CANCER HOSPITAL, BROMPTON.

REMOVAL OF BROAD LIGAMENT CYST.—EXTENSIVE ADHESIONS.—Mr. CHARLES RYALL operated on a woman, æt. 26, who had been admitted for an abdominal tumour. The symptoms had extended over a year after her accouchement which was severe, and kept her confined to bed four weeks, during which time she suffered a great deal of pain. On getting up she noticed a swelling in the abdomen, which had been gradually enlarging up to the date of her admission. She had suffered a great deal from abdominal pain which was frequently of a paroxysmal character. She was also much troubled with constipation. The catamenia were regular, there was no excessive loss, but a good deal of dysmenorrhœa. On examination a smooth round tumour could be felt in the right iliac fossa, extending into the hypogastrium, and upwards as

far as the anterior superior iliac spine. There was a fair amount of mobility and no pain on manipulation. *Per vaginam*, the uterus was found to be retroverted, fixed and pushed over to the left side, and the tumour could be bimanually manipulated through the right lateral fornix. On opening the abdomen through a median incision extensive adhesions of the omentum, small intestine, and sigmoid to the tumour and uterus had to be dealt with before any view could be obtained of the pelvic organs, and it was then found that the tumour was a broad ligament cyst; this was enucleated by dissection, with a considerable amount of difficulty owing to the inflammatory changes surrounding it. The peritoneum investing the cyst was then closed by suture. The uterus was next liberated from the pouch of Douglas where it was found to be intimately adherent. There was a great deal of persistent hæmorrhage from the breaking down of these latter adhesions so much so that it was deemed advisable to drain the abdomen by gauze passed through the posterior fornix into the vagina. The patient bore the operation well, and before closing the abdomen which was done in three layers, a pint of normal saline solution was poured in, and left in the abdominal cavity. Orders were given that on the patient's removal to the ward, the foot of the bed should be well raised. Mr. Ryall said that there was no doubt that the extensive adhesions were the result of an attack of pelvic peritonitis which followed the patient's confinement, and none of them presented difficulties of an exceptional character, though a considerable amount of time and patience had to be expended in freeing them. Owing to the oozing, especially in the pouch of Douglas, it was considered necessary, he pointed out, to drain, and the vaginal route was therefore resorted to, as he considered it the best. Drainage through the ordinary laparotomy incision has, he said, two grave disadvantages. First, it weakens the abdominal wound at the site of drainage, causing liability to a subsequent hernia. Secondly, any ligatures in the abdomen may become infected, and thus lead to a persistent sinus. In breaking down the adhesions a great deal of raw and lacerated surface was left, and as those damaged tissues were prone to infection, and the growth of micro-organisms introduced at the time of operation rendered the case more liable to post-operative peritonitis, than in a case in which little damage was done, saline fluid was left in the abdomen with the object of absorbing these micro-organisms quickly into the lymph stream; therefore the foot of the bed was raised on putting the patient to to bed to encourage the return of the peritoneal lymph stream. This tilting would be removed in 24 hours. Mr. Ryall called attention to the researches of Muscatello which proved that there was a definite lymph stream from the abdomen through the diaphragm into the mediastinal glands, that fluid was rapidly absorbed from the abdomen by this route, but the rapidity of the absorption was considerably increased by more or less inverting the patient.

It is satisfactory to state that three weeks after operation the patient was convalescent. Her progress never gave a moment's cause for anxiety.

ST. PETER'S HOSPITAL FOR STONE.

NEPHRO-LITHOTOMY FOLLOWING THE SUCCESSFUL APPLICATION OF THE X-RAYS.—Mr. SWINFORD EDWARDS

operated on a man, æt. about 25, who had suffered for some time past with typical symptoms of right renal colic. As the patient was a thin subject it was thought a good case for radiography, more especially as he himself was anxious to submit to this test before undergoing operation. Dr. Low, of Sinclair Gardens, was successful in obtaining a radiograph, which was seen to throw a distinct shadow on the right side. The shadow was a peculiar one, being long, in a vertical direction, thicker below and gradually tapering upwards. As there could be no doubt that the patient had a stone in his kidney, he willingly submitted to operation under ether. Mr. Edwards exposed the right kidney by the usual lumbar incision. After division of its capsule, it was easily turned out of the abdomen. The stone could be felt in the lower part of the renal pelvis; accordingly an incision was made along the outer convex border of the kidney towards its lower part, the finger was inserted, and several calculi felt; these were extracted with scoop and finger. The organ was carefully palpated for further calculi; at first ineffectually the incision was next closed with three silk sutures, but considering the shape and length of the shade thrown in the radiograph, Mr. Edwards thought that there must be other stones in the kidney, although not to be felt by palpation. He accordingly incised it in its upper part, and there came across a whole nest of small calculi, probably about 20 in number, most of them the size of a hemp seed. After the stones had been removed by a scoop this incision was sutured in the same manner as the first, and the kidney replaced in the abdomen, a large drainage tube having been inserted; the abdominal wound was sutured in layers. Mr. Edwards remarked that had it not been for the radiograph it was certain that the small stones in the upper part of the kidney would have escaped recognition, and thus the operation, which was apparently successful, would have been rendered ineffectual and incomplete. This was, he said, the second case he had had of successful radiography in renal calculus. The stones he had just removed he imagined to be composed of oxalate of lime; hence the good shadow obtained.

THE ARCTIC ZONE AS A HEALTH RESORT.

THE remarkable freedom of the air in the Arctic regions from all pathogenic micro-organisms, a freedom which, though possibly in a less degree, it shares with the air of mountains, has led to the suggestion of the establishment of sanatoria, in Spitzbergen, for instance. Scientific observers have remarked a curious freedom from diarrhoea, catarrh, intermittent fever, and other microbial diseases in places situated within the boreal regions. Incidentally, this fact appears to justify the suggestion that mere change of temperature is not *per se* sufficient to cause fever, apart from the introduction of pyrexia-producing organisms. Repeated exposure under very unfavourable conditions, it was noticed, never gave rise to the usual morbid reactions, but, on the other hand, it was remarked that even trifling wounds were unduly long in healing. Even the ordinary bacteria of water appear to be unable to exist under the trying conditions of Arctic life, so that imported germs would probably stand a poor chance of making fresh victims.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 15, 1899.

THE DECLINE OF SYPHILIS.

If further proof were wanting to show that syphilis as a disease is distinctly declining in this country, it is supplied by the definite, unqualified opinion on the subject expressed by Mr. Johnathan Hutchinson at the recent Congress in Brussels. Probably no one has had such ample opportunities for comparing and judging the effect of syphilis during the past thirty years as this well-known authority, and, therefore, great weight must of necessity be assigned to his observations. An American contemporary the *Inter-State Medical Journal* for October publishes a verbatim report of Mr. Hutchinson's speech at the Congress, and the report is of value, inasmuch as the opinions therein expressed appear to be new so far, indeed, as we are acquainted with Mr. Hutchinson's published works. Upon the subject of inherited syphilis, he states that during the last ten or fourteen years in England the deaths from this disease have been greatly reduced, in the proportion of from seventeen to twelve, and he scouts the idea that the inheritance of syphilis, as held, among others, by Fournier, is a means of reducing the stamina of the race. He holds to the belief that the third generation is not in the least hurt by the transmission of syphilis. Furthermore, the explicit statement is made that among the more educated classes in England syphilis is almost infinitely rare, "we scarcely ever see it at all," Mr. Hutchinson adds. Presumably, however, in this estimate, account is taken of the members of the 'educated classes,' "who, having found themselves to be the subjects of acquired syphilis, promptly betake

themselves to a continental health resort for systematic treatment. There is no doubt that for a good many years the advantages of adopting such a procedure "as this have been fully believed in by the "educated classes." The next point upon which Mr. Hutchinson has something to say is that of treatment, and we are glad to see that he expresses himself to the effect that there "is an improvement in the treatment which is likely to be productive of a great diminution in the prevalence of syphilis." He states that mercury is being used before secondary symptoms develop, "and in English practice we scarcely see," he adds, "a secondary stage at all—we suppress it altogether;" by this means much is done to prevent the manifestation of tertiary symptoms. So far as statistics are concerned the mortality ratio for syphilis in this country has fallen from 78 per million to 61 per million during the last fourteen years. Taken then, altogether, it is evident that the views of such an authority as Mr. Hutchinson entitles us to regard with some optimism the waning prevalence of syphilitic disease in this country. Although the statistics to which attention has been drawn may not be regarded as trustworthy, it is nevertheless significant that they should coincide with Mr. Hutchinson's experience. Again, it is quite possible that the experience of many surgeons during past years has tended to show a decline, both in the number of cases and in the severity of syphilis. It would be interesting, however, to learn whether this is really the fact, and whether any general agreement prevails in this regard; to judge merely from private patients would not be sufficient. Perhaps, indeed, the most valuable observations would be those based entirely upon hospital practice, since it is mainly among the lower orders that the dissemination of syphilis occurs. If it could be actually shown by inquiry that hospital patients suffering from syphilis are now much less numerous than used to be the case, a great point would be gained in the matter. At present, however, although no direct evidence is forthcoming, everything tends to indicate that syphilis as a disease has been latterly robbed of a good deal of its terrors, and is progressively on the decline.

DRUNK OR DYING ?

THE reproach to the medical profession conveyed in the above stereotyped newspaper heading is never absent from the public gaze for any long period of time. This recurrence of an error in medical diagnosis that is not only avoidable but also fraught with serious consequences suggests an analysis of the facts of the case with a view of lessening the scandal. Last week a tale of far too familiar type was unfolded before a South London coroner. A police constable found a man in a sitting posture in the front garden of a house in Bermondsey. Finding that this person could not speak or walk, and that he smelt of rum, the constable took him away on an ambulance to the police station. At the latter place the Assistant Divisional Surgeon saw the patient and pronounced

him drunk, on the ground that he smelt strongly of drink and looked like a drunken man, and that he seemed to understand what was said to him, although he could not speak. Although not mentioned definitely in the newspaper report from which our information is derived it may be inferred that the unfortunate man did not recover consciousness and was removed to the neighbouring workhouse infirmary, where he died four days after his being found insensible in the garden. When admitted to the infirmary the deceased was unconscious and paralysed on one side. After death a post-mortem examination revealed "a large blood clot" on the brain. It was pointed out to the jury by the Workhouse Medical Officer that the symptoms arising from apoplexy might readily be mistaken for those resulting from an excess of alcohol. That contention, it may be conceded, may hold true of a hurried or careless medical examination, but we venture to assert the great improbability, and in the vast majority of instances the impossibility, of any error of diagnosis if the latter be conducted carefully and systematically. Unconsciousness may be a sign of alcoholism, head injuries or cerebral disease, lunacy, and narcotic poisoning. There are, however, points of difference that would enable any competent investigator to make a differential diagnosis in ninety-nine cases out of a hundred. There are the many valuable signs and symptoms to be investigated, such as facial appearances the nature of the breathing, the depth of the unconsciousness, the state of the pupils, the signs of injury, the pulse, the temperature, and the occurrence of local paralyses and other nervous symptoms. The fallacy of the smell of drink is so ancient that one would imagine any medical man would in practice at once relegate it to the region of entirely subordinate and little trustworthy phenomena. Nowadays the standard of general intelligence demands from the police constable an acquaintance with the elementary distinctions between drunkenness and apoplexy. It is quite to be expected, however, that a mere layman will often be hopelessly at fault when called upon to reduce his theory to practice. But what is to be said of the error of medical men who hold official posts as police-surgeons, where they are from the nature of their position constantly called upon to decide as to the actual cause of unconsciousness in persons brought to police stations. It seems to us that the mistake must arise from a want of systematic inquiry into each individual case. Alcohol is the cause in perhaps ninety-nine cases out of a hundred, and it is assumed to be so in the hundredth, where a ruptured cerebral artery may be overlooked. But apart from actual errors of diagnosis, to which human nature must be always more or less liable, there are other important aspects of the case. It is surely a canon of scientific medicine that a drunken man is in a state of danger. The depressed circulation and the fall of temperature, not to mention other hardly less important factors, constitute elements of risk that may lead to immediate or to remote fatal results. Yet in spite of these well

recognised facts, it usually happens that when a man brought to a police-station has been pronounced drunk, either with or without medical authority, he is lodged in a cell and left, either with infrequent supervision or he is not visited at all. The simple rule of never leaving an unconscious person alone is paramount in all well-regulated nursing organisations, and there is no apparent reason why police cells should be excepted from the operation of so reasonable and elementary a precaution. A skilled attendant left by the side of a man suffering from unrecognised apoplexy would soon become aware of the fact, and some provision of this kind, at any rate in the larger police-stations, would prevent the recurrence of the discreditable scandal of a confusion between drunk and dying persons. After the lapse of a few hours the effects of alcohol pass away, but during the time of alcoholic unconsciousness the sufferer requires attention as to warmth, position, and other circumstances of his unhappy state. By the observance of a few simple rules in all doubtful cases the police would do much towards lessening their own responsibility, and at the same time would increase the respect and confidence of the public. The need of more careful and systematic investigation by police surgeons has been already hinted at, and we are sure the suggestion will be received in the spirit of kindly sympathy with a most difficult task that has inspired the present article. By a combination of these two official branches of police administration, it may be hoped that the occurrence of "Drunk or Dying" cases will be reduced to the extremest tenuity possible within the unavoidable margin of human error. From an academic point of view a thorough grounding of the medical student in the subject of unconsciousness would be of infinitely more practical use to him in his professional life than much of the high standard examination lumber with which he is now overweighted in the interests of aspiring examiners and competing colleges.

LUNACY IN IRELAND.

We print in our Supplement of this day an abstract of the latest report of the Inspectors of Lunatic Asylums for Ireland, and as we have already devoted so much space to discussion of the subject, it is impossible for us to attempt to epitomise it at length. The controversy starts from the admitted fact that the number of persons charged against the taxpayer has, of late years, enormously increased in Ireland, as in every other part of the United Kingdom, and *pari passu* the outlay for their accommodation and maintenance has come very near to breaking strain. As to the cause of this there are two opinions: (a) That held by the official party, who say that, in consequence of the increased pressure of life conditions, insanity has actually largely increased, and of course must be provided for at any cost. (b) That held by the sceptics, who assert that the increase is in great measure apparent, and that it arises from mistaken legislation and misconceived administration, and

might be met by other expedients than the monstrous expansion of public asylums and of the administrative staffs. In both of these views there is, we think an element of truth. In other places which are outside the influences which dominate the question in Ireland, a steady and material increase in lunacy has been recognised of late years, and it may be reasonably be supposed that the causes have been made more potent by the impulsive character of the people and the incidence of the acrimonious political agitations of the past twenty years. But, even so, the rapidity and amount of the increase in Ireland cannot be accounted for, and we are driven to the conclusion that those who hold the second opinion above enunciated are right. Apart from the ordinary fluctuations in the prevalence of lunacy there are special ruling influences. First there is the supposition that the people who were wont to keep their insane relatives at home, where they were never heard of, have of late years learned that, by a very simple process they can get rid of them at the expense of the taxpayer. Second, that the Boards of Guardians have not been slow to learn the same lesson, and have been glad to pass over their workhouse lunatics from their own establishments, where they have been supported by the rates, to the asylums, supported by the grand juries and the Government. We believe that the Dangerous Lunatics Acts of 1867 and 1875 are at the bottom of it all; for the committal of lunatics they are as speedy and convenient as the ordinary Lunacy Acts are complicated and troublesome. It is only necessary for a farmer who wishes to relieve himself of the maintenance of an idiot boy to send for the nearest policeman and asseverate that the boy is obstreperous and dangerous, whereupon the policeman charges the patient at the next petty sessions, before two magistrates, for being in a condition to commit a felony. The nearest dispensary doctor is called in, and upon his certificate, that the report of the policeman is true, the boy is sent off to the asylum. In this way a considerable section of the humbler population is being transferred from their own homes, where they cost nothing, and from the workhouses, where they cost very little, to the asylums where they cost a great deal. Upon this and other grounds the advocates of the "apparent lunacy" theory maintain that Irish asylums have been filled up with individuals who, twenty years ago, would have been working in the fields, and that their incarceration at the public expense is being made the excuse for a perfectly amazing waste of money upon architects and builders for the enlargement of old asylums and the building of new ones. Without being prepared to pin our faith to this, we are certainly ready to say that the outlay for these purposes has been, for years, monstrous and intolerable, and that a stay ought to be put upon the erection of palatial buildings and luxurious appanages until the subject is investigated by those capable of forming a just opinion.

Notes on Current Topics.

The Joint-Stock Consultation Club.

THE proposal to establish in Birmingham a sort of medical consultation club in which every member will be entitled to the services of a Consultant (save the mark) for the humble fee of half a guinea, does not appear to make progress considering that it is many months since it was promulgated, and the scheme has lain dormant. The Hospital Saturday Fund has now taken up the idea, and hopes to attain popularity thereby. We shall not expend space on urging upon the practitioners who may be disposed to act as consultants on these terms, that, in doing so they lower their professional position. They would, probably, be quite content to do so if it pays. But we may suggest to the public that the consultant whom they obtain for 10s. 6d. is in no respect a better adviser than the general practitioner whom he is called to supplement. No specialist who has much pressure on his time will give the portion of it necessary for a competent consultation diagnosis for any such sum, and the only alternative the joint stock consultant could adopt would be to run the patients off as in a fourpenny dispensary at five minutes a piece. We should suppose that any really sick person who has undergone such a consultation will conclude that he does not desire any more of the article. There is, in fact, no such thing as a second or third class consultant. Any aspiring practitioner may assume the name but, unless he is a recognised expert in his own specialty the general practitioner will not want his help, and the patient will not be content to pay for it.

Tame Deer Hunting.

SINCE the famous speech with which early in this year the Duke of Portland favoured the counsels of the anti-vivisectionists in St. James's Hall the scientific world has waited, in vain for further information as to certain of his Grace's views upon sport. No such authentic statement has been forthcoming but the hunting of tame deer is still being carried on merrily by the Queen's Buckhounds. As master of the so-called sport provided by the royal pack the Duke has a somewhat formidable list of casualties to justify in support of his proposition that this kind of hunting is good for the deer. Last week the season was opened by uncarting a quarry at Salt Hill. The incidents of the chase that followed, at least, if they be as reported in the newspaper, are calculated to wring tears from any individual who is not blinded by the fetish of sport towards the claims of kind-hearted humanity and conscience. The deer's first exploit was to join a flock of sheep, and afterwards to lie down by the side of a haystack. Later in the run the unfortunate animal took refuge with a herd of cows, and followed one of the latter into a cowshed, whence it was driven back to the hounds by a cowman. The quarry then swam the Thames, and was reported to have been at length captured in the forest. The usual record of wounds by barbed wire is wanting,

possibly because the reporter thinks that side of the subject has lost its novelty. Why cannot the anti-vivisectionists try and put a stop to this degraded cruelty perpetrated in the sacred name of sport. The Queen's Buckhounds are carried on for the behoof of as motley a concourse of sportsmen as ever disgraced a hunting field.

Bad Meat for British Troops.

THE history of the part played by the army contractor in the fate of nations, would furnish pregnant reading to the student of human nature. If current rumours have any foundation in fact the service contracts are more or less honeycombed with secret commission and other abuses. At the same time it is only right to say that many schemes have been devised and put into practice by Government with a view of putting an end to the shifty cunning of a dishonest tribe. A disgraceful attempt to palm off a cargo of bad meat was last week happily foiled. The troopship *Arawa* was about to sail for the Cape, when it was discovered that the supply of meat on board was in a bad condition. The embarkation officer inspected the stuff with the result that he ordered the whole consignment to be turned out on the quay. A fresh supply was speedily forthcoming, and the ship was despatched after a delay of some twenty-four hours. Now, this meat was taken aboard at Plymouth before the ship sailed to the embarkation point at Southampton. It consisted of about 15,000 lbs. of beef and mutton, both foreign and colonial. When turned out at Southampton it was unfit for human food. In the official inquiry that must follow the public will demand that the responsibility of passing the condemned meat be fixed upon the proper persons. A scandal of this kind demonstrates the rottenness of Government service supervision of contracts. If the *Arawa* had been allowed to sail it is likely that the troops on board would have been exposed to danger not less fatal than those contingent upon the campaign to which they are now speeding. The question now is, who is to be hanged for that bad meat?

Measles in General Hospitals.

THE management of Guy's Hospital can hardly be congratulated on some of the incidents connected with their institution that attain publicity from time to time through the medium of the Coroner's court. Last week, an inquest was held on the body of a child who had been discharged from the hospital mentioned because of the development of measles. The mother took the child home where it afterwards died, and a medical man refused a death certificate. The mother, however, obtained the requisite document from the House Physician under whose care deceased had been while in the wards. His right to sign was called in question by the Coroner, who commented severely on the incident. To those who have studied the facts of death certification in this country, this occurrence will cause little surprise, as the whole system is so riddled with inconsistencies and fallacies as to be in not a few instances worthless. That the

residents in hospital know little and care less about the interests of outside practitioners is notorious. The harm they do in that way is incalculable, they are careless of what has been said or done by other medical men to patients before coming to hospital, and they never trouble to inquire as to the suitability of applicants for relief. In these particulars they simply follow the lead of the hospital authorities, by whom the existence of a medical profession outside is simply ignored. It is sad to think how one day many of these careless and jovial house-surgeons and house-physicians will find themselves heavily handicapped in the struggle for existence by the medical charities. By the way why has not this tolerably wealthy charity of Guy's Hospital an isolation ward whither a child developing measles could be conveyed?

Further Definitions of Professional Secrecy.

FOR some inscrutable reason the doctrine of professional secrecy *à l'outrance* has always received support and legal endorsement in France, and while we fully concur in the general principle of the inviolability of knowledge acquired in the exercise of professional functions, it is obvious that there must be limits to the obligation. It is no part of the duty of the medical man to denounce crime, but he must be careful, on the other hand, not to throw his professional mantle over the crime and the criminal. Some recent decisions of the French Courts extend and define the doctrine. One of them formally declares that a medical man may not reveal to a life insurance company any details concerning the life-history of a person, whom he has been requested to examine, which have become known to him in his capacity as medical adviser to the examinee. Another decision declares it to be a violation of professional secrecy when a medical man delivers a certificate to a third person stating the exact injury received by a workman who is bringing an action for damages. At first sight these decisions may appear somewhat extraordinary, but on scrutinising them more closely it will be seen that they only embody principles which must receive the approbation of every conscientious practitioner. They simply amount to the statement that information acquired by the doctor in the course of his professional ministrations cannot be utilised for any other purpose than the treatment of his patient, indeed to do otherwise would, even in this country, expose the careless or unscrupulous practitioner to the risk of an action for damages for breach of confidence provided the plaintiff could allege specific injury on which to base his claim.

Municipal Crematoria.

THE progress of cremation is shown, if further proof were wanted, by the growing feeling in favour of the establishment of municipal crematoria. The city of Hull has just led the way in this regard. Last week, with much ceremony, the foundation-stone of a municipal crematorium was laid by a member of the corporation. We also understand that the

Sanitary Committee of the Court of Common Council of the City of London have carried a recommendation by which the corporation have agreed to promote a Bill next session to provide powers for the erection of a crematorium at Ilford cemetery. At present the nearest crematorium for Londoners is that at Woking, but for all save those whose means are fairly ample, the cost of the process is prohibitive. In order to encourage the masses to adopt cremation clearly the first step to be taken in the matter is to arrange a scale of charges which shall be "popular"—that is to say, within the means of all persons who have any means at all. The opportunity of so doing is now about to be afforded by the erection of municipal crematoria. It would be quite within the power of the municipal authorities to provide facilities for cremation at a figure which would be very moderate, and yet, at the same time, cover all expenses. Moreover, so far as large towns are concerned crematoria may be made the means of saving much expense now attaching to the disposal of the unclaimed dead. But these are matters of the future, and do not concern the question of cremation just yet. Nevertheless, we believe that the time will come when the necessity will be shown to exist for municipal crematoria throughout all the large towns in the kingdom.

Dentistry for Women.

WE should not have thought that dentistry would have commended itself much to women as a professional occupation. But a woman's paper suggests that it would prove to be a lucrative profession for women, and this opinion appears to be based upon the fact that there is at the present time a woman who is successfully practising as a dentist in London. Of course, the old argument will not fail to operate here, that "one swallow does not make a summer," and whether women would or would not prove to be good dentists could only be determined by actual experience. Meanwhile, there would probably be few who would care to make the experiment.

Praiseworthy Generosity.

WE understand that a crisis in the financial affairs has occurred in connection with the Norfolk and Norwich Hospital. This gloomy condition of things has been mainly brought about by the serious decline in annual subscriptions, the vertebral column of every charitable institution. The result of this lack of support has compelled the governors to consider the necessity of closing a portion of the hospital, a step which, if carried out, as the *Eastern Daily Press* very rightly observes, would be a reflection upon the whole district. Under the circumstances, therefore, some special local county effort is clearly required to avert so undesirable a contingency, and we are glad to see that the philanthropic ball has been set rolling in this regard by some well-known Norwich residents. For example, Messrs. J. and J. Colman have doubled their annual subscription of fifty guineas; Mr. S. G. Buxton increases his annual subscription to £100; Mr. J. N. Gurney

increases his to £50; Mr. H. G. Barclay to £20. and Messrs. Boulton and Paul to ten guineas. These are praiseworthy examples of practical philanthropy which can scarcely fail to have an indirect influence for good. All that is wanted now for the Norfolk and Norwich Hospital is for the other annual subscribers to follow suit and thus help to place the institution upon a sound financial basis. We should hope that this consummation will be attained, for the charity in question has a long and honourable record, and for this reason should be one of the first of those to secure the cordial support of town and country Norfolk men and women.

Bicycle Knee.

CONSIDERING what an important part is played by the knee joint and adjacent structures in propelling the bicycle it is rather a matter for surprise that attention has not been called to the troubles of which it may be the seat as the result of too protracted or too severe a strain in riding. Numerous cases have been brought to our notice of incapacity for this form of exercise occasioned by the pain to which it gives rise. This pain presents several characteristic features. It occurs in only one knee, and, as a rule, is not felt in walking. Moreover, it often does not supervene at the beginning of a ride, but comes on gradually, ultimately attaining an intensity which may absolutely prevent the rider from continuing his excursion and oblige him to adopt some other method of locomotion for the purpose of regaining his domicile. One feature appears to be common to all these cases, namely, that the pain is exterior to the joint, and the swelling, if present, is limited to the sheaths of the tendons which run past the joint or to the insertions of muscles in that neighbourhood. It is not associated with manifestations in other parts of the body which would justify the diagnosis of rheumatism, and it occurs in persons who are not, as far as one can judge, the subjects of the rheumatic diathesis. In most instances abstinence from the use of the cycle suffices to bring about a cure, but in some, the minority, it displays a tendency to recur under stress, and in this event it constitutes a formal contra-indication for more than very moderate indulgence in this pastime. It is due, no doubt, to immoderate strain of the extensor muscles, which are mainly concerned in driving the machine, and is strictly akin to the pain, &c., felt when the muscles of the forearm are subjected to unwonted strain. In most of the cases that have come under our notice the primary cause would seem to be too high a gear, which throws an exaggerated strain on the muscles, or a saddle placed too low down so that the flexion of the knee is unnecessarily increased. In the absence of either of these causes hill-climbing has been known to bring on an attack, but in reality this amounts to the same thing as too high a gear. When we speak of a gear as too high we mean, of course, too high for all-round work, for it is evident that a gear which may be suitable enough for the home counties would be quite unsuitable for Devonshire or the Lake District. It is necessary to

put cyclists on their guard against a complication which may debar them from their favourite pastime, and they should learn to be warned by the earlier admonitions without waiting for absolute incapacity to supervene.

The Power of the Imagination.

THE influence of the imagination is a factor with which physicians have to reckon very largely and in the minor ailments of life, at any rate, the most successful practitioner is he who possesses the faculty of inspiring confidence in himself to begin with, and then in the treatment he advises. A recent number of the *Psychological Review* relates an interesting experiment made by Mr. Slosson with the view of demonstrating how easily this faculty can be called into play. In the course of a popular lecture he presented to his audience a bottle containing distilled water, which he uncorked with elaborate precautions and then, watch in hand, he asked those present to indicate the exact moment at which the peculiar odour was perceived by them. Within fifteen seconds those immediately in front of him held up their hands, and within forty seconds those at the other end of the room declared that they distinctly perceived the odour. There was an obstinate minority, largely composed of men, who stoutly declared their inability to detect any odour, but Mr. Slosson believes that many more would have given in had he not been compelled to bring the experiment to a close within a minute of opening the bottle, several persons in the front rank finding the odour so powerful that they hastily quitted the lecture room. It would have been interesting to know the attitude of the audience on learning the liberty that had been taken with their imaginations, but on this point unfortunately the report is silent.

A Curious Case.

THE last number of the *Therapeutic Gazette* contains the account of a very curious case, so curious indeed that we should like further evidence before accepting it as duly authenticated. Dr. Eckman, of Philadelphia, was called to a woman, æt. 25, who was very ill, and in whom, on examination, a distinct mass was felt below, and to the right of the umbilicus. This appeared to be continuous with the uterus which was much displaced upwards, and was barely accessible. As she improved somewhat, nothing was done until a month later when he was again called to the patient who then complained of an inflamed and tender umbilicus. This was poulticed, and after a time a solid something projected from the navel which proved to be a No. 9 linen catheter. On questioning the patient he elicited from her that three months previously, (three weeks before his first seeing her), her physician had attempted to bring about a miscarriage by introducing a catheter into the uterus, directing her to return on the following day to have it removed. This she was prevented from doing for some days, and when she did so the physician was unable to find the catheter. She subsequently developed alarming symptoms, and

became so ill that her life was despaired of when Dr. Eckman was first summoned to her. We share with Dr. Eckman a difficulty in explaining the route taken by the instrument, which could hardly have perforated the uterus in the first instance.

Physical Competitive Examinations.

In an exhaustive letter to a medical contemporary, Mr. Henry Cayley discusses the physical tests for admission to the Public Services, and in the course of his remarks he says that, "so far as the interests or welfare of the candidates are concerned, it is probably, quite immaterial whether they are submitted to physical examination immediately before or after the competitive," and he proceeds to argue against physical examination in advance, on the ground that the condition of health of candidates must be established at the exact time of their admission, and, if preliminary physical examination were the rule, that condition might have materially altered during the period of study. While fully agreeing to this contention, we are unable to see why it should be impossible to submit a candidate to preliminary physical examination at any reasonable period before his examination, and also to a final corroborative test after he has passed the competitive examination, especially if he is willing to pay for the additional privilege. Mr. Cayley says that "no official Medical Board could give any more decisive or binding opinion than that given by a private medical man," but it is manifest that no private opinion, by whomsoever it may be delivered, can have more than a moral influence on the Army authorities or can, in any way, protect the candidate against subsequent ostracism by the Medical Board. Again he asks:—"If one were rejected on the second occasion who had been previously pronounced fit, what a flood of grievances this would give rise to." At the first physical examination all obvious physical disqualifications would be revealed, such as narrowness of chest girth or high astigmatism, and an official record thereof would be preserved until, if ever, the candidates came up for final physical examination, when nothing would remain to be tested save the conformity of the second examination with that of the first. Moreover, in this matter, we strongly suspect that preliminary physical examination is resisted by the authorities because they object to the trouble of such an examination for each candidate, and we, also, apprehend that physical fault is made an excuse for disqualifying candidates who do not appear to the Medical Boards to be up to standard in respect of social or regimental requirements.

Ventilation of Railway Carriages.

THE plan of ventilating railway carriages *via* the open window obviously suggests many objections. Not only is the air laden with grimy dust, but the air surrounding a train on the road is stated to contain 1.8 to 2.28 per cent. of carbonic acid gas. A German railway engineer makes a valuable suggestion in this connection, he proposes, in fact, that the air should

be conveyed to the carriages by conduits starting from the front of the locomotive, so that it would be free from dust and deleterious impurities. This plan does not present any technical difficulties of moment, and it would be easy to warm the incoming air on its passage through, or along, the engine, thus obviating the necessity for other means of keeping up the temperature during the cold season. We submit this suggestion to the managers of our railway companies, coupled with the expression of a hope that they may see fit to give it a trial.

The First Epileptic Home in England.

THE founder, the late Mr. Henry Cox, did not live to see the full fruit of his munificence; but an account of ten years pioneer work has just been published which contributes a tribute to his memory of the most gratifying kind. The nucleus of the work was begun in Manor House, Maghull, an old country house outside Liverpool. The evolution of the scheme is most interesting reading; the famous colony at Bielefeld, in Germany, was first visited; but though much pleased with it, "the committee felt that they could not hope in England, even if it were desirable, to imitate the plan pursued at Bielefeld, whereby a large staff of nurses and assistants gave their services voluntarily, with no hope of gain." They recognised the noble ideals of such men and women, but felt that "our nurses and attendants would require a 'living' wage instead of mere sustenance here, and the hope of a reward hereafter." They count also on no small measure of devotion from paid labour, and they are right. Some with good hearts and minds must have pay, for affluence or even a modest competence is not their lot. It was necessary that each patient should pay, and they were graded in three classes—paying two guineas, one guinea, and seven-and-six a week respectively, the profits from the first and second class to meet the deficiencies of the third. The institution had prospered as it deserved to do, and another building has been erected. The number of patients has increased from 20 the first year to 120 last year. We would specially recommend a careful perusal of this report to all interested in the welfare of the epileptic. It gives interesting information regarding the various occupations of the patients, with illustrative views of lawn-mowing, milking, harvesting, &c., the medical results, hints to parents and guardians of epileptics, &c.

Practice on Single Qualifications.

IN the correspondence columns of a medical contemporary we notice the statement that the licence of the London College of Physicians "is a qualification under the Medical Acts, and is recognised by the (English) Local Government Board, and its possessor would thus, if registered, be entitled to hold a Poor-law appointment." This statement is, no doubt unintentionally, entirely misleading, and, if allowed to pass, might place other colleges in a false position. Under the third section of the Medical Act of 1886 no single qualification entitles a person

to go on the Register. It must be combined with a qualification in the correlative subjects derived from another body, or, in the case of a university, from itself. In fact, the registered diplomas must represent separate qualifications in medicine, surgery, and midwifery, and no single qualification fulfils this requirement, nor can any one go on the Register in respect of such single qualification. But any one possessing a single qualification can have it entered on the Register if he has already presented a diploma in the correlative subject, and, *pro tanto*, the Local Government Board will recognise such entry when complete, but not otherwise. It is, therefore, not the whole truth to say that any single diploma qualifies for a public position.

Voluntary Notification.

WE note that, at Norwich, the municipality has agreed that a fee shall be paid for the voluntary notification of phthisis, and that Manchester is being urged to adopt the same arrangement, but as to who is to notify and to receive the fee we are not informed. From a professional aspect this is a very important point. Every one will be delighted if the public will take upon themselves the duty of notifying this and all other diseases, but the proposal that a medical practitioner shall surreptitiously communicate to the public authorities the information which he may obtain in private practice, and shall accept a fee for doing so, is a different matter. When the Compulsory Notification Acts were in progress, we were told that no breach of professional confidence was involved inasmuch as the law would compel all practitioners alike to be guilty of that breach. This is not the case under voluntary notification, and we do not hesitate to say that it is open to the gravest question that a practitioner, being under no legal compulsion whatever, shall be encouraged to sell the information which he obtains as a private medical adviser to the public authorities without the complete assent of the patients who are interested. If such a principle be admitted in the case of phthisis, why not in the case of syphilis, or any other disease?

The Certificate Question at the Cardiff Infirmary.

WE referred a few weeks since to the question which had been raised at the Cardiff Infirmary as to the destination of the fees charged for certificates given by the medical officers of the infirmary to patients of that institution. A committee was appointed to inquire into the practice which had come to the front on a motion to the effect that all such fees should be placed to the credit of the hospital funds. The decision just arrived at is that in future no fees whatever shall be charged for such certificates, and this, we believe, is in accordance with the general practice at similar institutions elsewhere. It is obvious, however, that there must be a limit to the giving of such certificates, for while they may properly be delivered without fee when they are to be used for the purpose of obtaining sick pay, no such

indulgence is called for when the certificate is intended for the purpose of bringing legal proceedings, civil or criminal. In such cases the medical officer is entitled to refuse to provide evidence unless summoned in the usual way and paid the usual fees.

Chrysarobin a Specific for Warts.

DR. G. M. FITZ calls attention to the excellent results which are obtained in the treatment of warts by solutions of chrysarobin. He first pares down the wart until there is rather profuse bleeding, and then applies a ten-per-cent. solution of the drug, the vehicle being either ether or the ordinary gutta-percha solution. As a matter of fact, chrysarobin is by no means the only effectual means of dealing with these often refractory conditions of epithelial hypertrophy. The essential part of the treatment is unquestionably the removal of the thickened epithelium. When this has been done the application of chromic acid or a collodion solution of salicylic acid will, in most cases, cause the disappearance of the growths within a few days.

The Prevalence of Typhoid Fever in the County of Durham.

THE County Medical Officer of Health for Durham, in his recent quarterly report, pointed out that the County of Durham has had for some years past a higher death-rate from typhoid fever than any other county in England and Wales. Dr. Eustace Hill states that some of the most serious epidemics of the disease which have occurred were probably due to pollution of the water supply. But these outbreaks were not sufficient to account for its marked prevalence and high mortality in this county year after year. The matter has claimed the attention of the Durham County Council, and a decision has been arrived at to invite the Local Government Board to institute an inquiry.

The Belfast Royal Victoria Hospital and Professor Cuming.

AT a meeting of the Committee of this hospital, on the 9th inst., the President of the Queen's College proposed a resolution of regret on the death of the late Professor Cuming, and delivered an eloquent eulogy upon his personal and professional character, and the resolution, needless to say, was adopted by acclamation. A letter was then read from the Right Hon. W. J. Pirrie, presenting to the hospital the sum of £7,000 on condition that one of the wards shall be named after the deceased Professor, a proviso which, of course, was at once accepted. The Committee of the hospital has now in hand nearly £76,000 towards its completion and endowment, and it is anticipated that numerous endowments have yet to come in.

A Skin Hospital for Dublin.

IN a previous issue we referred to the effort made to organise in Dublin a special hospital for diseases of the skin, we have reason to believe that the scheme has now sufficiently progressed to allow of the out-

patients' department being already available for use. The hospital is to be non-sectarian. Dr. C. M. O'Brien, who is an old Middlesex Hospital man, and at present an examiner in the Apothecaries' Hall, Ireland, and formerly senior member of the resident staff of one of the Dublin hospitals, has been appointed physician. Mr. G. B. White, who is also an examiner, and known as a contributor to our pages, has been appointed surgeon.

Strabismus a Sign of Neuropathic Inheritance.

THERE is a popular idea that a squint is associated with a more or less marked mental peculiarity, and this view is supported by Dr. de Micas, who has found that the immediate and collateral ancestors of persons who squint comprise many with neuropathic antecedents. Of course, any ametropic child may squint, but if, with the error of refraction, is associated this neuropathic predisposition, a squint is the rule. Even in the absence of any error of refraction, the children of neuropathic parents appear to be peculiarly liable to this deformity, which, indeed, may be the outward and visible sign of the morbid inheritance.

DR. NESTOR TIRARD, Professor of Materia Medica and Therapeutics in King's College, London, will deliver a course of three lectures on Pharmacy and the New Pharmacopœia at the Society of Apothecaries on Tuesday next and the two Tuesdays following at four o'clock. Members of the medical profession will be admitted free on presentation of their cards.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

A FIGHTING DOCTOR FINED.—One of the most respected physicians in Perth, one day last week, happened to be out on his bicycle, and to have occasion to pass a blacksmith standing on the road. He rang his bell to no purpose, and as he passed close to the fellow was knocked off his cycle by what he averred later in Court to be an intentional protrusion of an elbow. On picking himself up and remonstrating, the blacksmith showed an intention of fighting, and the doctor, wishing as he explained, to get the first exchange, got in the first blow, drawing blood. The doctor may have been hasty, but the other surely was most to blame. However, it was the blacksmith who got off scot-free in Court and the doctor who was fined one pound.

EDINBURGH MEDICAL STUDENTS START FOR THE TRANSVAAL.—On Saturday night a party of medical students left Edinburgh for London, purposing to go out to South Africa under the leadership of Dr. Neethling of Bradford, to act as an ambulance party in aid of the Boers. The scheme is said to have originated in the South African Union in Edinburgh, and is suggested to be financed by Sir James Sivewright. The men are all Cape Colony born and bred, and British subjects, though almost all of Dutch extraction.

FACULTY OF PHYSICIANS AND SURGEONS.—At a meeting of the Fellows of the Faculty of Physicians and Surgeons, held on the 6th inst., the following office bearers were duly appointed for the ensuing year:—President: Dr. H. C. Cameron. Visitor: Dr. James Finlayson. Councillors: The President ex-officio, also as representative to the General Medical Council—

the Visitor ex-officio; the Treasurer ex-officio; Dr. John Glaisler, Dr. Bruce Goff, Dr. Robert Perry, Dr. D. N. Knox, Dr. John Barlow, Dr. J. Lindsay Steven, Dr. W. L. Reid. Treasurer: Dr. James D. MacLaren. Hon. Librarian: Dr. James Finlayson. Secretary and Librarian: Dr. Alexander Duncan. The usual examiners, both for the Fellowship and for the License were appointed.

SEQUEL TO GLASGOW UNIVERSITY RECTORIAL ELECTION.—On the day of the election, the Students' Representative Council lodged a protest with the senators regarding the action on the part of Professor George Gilbert Ramsay during the election. The names of three students were tendered as having being forcibly interfered with, in fact assaulted by the professor, while keeping the door on behalf of the Liberal party. The students were requested to meet Professor Ramsay-Stewart and the Principal on a certain day. They accordingly presented themselves, when they discovered that no official member of the Representative Council, by whom the protest was lodged, had been invited to attend. Under the circumstances, the students summoned to appear declined to discuss the matter until such an official member was requested to attend and was present. The secretary of the Students' Representative Council was then sent for, with the result that Professor G. G. Ramsay agreed to apologise individually to the three students concerned, and also to the students generally through the secretary of the S.R.C.

PROFESSOR SIR WILLIAM T. GAIRDNER, K.C.B.—The worthy and gifted Professor of Practice of Physic, as he likes to call it, has just entered upon his seventy-sixth year of age and his thirty-eighth session as Professor of Practice of Medicine in the University of Glasgow. He was a graduate of Edinburgh University as long ago as 1845, and was in 1863 appointed Medical Officer of Health for the City of Glasgow, being the first officer of the kind, which post he held for eleven years, when he resigned and his assistant, Dr. J. B. Russell, was appointed to succeed him. Sir William holds many honorary titles, and is Physician-in-Ordinary to the Queen for Scotland. On December 25th, 1856, he was one of four medical men who were present at the post-mortem examination on the body of Hugh Miller, and he is and always has been a great favourite of the students, by whom he is known as W. T. G.

MEDICAL SOCIETY OF LONDON.

LAST Monday's meeting was devoted to clinical cases. Dr. Cautley showed two cases, one a curious one of aphasia and agraphia in a man, æt. 71, in process of cure, which he attributed to a small hæmorrhage in the second and third frontal convolutions pressing on the centres for speech and writing. (2) A lad with a well-marked systolic thrill and bruit perceptible over the base of the heart as well as in the neck and back, which he thought must be due to a congenital defect of the aortic valves, especially as there was hypertrophy of the left ventricle.

In the remarks that followed, however, arguments were advanced in favour of the lesion being of the nature of a persistent ductus arteriosus, though the absence of cyanosis was against it. The lad's health was good, and though the bruit was very loud it did not appear to involve much obstruction.

Dr. Ewart showed an Italian, who came with symptoms which at first sight suggested that he was suffering from Addison's disease. There was great loss of flesh, weakness, vomiting and pigmentation of the skin and nails; but on further consideration the pigmentation was found to be of old standing, and probably due to his occupation as an asphalt-layer. His liver and spleen were much enlarged, and there was an increase in the white corpuscles and eosinophiles, with a decrease in the red corpuscles. There was no history of malaria, so that, although the idea of its being a case of Addison's disease must be dismissed, the diagnosis remains obscure.

Dr. Ewart also showed an interesting patient, in whom an attack of persistent lockjaw was relieved by a deep incision into an inflamed portion of gum, of which Dr.

Kingscote gave two other examples under his own observation.

Mr. H. L. Barnard showed a man, æt. 20, with an enormous *hernia cerebri*, which had followed removal of a large piece of skull done to relieve serious pressure symptoms of four years' standing. Great relief of the symptoms followed, though the tumour could not be reached, and its nature is still obscure.

Mr. Wallis showed three cases, two of Pott's fracture, and one of fractured tibia, in which he had secured coaptation of the fragments by wiring, with excellent results.

Lastly, Mr. Morgan showed a young man who, after treatment of a large axillary abscess, suffered occasionally from solid oedema of the arm and forearm, the hand being exempt, due presumably to blockage of the lymphatics.

MEDICAL ATTENDANCE GRATIS AT THE R.A.M.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—A former patient of mine, a student at the Royal Academy of Music, tells me that she will no longer have occasion to consult me because a certain medical man has volunteered to attend the pupils of the Academy gratis.

Now, the pupils of the Royal Academy of Music are presumably persons in fairly good circumstances; in any event, they are scarcely persons who can have any claim to gratuitous medical treatment, and it would be interesting to know what motives could have prompted this medical pseudo-philanthropist to place his services gratuitously at their disposal. Possibly some of your readers may be able to throw some light on conduct which has excited mixed feelings in my bosom.

I am, Sir, yours truly,

A GENERAL PRACTITIONER.

Literature.

McKEOWN ON "UNRIPE CATARACT." (a)

Dr. McKEOWN is well known in connection with the treatment of so-called "unripe" cataract. In the preface he informs us that he brought the matter before the profession in 1884, and from that time up to the present his injection and irrigation method of treatment of immature cataract has been constantly followed in his practice. He has now resorted to it in about 700 cases of various kinds. The present volume is the outcome of the experience which he has gained in this special subject. To those who are desirous of learning the latest details of the author's method the work will prove mightily useful. But the treatise is really a monograph upon the subject of cataract, and as such it may be usefully perused by all ophthalmic surgeons. After discussing the classification of the disease the author proceeds to describe in detail the methods of operation. It would rather seem that this chapter had been placed in the wrong position; presumably, it should have followed that on "Operations for Cataract." The author points to six methods of dealing with the cornea. Three of these are preliminary:—(1) The needle operation; (2) Foster's artificial maturation; (3) the introduction of a liquid inside the capsule of the lens immediately before the stage of capsulotomy, and three which are applicable after expulsion of the body of the lens; (4) By pressure and friction on the outer surface of the eye whether by spoon or finger, and directly on the eye, or on the eye through the medium of the lids; (5) scooping out by a scoop introduced into the eye; (6) the

force and disintegrating action of liquid introduced into the eye. Dr. McKeown has not much to say in favour of Foster's method, and in any case he believes it to be of limited application. In regard to the introduction of liquid into the capsule at the time of operation he claims that it renders transparent substance opaque, breaks up striated, flaky, mother-of-pearl cornea, and separates cortical substance from the capsule. These, of course, are great advantages in comparison with other methods. So far as the irrigation method is concerned, after the lens has been expelled, the author lays down that the liquid presses the posterior capsule of the lens backwards, usually causes the cut and torn capsule to come forwards, and to flap about according to the direction and force of the stream, and reaches every part of the interior of the capsule, searches every corner for cortical remains, whether large or small, concealed or exposed, opaque or transparent. The author further points out that he has had experience of three combinations of methods, viz:—(1) Combination of injection by fine hollow needle and massage; (2) combination of scooping with irrigation; (3) combination of irrigation with massage. A list is also subjoined of cortical cataracts, and details given of the methods of treating them which in the author's hands have proved to be most beneficial. A useful chapter follows upon the subject of preparation for operation. Here we notice that Dr. McKeown pledges his faith in chinocol as an antiseptic agent, so much so, that he new uses no other. He significantly remarks that if a solution of perchloride of mercury be used for washing out the anterior chamber, the cornea is apt to become opaque, with disastrous effects to the vision, whereas he adds that he has several times irrigated the anterior chamber in cases of severe suppurative keratitis, with a solution of chinocol, without any opacity of the cornea being caused. The other chapters in the volume are "Detailed Description of Apparatus for Injection and Irrigation and Method of Use," "Operations for Cataract," "Post-Operative Incidents and Treatment," and a "Statement of Cases." Two appendices also are added, in one of which is discussed the ever verdant question of iridectomy in cataract operations. Whether or not Dr. McKeown's methods of the treatment of cortical cataract are destined to come into favour among ophthalmic surgeons, cannot be determined at present. If it were always possible to extract a cataract in its capsule, there would be no need for surgeons to concern themselves about the cornea, but since it is impossible to deny that the operation of cataract extraction is often seriously complicated when there is soft lens matter to deal with, it is well to know that the method of treatment in such cases elaborated by Dr. McKeown holds out prospects of the attainment of good results.

KINGSCOTE'S ASTHMA. (a)

THE author of this work is kind enough to inform us in his preface that it is not to be considered an exhaustive treatise on asthma. The caution is not necessary, for there is no possibility of such a mistake being made. The book is divided into sixteen chapters, and practically only three of them are devoted to asthma. It is not until the twelfth chapter is reached that there seems to be even the most remote reference to that subject. This, we think, is pretty clearly shown by the fact that the initial headings to this chapter are:—"Introduction—History—known to be described by Hippocrates." Even in an exhaustive treatise on the subject we should expect to get beyond the time of Hippocrates at so advanced a stage of the work. In this short chapter quotations are frequent, but the next article on "Etiology" is made up almost entirely of extracts, the late Dr. Hyde Salter, whose book was published as far back as 1868, being laid heavily under contribution. The chapter on "Treatment" is ambiguous, and although the author professes to "define his practice," we are left very much in doubt as to the methods

(a) "A Treatise on Unripe Cataract." By William A. McKeown, M.D., M.Ch., B.U.I., Surgeon to the Ulster Eye, Ear and Throat Hospital, Belfast; Lecturer on Ophthalmology and Otology, Queen's College, Belfast. Illustrated by 9 plates, containing 60 original drawings. London: H. K. Lewis.

(a) "Asthma: Recent Developments in its Treatment." By Ernest Kingscote, M.B., C.M., L.R.C.S. Edin., Fellow of the Medical Society of London. London: Henry J. Glaisner. 1899.

he adopts. A perusal of his "Illustrative Cases" throws very little light on the subject, although in a case of aortic disease (p. 130) the author states that he "read the Riot Act." Whether this document was read aloud to the patient, or perused by the author for his own edification in the privacy of his own chamber, we are not told, but we fail to understand how the reading of a legal document, or of any number of them, could cause the disappearance of a cardiac murmur. There is a mystery about the whole procedure which we are unable to fathom. The author gets very neatly over any difficulty that might be experienced in connection with the bibliography of the subject by referring the reader to the Index-Catalogue of the Surgeon-General of the U.S. Army. He evidently lays considerable stress on a series of "Don'ts" which he copies from a Trans-Atlantic paper. The following are examples:—"Don't conclude that every murmur means disease of the heart; don't neglect to note the character of the pulse when you examine it; don't examine the heart through heavy clothing." For whose benefit these sage maxims are reproduced we "don't" know. If books were classified on the same principle as stage plays this particular work would undoubtedly be placed in the category of farcical comedy.

LIFE OF MAN ON THE HIGH ALPS. (a)

PROFESSOR MOSCO has long been known as a past master of the subject of muscular work and of the influences brought to bear on it by various concomitant circumstances. He is also an expert Alpine climber. No one, therefore, could be better fitted for a study of the variations induced in the phenomena connected with muscular action or of the circulatory, respiratory and other changes produced by residence in high altitudes. The present volume is worthy of its author's reputation. Wishing to study some of the problems presented by life in the High Alps, Professor Mosco determined to take up his abode on the summit of Monte Rosa, 4,580 metres above the sea, in the hut named after the present Queen of Italy. Here he could conduct at his leisure a number of accurate researches into the various effects produced by high altitudes upon the bodily processes. The subjects of his experiments were provided in the persons of ten soldiers belonging to the Italian Alpine regiment. It would be impossible here to detail the facts observed by Professor Mosco during his stay on Monte Rosa, or even a tithe of the experiments recorded in this book. In the first place we may say that it is exquisitely illustrated, and that the translator has done his work with great ability.

The chief subjects investigated comprise the phenomena shown by muscular force, respiratory action, circulation of the blood, and condition of the heart, mountain sickness, diet, body temperature, training and cerebral conditions as produced at great heights.

Perhaps the most interesting part of the book for those who are not specialists in physiology, is that which deals with accidents caused by excessive fatigue and nervous exhaustion. Mosco has before now shown that every act of the will, even by the simple forcible clenching of the hand, causes some degree of cerebral fatigue; that this contraction of the muscles brings about a consumption of force in the brain, which requires renewal.

In mountain climbing he notes that the member of a party who occupies the foremost position, and so is at the fore end of the rope, suffers sooner from fatigue than the others. This is not only due to the greater amount of work entailed in cutting steps, &c., but arises also from the greater responsibility. On the other hand, however, the front man of an Alpine party having to cut steps and pick the way, is always stronger and more full of courage than those who have to wait upon him. Illustrative examples are also given of the profound mental effect which the severe labour and excitement caused by Alpine ascents produce. The numerous other

points of interest must be consulted in the original. The whole book is an example of the truism that truth is stranger than fiction.

Medical News.

ANOTHER case of death from anthrax was the subject of an inquest at the London Hospital on Saturday last, the victim being a man, æt. 54, a horse-hair curler. It was stated that another man was at present under treatment at St. Bartholomew's Hospital for the same disease.

Royal College of Physicians, Edinburgh; Royal College of Surgeons, Edinburgh; and Faculty of Physicians and Surgeons of Glasgow.

The quarterly Examinations of the above Board in Edinburgh, took place in October, with the following results:—

First Examination, 4 Years' Course. Of 11 candidates entered, the following 5 passed the examination:—

Randal Herley, William Anderson, Norman Pigott Fairfax, John Wilson, and Patrick James Kerwin: and 1 passed in Histology and 1 in Chemistry.

First Examination, 5 Years' Course. Of 35 candidates entered, the following 13 passed the examination:—

Lionel Walpole Thomson, Thomas McMaster Glen, Peter Oswald Jollie, John Joseph Lawton, John Archibald Turnbull, John Bryden, Cecil James Todd, David Haig, John Walker, Gerald William Smithwick, Michael John McCarthy, Robert Septimus Walker, and Edward Rainsford Mumford; and 3 passed in Physics, and 2 in Biology.

Second Examination, 4 years' course. Of 20 candidates entered the following 7 passed the examination:—

William Christopher Brown, Sidney Gerald Gomes, Claude St. Aubyn Farrer, William Henry Burnhill, Felix MacSwiney, Walter Percy Warburton, Morgan Howard Howard Jones, and 2 passed in anatomy, 1 in physiology, and 3 in materia medica.

Second Examination, 5 years' Course. Of 22 candidates entered the following 10 passed the examination:—

Ryder Percival Nash, Clara Hind, Joseph William Robert Sutton, Percy Jeremiah Bateman, John Browne Grogan Mulligan, Daniel Joseph Cagney, Robert Thompson, John Arthur Doyle, William Robert Addison Coates, and Thomas Fryer Okell.

Third Examination, 5 years' Course. Of 29 candidates entered the following 17 passed the examination:—

Charlotte Budd, John Blair Conner, Henry Ayrton Chaplin, George Herbert Leon Hammerton, David Crombie, William Brown Heagerty, Alexander Wilson, Frew, Henry Christian, Ernest Quin, Prudence Elizabeth Gaffkin, John Philip Cameron, Alice Miles, Charles Stephenson Oliver, Robert Peel Parker, John Bulman Mason, John Bell Walker, George Weldon Hibbert, and Basanta Kumar Chatterjee, and 1 passed in Pathology and 2 in Materia Medica.

Final Examination. Of 107 candidates entered the following 52 passed the examination and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. and S.G.:—

William Hewley Wharton, Sydney Edgar Price Philip Heywood Hadfield, John Archibald Wolverson, William John Morgan, John Allen Scotland, Martin Francis Ellis, Nellie Jardine, Elizabeth Beatty, Alice de Boer, Daniel William Jones, Eyre William Powell, Charles George Streeton, Leeds, Bartholomew, Francis Murphy, Alice Learmonth McKenzie, William Morris Williams, Allan Douglas Cameron, William Frederick Oliver, James Curtis Franklin, Douglas Massey Burnside, Nathaniel Hodgkiss, James Duncan Wilson, John James Scanlan, Jean Sinclair, Dobson Robertson, William Welsh, John McClintock, Arthur Gibson, Roderick McKenzie Skinner, Joseph Fulton, Prabala Rama Chandrayya, Arcot Kodanda Parri Mudali, James Clement Purcell Beardon, Charles Breginton Salway, John Smith Guthridge, Charles Richardson White, James Michael O'Sullivan, George Powell Hay (with honours), Henry Grattan Johnston, Ewen Mackenzie, Sidney Jacob, Robert James Love, John Kirkpatrick, John Ebenezer Waymark, Hugh John Drennan Mackay, Bartholomew Connolly, Lionel Robert Popham, James Valentine Roche, James Michael Aloysius Manning, John Joseph Fuller, Harry Parker Dall-y, Charles Louis Francis, and Robert Jackson Mackay; and 12 passed in the division of Medicine and Therapeutics, 2 in Surgery and Surgical Anatomy, 13 in Midwifery, and 10 in Medical Jurisprudence.

The following gentlemen, having passed the requisite Examinations, received the Conjoint Diploma in Public Health:—

Maurice Paterson, John William Myers, William McLean, Joseph Chambers, John Geddes McColl, and Alexandre di Fonseca Dias.

(a) "Life of Man on the High Alps." By Angelo Mosco. Translated from the Italian by E. Lough Kiesel. London: T. Fisher Unwin, 1899.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

REPRINTS.—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them, at half the usual cost, on application to the printers before the type is broken up.

THE WAR FUND.

THE SUM now being raised for the widows and children of soldiers killed in the Transvaal War is assuming magnificent proportions, contributions from Her Majesty the Queen to working men in various factories flowing in from all sides and from all parts of the United Kingdom. Theatrical managers and manufacturers alike are vying with each other in special efforts, the latest being that of "Vinolia," which promises to contribute one halfpenny for each cake of soap sold within a month; and so enormous is the consumption of this popular article, that the proprietors anticipate the War Fund will benefit by nearly 27,000 from this source alone.

TYPEWRITTEN letters may be reproduced to the extent of several hundreds from one original, all equal in appearance to an ordinary typed letter, and for this work the "Automatic Cyclostyle" has no rival, the best possible results being obtained on account of the evenness of rolling.

A PHILANTHROPIC ADVERTISEMENT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

"A little nonsense now and then,
Is relished by the best of men."

SIR,—The offer made under above heading in your "Notices to Correspondents" last week, reminds me of a similar offer made by an American, who advertised he would remove all of a person's teeth for two dollars and insert a complete new set for ten dollars, besides giving six months' credit. "People are fond of bargains, so there was a rush for the dentist's office. He was busy for two weeks pulling teeth, and at the end of the time numbers of people had empty gums, and a bone dust factory in the neighbourhood doubled its workmen to grind the teeth into bone dust. While people were waiting for the new sets the abandoned scoundrel eloped with the hotel keeper's wife, and now 2,000 or 3,000 people cannot eat anything tougher than gruel or soup. All the butchers have shut shops, and not a biscuit has been sold for months. One man, it is said, whittled out a wooden set for himself, but the first glass of whiskey he took set the teeth on fire. The dentist will hear of something to his advantage if he comes back."—From "Awful Crammers," by Josh Billings.

I am, Sir, yours truly,

A. D.

GENERAL PRACTITIONER.—The treatment of alopecia areata is varied, and fully laid down in the text books on dermatology. As opposed, however, to drug treatment, a French authority claims that much can be done by means of mechanical irritation. He recommends a stiff brush to be applied to the affected area, and to be used from four to six times a day so as to cause hyperæmia of the part.

PROFESSOR CHIENE ON MISTAKES IN DIAGNOSIS.

The most common cause of mistakes, remarked the speaker in a recent address, is the imperfect, careless examination of a patient. Ignorance is thought to be the most common cause of mistakes. My experience does not lend itself to that view. To imperfect examination, I think, is due the majority of my mistakes. Learn from your mistakes. Be methodical as well as thorough. When you touch in surgery, make your diagnosis, if possible, painlessly.

THE WEIR-MITCHELL TREATMENT.

A CORRESPONDENT writes:—Weir-Mitchell published his original plan in a work entitled "Fat in Blood, an Essay on the Treatment of Certain Forms of Neurasthenia and Hysteria." Playfair also describes the method in his work on "The Systematic Treatment of Nervous Prostration and Hysteria." The subject is also dealt with at some length in Allbutt's "System of Gynecology." The last edition of the first-named work is dated 1898.

Meetings of the Societies and Lectures.

WEDNESDAY, NOVEMBER 15TH.

ROYAL MICROSCOPICAL SOCIETY (20, Hanover Square, W.).—7.30 p.m. Mr. A. Earland: Exhibition of Foraminifera.

SOCIETY OF ARTS.—8 p.m. Sir J. W. Barry: Opening Address of the 146th Session.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—4.30 p.m. Dr. Eddowes: Keratoses. (Post-graduate Course.)

THURSDAY, NOVEMBER 16TH.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road).—8.30 p.m. Dr. A. H. N. Lewers: On some Interesting Cases of Fibroid Tumours of the Uterus.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—5 p.m. Dr. D. Grant: Diagnosis of Nasal Diseases characterised by Pain, Disturbances of Smell, &c.

FRIDAY, NOVEMBER 17TH.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND (Physiological Theatre of the London School of Medicine for Women, Hunter Street, W.C.).—4 p.m. General Meeting. Election of Officers for the ensuing year. Communications:—Mr. S. Boyd: A Persistent Left Inferior Vena Cava. Miss Stoney (introduced by Mr. S. Boyd): Specimen of Sacculated Esophagus.—Prof. A. M. Patterson: Child's Skull showing Parietal Perforations.—Prof. B. C. Windle and Mr. F. G. Parsons: Note on the Morphology of the Biceps Flexor Cruris.—Mr. C. B. Lockwood: Lantern Demonstration of Certain Points in the Lymphatic System of the Appendix. Meeting of Council to Elect Members of Committee of Management.

Vacancies.

Bracebridge Asylum, Lincoln.—Junior Assistant Medical Officer, unmarried. Salary £125 per annum, with furnished apartments, board, attendance, &c.

British Hospital, Buenos Aires.—House Surgeon. Salary £200 first year, £250 second, £300 third, with board, lodging, and wine allowance. Apply to Dr. Louis Colbourne, Berkhamsted, Herts. Carmarthenshire Infirmary.—Resident Medical Officer for 12 months, unmarried. Salary, £100 per annum, with furnished apartments, board, attendance, fire, gas, and washing.

Derby Borough Asylum.—Assistant Medical Officer. Salary £120 per annum, with board and washing.

Liverpool Dispensaries, 34, Moorfields, Liverpool.—Senior Surgeon of the East Dispensary, unmarried. Salary £200 per annum, with board and apartments.

Suffolk General Hospital.—House Surgeon. Salary, £100 a year, with board, lodging, and washing. Apply to the Secretary, Bury St. Edmunds.

Three Counties Asylum.—Second Assistant Medical Officer, unmarried. Salary commencing at £125 per annum, with board, apartments, washing, and attendance. Apply to the Clerk to the Visiting Committee, St. Neots, Hunts.

Appointments.

BAKER, JOHN, M.B., C.M.Aberd., Deputy Superintendent of the State Asylum at Broadmoor.

BENDLE, L. H., L.R.C.P., M.R.C.S., Medical Officer to the York County Hospital.

CLOME, NAPIER, L.R.C.S.Irel., L.R.C.P.Edin., Medical Officer for the Chard No. 2 Sanitary District.

McELLIOTT, MAURICE G., D.P.H., L.R.C.P., L.R.C.S.Irel., Medical Superintendent of Belper Isolation Hospital.

SCOTT, W. J., L.R.C.P., L.R.C.S.Irel., Medical Officer for the No. 1 Sanitary District of the Windsor Union.

SMITH, W. BROWNLOW, B.A., M.D., B.Ch., B.A.O. (T.C.D.), Deputy Medical Superintendent of the Belper Isolation Hospital.

SQUIRE, M.F., M.B., B.S.Durh., L.R.C.P.Lond., M.R.C.S., Medical Superintendent and Medical Officer of the Workhouse for the Parish of Paddington.

WILLIS, HARRY LEGGE, M.R.C.S., L.R.C.P.Lond., Junior Assistant Medical Officer to the Govan District Asylum.

Births.

NOBLE.—On November 7th, at The Moorings, Walthamstow, the wife of W. G. Noble, L.S.A., of a daughter.

WOHLMANN.—On October 25th, at Gay Street, Bath, the wife of Arthur Stanley Wohlmann, M.D., B.S., of a daughter.

Marriages.

HAMILTON—DEARMAN.—On November 8th, at St. Giles's Church, Bramhope, Rower Kerr Hamilton, M.B.C.S.E., L.R.C.P.I., of Woodbine Cottage, Whittle-le-Woods, Chorley, to Edith, eldest daughter of William Dearman, of Sydney, N.S.W.

Deaths.

ADAMS.—On November 10th, at 241, Mosley Road, Birmingham, Gerald W. Adams, M.B.C.S., L.R.C.P., aged 35, son of Dr. Ernest Adams, of Clifton, Derby.

BURY.—On November 8th, at Eastbourne, John Walter Bury, M.D., aged 63 years.

DIXON.—On November 7th, at Chepstow, Thomas Dixon, M.D., formerly of Cheshunt, and Norfolk Crescent, London, aged 74.

MORLEY.—On November 11th, at 45, High Street, Portsmouth, Frederic Morley, M.R.C.S., L.S.A., aged 57.

WIGAN.—On November 9th, at Portishead, Somerset, of pneumonia, Margaret, the beloved wife of George Wigan, M.D., aged 73.

THE TREATMENT OF ACUTE PSYCHOSES BY REST IN BED.

By DR. P. SÉRIEUX,

Physician to the Asylum for the Insane for the Department of the Seine.

[SPECIALLY TRANSLATED FOR THE MEDICAL PRESS AND CIRCULAR.]

(Continued from page 502.)

THE data which we have given are far from complete, and are useful in so far as they define the general indications for applying the treatment. They justify, however, the use of this treatment in certain cases from a physiological point of view; in cases of excitement for example, it has the advantage of moderating cardiac and respiratory movements, which are always somewhat tumultuous, and of lowering the temperature which is sometimes above normal. In conditions of depression rest in bed regulates the functions of nutrition, overcomes irregularities of the circulation, and prevents the patient from taking cold, while it also checks disassimilation.

From a clinical point of view, most authorities are agreed on the indications for the bed treatment. They can be very briefly formulated:—The treatment is indicated whenever rest of the brain or of the entire organism is necessary. Moreover, with persons suffering from the acute psychoses, the special symptom to be looked for is the exhausted state of the brain and of the organism in general. Cerebral exhaustion brought on by irritation of the moto-sensory and sensory centres in the cortex, exhaustion following agitation, insomnia, and inanition plainly call for rest, physical as well as mental.

It is unnecessary to emphasise the indications for physical rest, the importance whereof was insisted upon by the earlier observers. Weir-Mitchell looks upon his method as particularly suitable in cases of prostration, anæmia, and emaciation. According to Ludwig Meyer, who has for thirty-five years practised this treatment, it is especially to the physical manifestations that we must look for indications of the necessity for this treatment, and the length of time it will require to be applied. This author admits that mental symptoms are markedly benefited thereby. In short, physical conditions requiring rest in bed are loss of appetite, emaciation, general debility, advanced age, the puerperal state, chlorosis, anæmia, circulatory disturbances, and febrile or subfebrile conditions. These various symptoms frequently present themselves in melancholics and in maniacal patients, as well as in post-infectious, toxic, and puerperal psychoses. With regard to indications for psychical and cerebral rest, they are always present in acute cases.

It does not matter whether they are states of excitement, depression or confusion, or even of acute

delirium with hallucinations—all these psychoses originate from more or less serious impairment of nutrition of the cerebral cortex, and sometimes even of the whole cerebro-spinal axis (polyneuritic psychoses). If the brain be overwrought by undue activity of the motor zones (maniacal conditions), of the sensory zones (melancholia), of the sensorium (hallucinations), or if its activity be paralysed for the time being by a toxic influence (confusion), in all these cases it is a matter of primary importance to give the intoxicated or overwrought organism rest, so as to permit the processes of nutrition to return to normal. Rest in bed alone can secure complete repose of the brain. Apart from the fact that the horizontal decubitus facilitates the cerebral circulation, and the brain is therefore better supplied with blood, the treatment further renders complete relaxation of the muscles possible, with, consequently, rest of the motor centres. It also reduces to a minimum peripheral stimulation (thermal, visual, auditory, cutaneous, &c.), and therefore all motor reflexes. It is favourable to sleep, and it diminishes the intensity of hallucinations by reducing the sources of excitement.

Rest in bed, moreover, advantageously modifies the environment. In a ward where all the patients are in bed order and silence are seldom disturbed because of the absence of every kind of excitement and disorder associated with promiscuity. Conversation with, or the mere sight of, other patients, their goings and comings, the meals in common, intensify the sufferings of melancholic people, just as they excite maniacal patients, and reinforce the sensory disturbances of patients suffering from hallucinations. All these troublesome influences are avoided in our wards, where patients are ensured physical as well as mental repose.

In short, rest in bed is advised in all the acute psychoses, on account of the necessity for complete rest of body and mind. This gives one some idea of the number of sufferers amenable to the treatment, the proportion varying from a third to over a half of the total inmates.

In a good many foreign asylums an excellent method has been adopted in virtue of which every patient on admission, after having taken a bath and put on clean clothes, is kept in bed for several days. This method is justified by the fact that there are very few patients who, on admission, are not emaciated and prostrated by restlessness, insomnia, and inanition, or whose general state of health does not leave much to be desired.

We agree with Paetz, who asserts that patients who at first appear to be free from nutritional disturbance nevertheless display symptoms of excitement, and exhaustion, circulatory, digestive, and nutritive disturbance. The majority, we find, are quite incapable of calling one's attention to these various symptoms, and this shows the necessity of a general method of investigation applied in a systematic manner.

Under treatment by rest in bed a fairly rapid im-

provement both in the physical and mental condition of the patient is brought about. Excitement and irritability are calmed, fits of depression are rendered less frequent, and hallucinations become less vivid, digestion is less hampered, and the general condition improved. Lastly, the patients have every opportunity of obtaining refreshing sleep on the occurrence of an interval of comparative quiescence.

In short, the amelioration of the symptoms of acute psychoses following rest in bed is unquestionable. We may be asked whether the same can be said of influence of rest in bed on the subsequent course of the disease; in other words, does the treatment bring about recovery sooner or better than other methods of treatment? It is impossible to answer such a question categorically, but one fact appears to us incontestable, viz., here we have a method of treatment which invariably attenuates the intensity of the more acute symptoms of mental disease, which gives the exhausted brain, and the organism as a whole the best chance of remedying grave disturbances of nutrition. Such a method must rationally conduce to recovery. It certainly averts the disastrous physical and psychical complications to which the fatal termination in acute cases is invariably due, and it helps to avert dementia and passage into a chronic condition. It may not be amiss to give the opinions of various authors on the benefits of rest in bed. Professor Ludwig Meyer, with his wide experience, states that, with few exceptions he had to congratulate himself on the results of the treatment. One of the most marked features of this treatment, he observes, is the rapidity with which the first signs of improvement make their appearance. Timofeier and Govseier agree that attacks of delirium treated by rest in bed display less intensity and pass off sooner. According to Bernstein, patients treated in this way do not recover more quickly, but their symptoms are markedly attenuated, and Rohrick states that without shortening the period of the attack the treatment obviates denutrition (collapsus), and reduces the symptoms of agitation. There are other advantages, in addition to those already mentioned, to be placed to the credit of this treatment. The use of hypnotics and sedatives can more easily be dispensed with, and isolation of patients in special wards, which has been so much abused, is rarely called for. The nursing of the patient is facilitated, the patient does not contract uncleanly habits (gâtism, coprophagy) as many isolated patients are apt to do. Organic affections no longer run the risk of being overlooked and consequently not treated, though these might easily escape recognition were it not for the facility of examination ensured by the patients being undressed and in bed. Visceral complications which might be caused by sudden changes of temperature or prolonged exposure to cold in melancholic patients, for example, who dislike movement of any kind are avoided by the equable temperature which is maintained. In addition to this the treatment by rest in bed leads the patient to be treated not as a pariah, but as an ordinary patient as well by his nurses as by the members of his own family. This treatment, moreover, in certain cases may impress the imagination of the patient, and assist in convincing him of the morbid character of his symptoms, and so accustom him to the idea that he requires care. Lastly, this treatment has one result which, in our minds, is all important, viz., the complete transformation which it brings about in the environment of our lunatic asylums. The mere fact that half the patients are in bed, and the suppression of isolation in padded rooms, the "prison," where it has long been the custom to huddle together the curable and the incurable cases, go far to convert the lunatic asylum into an ordinary hospital for the treatment of mental disease. Disciplinary measures are replaced by appropriate thera-

peutical treatment, and the attendants become nurses. We have done with the aggregations of restless and agitated patients, who mutually excite each other, rendering any serious examination of the symptoms impossible. Instead of these "lunatic dens" we have wards where those suffering from acute diseases, requiring as much care as patients suffering from typhoid, are treated in bed, are carefully looked after and daily examined.

(To be continued.)

REMOVAL OF MYOMA UTERI BY ABDOMINAL HYSTERECTOMY (a).

By CHARLES RYALL, F.R.C.S.,

Surgeon to the Cancer Hospital, Brompton, and to the Gordon Hospital for Diseases of the Rectum; Surgeon to Out-Patients, London Lock Hospital.

S. E., æt. 48, an unmarried woman, was admitted into the Cancer Hospital on July 18th, 1899, and gave the following history:—For the last *ten years* she has suffered from *pain* in the abdomen, over the sacrum, and down the thighs, and this has been getting worse of late. Palliative treatment had been tried for some considerable time, but without alleviating her symptoms to any great extent, and she was therefore anxious to have any operation performed that would give her the necessary relief.

She was a well-nourished woman, and never had any previous severe illness.

The catamenia were regular, duration about five days, amount lost not great, and always accompanied with pain.

On examination, a hard and irregular shaped tumour could be felt rising out of the pelvis and reaching upwards to a point about midway between the umbilicus and the pubis. Per vaginam a hard rounded swelling was found in Douglas's pouch, and appeared to be part of the tumour that was felt in the abdomen. The whole mass was incorporated with the uterus and almost completely fixed in the pelvis.

Abdominal hysterectomy was recommended as the only means of curing the pain, and moreover there was every evidence that the tumour was increasing in size, and frequency of micturition, combined with troublesome constipation, showed that the functions of the bladder and rectum, were being interfered with.

Operation, July 28th, 1899.—The abdomen was opened by the ordinary median incision, extensive adhesions of the omentum, small intestine, and sigmoid had to be freed before the tumour could be brought into view. After ligating and severing the upper parts of the broad ligaments, turning down a flap from the anterior surface of the uterus, and partly enucleating the tumour in the pouch of Douglas, one was enabled to lift the whole mass out of the pelvis. There was no difficulty then in securing the uterine vessels and cutting through the cervix. The only other things of note in the operation were the enucleation of a small myoma from the cervical stump, and the method adopted in dissecting the posterior flap. Instead of dissecting it from above downwards, a procedure which is not always easily accomplished, it was dissected from below upwards after the cervix had been divided. The operation was finished off in the ordinary way, which has been described so many times, and the patient did not appear to suffer from any great amount of shock.

I saw her daily for a week after operation, and during that time she made rapid progress in recovery,

(a) Read before the British Gynecological Society, November 9th, 1899.

and on the last day of the week she was taking solid food and appeared to be perfectly well. I saw her again on the twenty-fifth day after operation, and then learned that she had gone on very well up to the twenty-first day and had not given the least cause for anxiety. On the twenty-first day she was seized with sudden and acute pain in the calf of the right leg, and on examination no pulsation could be felt in the posterior tibial artery though it persisted in the dorsalis pedis artery. The following day the pulsation disappeared from the dorsalis pedis and dry gangrene set in. On the third day after the onset of these symptoms she developed aphasia which rapidly became complete. When I saw her on the twenty-fifth day after operation she was unconscious and had lost control of both sphincters. There was marked rigidity of the muscles of the right side of the body, both pupils were equal and dilated, and the left proved to be less active to light than the right. The right leg was undergoing dry gangrene to within two inches of the knee-joint. The patient became gradually worse, and died on the twenty-eighth day after operation.

No post-mortem examination was made owing to the objection of her relations.

Clinically, one was unable to detect any signs of arterial or cardiac disease, and I am at a loss to explain why she should have developed this trouble. An embolus apparently first lodged in the posterior tibial artery, and then thrombosis extended backwards to the bifurcation of the popliteal and thus implicated the anterior tibial. The cerebral trouble was quite independent of this.

NOTES ON AN UNSUCCESSFUL CASE OF ABDOMINAL HYSTERECTOMY

FOR

MYOMA. (a)

By HERBERT SNOW, M.D. (Lond.), &c.,

Surgeon to the Cancer Hospital since 1876.

CONSIDERING that more may often be learnt from a failure than from even a brilliantly successful case, I venture to bring the following under the notice of the Society. Although incomplete, the facts seem to me of sufficient importance to be narrated very briefly; and of considerable significance in relation to a prevailing fashion in technique.

Sarah L., single, æt. 38, was admitted into the Cancer Hospital on August 14th last, with multiple myomata uteri, noticed five to six years. There had been recently a rapid increase, with a feeling of distension and weight in the lower part of the abdomen. Latterly there had been amenorrhœa for periods of two to three months. The mass filled Douglas' pouch. In front, the large "lump" was prominent slightly to the right of the umbilicus. A consultation was duly held, and the patient pronounced suitable for abdominal hysterectomy.

The patient was a rather florid young Jewess, highly neurotic, and with obvious indications of free resort to alcohol. She had no albuminuria, or other sign of organic disease. There was plainly "alcohol in the family;" as before the operation, a brother came to see the patient in the hospital ward, in an advanced stage of intoxication, and had to be turned out.

Abdominal hysterectomy was performed on August 25th. The method adopted was that modification of Dr. Heywood Smith's, which I have previously described before the Society, which involves dissecting off thin muscular flaps, and not merely the

peritoneal coating of the uterine tumours. The Trendelenburg posture was necessary. The abdominal wall was sutured on the line I have invariably used for celiotomies during the past two years, and which has always answered perfectly, viz., a catgut continuous suture for the peritoneum, and interrupted silk or silkworm gut for the remainder of the abdominal wall. The only untoward point in the operation was that the dissection of the projecting bosses took over two hours, and so involved prolonged etherisation, always more or less hazardous in an alcoholic patient. [Specimen and temperature-chart exhibited.]

The next day all was well. There was no vomiting, a good pulse, and a very favourable temperature-reaction. The next morning my favourite enema of glycerine and peppermint water was administered early, and the bowels acted well. All through the night, however, the patient was very restless and excitable. The season, it will be remembered, was then excessively hot. On paying an early visit at ten o'clock, I was informed she had tried to get out of bed, had called out that they were giving her ether instead of soda-water, had been pushing away the nurses with all her strength, and had, in short, been so violent that the friends had been sent for merely to restrain her. The tongue was moist and clear; and the attack was hysterical rather than maniacal, the patient subsequently expressing to the nurses her contrition for having been so troublesome. When I saw her she was exhausted by these struggles, and the pulse was rather slow; but she was calm, answered rationally, and showed no bad symptom. At twelve, however, she began to collapse. The house surgeons transfused, but without even transient improvement. She died at half-past two. Being a Jewess no autopsy could be obtained.

In explaining the mode of death, I am loth to fall back upon the vague term "shock." There may have been internal hæmorrhage; but I consider that possibility negatived by the absence of any improvement after the transfusion. I would ask the Society to remember the highly interesting case reported last session by my colleague, Mr. Charles Ryall; and to bracket mine therewith. In that instance, vomiting persisted after celiotomy, and death took place in about six days. Then it was found that the peritoneum had failed to unite; that the internal catgut layer of sutures had ruptured, and that the intestines lay in direct contact with the muscular parietes.

Although unable to verify the view, I therefore infer that death was due in this unfortunate case also to rupture of the flimsy catgut layer holding the peritoneal edges. I submit to the Society that the present fashion of suturing in layers is highly dangerous, without provision to secure the whole thickness of the parietes. *We are completely at the mercy of our patient.* So long as she lies still, all goes well; but otherwise, the slightest tendency to hysteria or to mania proves unavoidably fatal. The old mode of a single layer of silkworm gut sutures traversing every coat was really far safer than that recent plan of numerous layers, amounting in Howard Kelly's hands actually to four.

Provided primary union is secured, there is little chance of the common bugbear, parietal hernia. But, certainly, so far as I have seen, we can much more confidently rely upon obtaining that union by an independent layer of peritoneal suture than by the former plan. Hence I suggest, as the ideal method, three or four silkworm gut sutures traversing the whole parietes, in addition to the two layers of catgut for peritoneum, and silk for muscle and skin. This would render impossible the accident I presume with confidence to have here taken place.

(a) Read before the British Gynecological Society, November 9th, 1899.

THE STRAWBERRY : ITS PLACE IN THE HISTORY OF THERAPEUTICS.

By JOHN KNOTT, M.A., M.D.,

CH.B. AND DIP. STAT. MED. (Univ. Dub.) ;
M.R.C.P.I. ; M.R.I.A., ETC.

THE recent recommendation of the use of the strawberry as a special dietetic treatment of the innumerable ills of gout, may make the therapeutic history of this very palatable fruit interesting to the majority of the reading members of the profession. I have accordingly culled the most important evidence on the subject from the pages of the prominent herbal authorities of the past centuries, and submit them for the perusal of the readers of the MEDICAL PRESS AND CIRCULAR.

The quaint and always entertaining John Gerard gives his readers the following information on the subject of the therapeutics of the strawberry :—

"*The Kindes.*—There be divers sorts of Strawberries, one red, another white, a third sort greene, and likewise a wilde Straw-berrie, which is altogether barren of fruit.

"*The Description.*—The Straw-berrie hath leaves spread vpon the ground, somewhat snipt about the edges, three set together vpon one slender foot-stalke like the Trefoile, greene on the vpper side, and on the nether side more white : among which rise vp slender stems, whereon do grow small floures, consisting of five little white leaves, the middle part somewhat yellow, after which commeth the fruit, not unlike to the Mulberrie, or rather the Raspis, red of colour, hauing the taste of wine, the inner pulpe or substance whereof is moist and white, in which is contained little seeds : the root is threddy, of long continuance, sending forth many strings, which diagnose themselves far abroad, whereby it greatly increaseth.

"*The Temperature.*—The leaves and roots do coole and dry, with an astriction or binding quality : but the berries be cold and moist,

"*The Vertues.*—A. The leaues boyled and applied in manner of a pultis taketh away the burning heate in wounds : the decoction thereof strengthneth the gummies, fastneth the teeth, and is good to be held in the mouth, both against the inflammation or burning heate thereof, and also of the almonds of the throat : they stay the ouermuch flowing of the bloody flux, and other issues of blood.

B. The berries quench thirst, and do allay the inflammation or heats of the stomack : the nourishment which they yeeld is little, thin and waterish, and if they happen to putrifie in the stomacke, their nourishment is naught.

C. The distilled water drunke with white Wine is good against the passion of the heart, reuiuing the spirite, and making the heart merry.

D. The distilled water is reported to scour the face, to take away spots, and to make the face faire and smooth ; and is likewise drunke with good successe against the stone in the kidnies.

E. The leaues are good to be put into Lotions or washing waters, for the mouth and the priuie parts.

The ripe Straw-berries quench thirst, coole heate of the stomack, and inflammation of the liuer ; take away (if they be often vsed) the rednesse and heate of the face.

In the voluminous "*Theatrum Botanicum*," Parkinson gives the following description and history :—

THE NAMES.

The whole plant is called in Latine *Fragaria*, and the berries *Fraga* a fructus fragrantia odoris & gustus, for it hath no certaine Greek name that I know, unless as *Tragus* thinketh it may be referred

to the *τριφυλλον* of Dioscorides, or as others thinke to the *κόμερον* Comaron of Apuleius, but neither of them is likely ; others suppose that Dioscorides did understand this plant under his *ανταφάλλα*. Some have called it *Rubus Idæus non spinosus*, but there is a shrubbe like unto the Raspis that beareth no thornes, as I have showed. Pliny maketh mention of *Fraga*, lib. 25, c. 9. *Servius* calleth them *Mora terrestria*, and therefore some would referre it to the *Chamæbatus* : the Italians call the plant *Fragheria*, and the berries *Fraghe* and *Fragole* ; the French *Fraisier* and *Fraises* ; the Germans call the fruit *Erdbeer* ; and the Dutch, *Erdbesien* ; and we in English, *Strawberries*.

THE VERTUES.

These Strawberries . . . the leaves of them all being cooling in the first degree, and yet some say hot and drying in the second, the roots is more drying and binding, the berries while they are greene are cold and drie, but when they are ripe they are cold and moist : the berries are excellent good to coole the liver, the blood and spleene, or an hot chollerick stomacke to refresh and comfort the fainting spirits, and to quench thirst ; they are good also for other inflammations, yet it behoveth one to be cautious, or rather to refraine them in a feuer leas by their putrifying in the stomacke, they encrease the fits and cause them to be the more fierce : the leaves and rootes boiled in wine and water and drunke doe likewise coole the liver and blood, and asswage all inflammation in the raines and bladder, provoketh urine, and allaieth the heate and sharpnesse thereof : the same also being drunke staieth the bloody fixe and womens courses, and helpeth the swellings of the spleene ; the water of the berries carefully distilled, is a soveraigne remedy and cordiall in the palpitations of the heart, that is, the panting and beating of the heart, and is good for the overflowing of the gall, the yellow jaundise ; the juyce dropped into foule ulcers, or they washed therewith or with the decoction of the herbe and rootes, doth wonderfully clesne them and helpe to cure them. All lotions and gargles that are made for sore mouthes or ulcers therein, or in the priuie parts, or else where are made with the leaves and rootes hereof, which is good also to fasten loose teeth, and to heale spongie foule gummies : the same also helpeth to stay catarrhes or defluxions of rheume into the mouth, throate, teeth, or eyes : the juyce or water is singular good for hot and red inflamed eyes, if some thereof be dropped into them, or they bathed therewith. the said juyce or water is also of excellent propertie for all pushes, wheales, and other eruptions of hot and sharpe humours into the face or hands, or other parts of the body to bath them therewith, and helpeth to take away any rednesse in the face, and spots or other deformities of the skinne, and to make the skin cleare and smooth ; some use thereof to make a water for hot inflammations in the eyes, and to take away any filme or skin that beginneth to grow over them, or other defects in them that any outward medicine can helpe in this manner : Take what quantity of Strawberries you please, and put them into a brasse vessell, with a little salt cast upon them, which being covered, set into a wine cellar for eight dayes, in which time the berries will be dissolved into a greene water, which, being cleared from the rest, keepe in a glasse close stopped to use when you neede ; a droppe or two put into the eyes serveth for the purpose aforesaid ; some in misliking both salt and brasse for the eyes, make a water both for the eyes and for the deformities in the skinne, be it morpew, leprey, or the like in this manner : Into a large destillatory or body of glasse, they put so many Strawberries as they thinke meete for their use ; if a few, the lesser glasse body will serve, which, being well closed, let it be set in a

bed of hot horse dung for twelve or fourteene dayes, and after distilled carefully and the water kept for your use.

But good old William Salmon gives, as usual, the most comprehensive account of all (*Herbal*, London, 1711).

OF STRAWBERRY.

I. *The Names*.—It has no Greek Name that we know of; but it is called in Latine, *Fragaria*: and in English, *Strawberry*. The Fruit is called *Fraga*; (à fructus fragrantia odoris & gustus:) *Strawberries*. Pliny, lit. 25, cap. 9, makes mention of *Fraga*; and Servius calls them *Mora terrestria*: Yet it is no species of the *Morus*, whether you understand by it the *Mulberry* or *Bramble*.

II. *The Kinds*.—Authors make many Kinds hereof, but those which are most common with us, are 1. *Fragaria Sylvestris vel Nemorensis*, *Wood-Strawberry*. 2. *Fragaria vel Hortensis*, *Garden Strawberry*. 3. *Fragaria vel Fraga Magna Alba*, *Fraga Maxima Bohemica*, the great white *Strawberry*. 4. *Fragaria Viridis*, the *Green Strawberry*. 5. *Fragaria Minime Vesca, sive Sterilis*, the *Wild, or Barren Strawberry*.

III. *The First, or Wood Strawberry*.—The Description of this Plant is the General Description of all the Kinds, the material or chief difference being in the Form of the Fruit: Its Root then is reddish and long, with several small Fibres or Threads at it: which sends forth from the head thereof long reddish Strings, running upon the Ground, which shoot forth Leaves in many places, by which it is much increased. Its leaves are closed together at first springing forth, which afterwards spread themselves into three divided Parts or Leaves, every one standing upon a small long Footstalk, green on the upper side, grayish underneath, and snipped or dented about the edges: From among which, rise up small Stalks, bearing four or five Flowers at the tops, consisting of five white round pointed Leaves; something yellowish in the bottom, with some yellow threads therein: After which come the Fruit, made of several small Grains set together, in a Fleishy Substance (not much unlike in substance to a *Mulberry*, *Raspberry* or *Brambleberry*;) which are very red when they are ripe, and of a pleasant Winy taste, (as are all the kinds) in which are enclosed many small blackish Seed. The Berries of the *Wood Kind* are very red, and the smallest of all the sorts.

IV. *The Second, or Garden Strawberry* (which is our most Common kind. This according to the Opinion of Parkinson, is only the *Wood-Plant* Transplanted into our Gardens, where by the richness of the Soil it is advanced in Goodness, being full as red, if not redder; almost as large again, and also meliorated in its Winy Taste.

V. *The third, or great white Strawberry*. This is a very large Strawberry, extremely Fleishy, and of an admirable Taste, and for Beauty surpasses all others: Parkinson says that he had seen some of the Berries measured, which had been near five inches about: I have seen them of an extraordinary bigness, admirable to behold. I am apt to believe, that this is the so much admired *Virginia* kind, which I have seen grow to an admirable perfection in the Gardens in *Carolina*, exceeding any that ever I saw in *England*. It has been no long Inhabitant with us, being first brought hither from *Bohemia*. At first for want of Skill in managing it, it very rarely bore any fruit; but now, if Planted in good Ground, it bears in a vast plenty. Formerly a Gardiner (one Vincent Sion), living by the Bank-Side, near the old *Paris Garden* Stairs, said that from seven Roots, in one year and a half, from their increase, he had Planted an acre and a half of Ground, besides those which he gave away to his Friends, which bore strawberries of that Magni-

tude or Greatness never before mentioned. If you would have them bear kindly, you must not suffer them to grow with many Strings, but still cut them away. The Fruit of this differs, not from the *Garden red*, but in its Magnitude, this being so very much bigger, and not so globular, but of a more Oval form; and in its Color, it being much whiter, viz., of a yellowish white on one side, and enclining to redness on the other, when it is full ripe.

VI. *The fourth or Green Strawberry*. It differs not from the second kind or *Garden Strawberry*, but in its Fruit only, which is green on all sides when it is ripe, except on the Sunny side, where it is a little red or reddish; and in magnitude is much equal to the second or *Garden* kind.

VII. *The fifth, or Wild, or Barren strawberry*. Its Root is like the former, and in its Leaf much like to the first *Wood* kind, but differs in its flower (if it has any) which is Green, bearing rather a small head of green Leaves, many set thick together like unto a double Ruff, in the midst of which stands the Fruit, which, when ripe, shews itself to be soft, and something reddish, like unto a Strawberry, but with many small harmless prickles on them, which may be eaten and chewed in the Mouth, without any manner of hurt, and is pleasant like a Strawberry; but it is truly without any great Sap or Juice, and a little Styptick or harsh upon the Taste. It is no great Bearer, but those it does bear, are set at the top of the Stalks close together, pleasant to behold, and which a Gentlewoman may wear in her Bosom as a rarity instead of a Flower.

VIII. Gerard says, Its Roots and Leaves are like the others, but somewhat less, its Leaves softer, slightly indented about the edges, and of a light green color: Among which rise up slender Stems, bearing such Flowers as the Common Strawberry does, but lesser; which whither away, leaving behind a barren or chaffy head, in shape like a Strawberry, but of no worth or value.

IX. *The Places*.—The first grows in Woods both in *England* and *America*; upon Hills, Vallies, Woody and Shadowy places: But the four first kinds are inhabitants in our Gardens, all which I have seen grow admirably in *Carolina*, exceeding in Beauty, Largeness, and Pleasantness, any I ever saw grow in *England*. The *Barren* kind is a Wild sort, and has been found growing (as Gerard says), on *Black-heath*, *Greenwich Park*, &c., but for its rarity has been brought into Gardens.

X. *The Times*.—The Leaves are said to continue Green all the year: In the Spring they spread further with their Strings, and Flower in May, the Berries being ripe in June and July. The *Barren* one Flowers in April and May, but never bears any Edible Fruit.

XI. *The Qualities*.—The Roots, Leaves and Berries whilst green, are cold and dry in the first Degree, but the Roots more than the Leaves. Abstersive, Astringent, Arthritick, and Vulnerary. The ripe Berries are temperate in respect to heat or cold, and moist in the first Degree: Cool the Blood, Liver and Spleen, Comfortative and Cordial.

XII. *The Specification*.—The Leaves and unripe Berries stop Fluxes and Catarrhs, cool the heat of Fevers, heal Ulcers in the Mouth, Throat, and Tonsils; and stop the Courses in Women.

XIII. *The Preparations*.—Of the Roots, Leaves, and Green Berries are made. 1. A Liquid Juice. 2. A Decoction in Wine or Water. 3. A Lotion or Gargarism. 4. A Distilled Water. 5. An Ophthalmick. 6. The Ripe Berries. 7. A Syrup of the Same. 8. A Distilled Water from the same.

THE VIRTUES.

XIV. *The Liquid Juice*.—Taken to the quantity

of three or four spoonfuls or more, either mixed with the Syrup of the ripe Berries, or with a little Mutton Broth, Morning and Night, it cools the Blood and Liver, allays Inflammations of the Reins and Bladder, provokes Urine, takes away the heat, sharpness, and scalding thereof; stops Women's Courses and the Bloody Flux, and decreases the Tumour or Swelling of the Spleen. Applied to the Gums it fastens loose Teeth, stops Catarrhs, or Defluxions of Rheum to the Mouth, Throat, Teeth, and other Parts, and is singular good for hot, red, and inflamed Eyes, being dropt into them: As also to repel hot, red, and sharp Tumours or Eruptions in the Skin, whether Face, Hands, or other parts; and to take away redness of the Face, Spots or other Deformities of the Skin.

XV. *The Decoction of Roots, Leaves, or unripe Fruit in Water and Wine.*—It has all the former Virtues, being used in the same manner, and may be taken to half a Pint at a time Morning and Night.

XVI. *The Lotion or Gargarism.*—Take of the Liquid Juice or Decoction a Pint, Honey three or four Ounces, Spirit of Wine two Ounces, mix and dissolve. It cleanses and heals foul Ulcers in the Mouth, Throat, Privities, or other parts, heals Ulcerated and Spungy Gums, and fastens loose Teeth.

XVII. *The Distilled Water of the same Roots, Leaves and Berries.*—It is good for hot and inflamed Eyes, redness of the Face and Skin, and other Deformities of the same; hot Eruptions of the Same, Anthonies Fire, &c.

XVIII. *The Ophthalmick.*—Take of the former Distilled Water a Pint, Honey three Ounces, Spirit of Wine two Ounces, mix and dissolve. Dropt into the Eyes 3 or 4 times a day it is good against an Ophthalmia, redness, inflammation, and hot Rheums in the Eyes.

XIX. *The Ripe Berries.*—They cool a hot and choleric Stomach; as also the Blood, Liver, and Spleen: quench Thirst, and refresh weak and fainting Spirits.

XX. *The Syrup of the same Berries.*—It has all the same Virtues, and may be given two or three Ounces at a time upon Occasion.

XXI. *The Distilled Water of the Ripe Berries.*—It is a Cosmetick for the Skin, good against Fever, and Inflammations of the Eyes; Anthonies Fire, and other like hot Eruptions; Melancholy, Faintings and Passions of the Heart.

All readers of the above record must admit that the latest of the "new" remedies for gout has in former ages occupied a rather prominent position in the therapeutic armamentarium. And that the judicious internal administration of strawberries—with or without cream or other correspondingly pleasant adjuvant—will always prove "comfortive and cordial" as well as "arthritic," to the gouty as to those not so afflicted, the present compiler, for one, entertains no doubt whatever.

Clinical Records.

ST. GEORGE'S HOSPITAL.

Persistent Lockjaw in an Edentulous Subject, Relieved by Incising a Tender Portion of the Gum. (a)

By WILLIAM EWART, M.D., Cantab.

THE patient, a decorator, æt. 47, moderately addicted to alcohol, was suffering from an extensive chronic ulcer of the right leg. His illness began with a severe cold, three weeks before his admission into St George's Hos-

pital, on September 20th, 1899 (Med. Reg. No. 1605). The lockjaw set in suddenly in the night, a week later, when he woke in a fit of suffocation, due to the closure of his lips, unsupported by teeth, whilst the nasopharynx was probably closed by a spasm of the muscles of the palate. The same nocturnal attacks continued to occur in the Hospital until the trismus was relieved. The rigidity of the jaws, of the floor of the mouth, of the platysma of the neck, and of the abdominal muscles was intensified by excitement, but there was neither opisthotonos, nor any spasm of the limbs. Speech, respiration, and alimentation were much impeded, leading to loss of flesh and weakness.

The case was diagnosed from the first as one of reflex spasm from periosteal irritation and tenderness at the left posterior extremity of the upper jaw, and local treatment was recommended. This was finally resorted to, after various remedies had proved ineffectual, and the symptoms rapidly disappeared after the tender gum had been freely incised.

The case is a good illustration of the reflex tetanoid symptoms occasionally induced by irritation of the dental nerves. These cases do not present the complete symptoms of traumatic tetanus, they do not end fatally, and they are invariably cured by a removal of the offending cause. The few cases of fatal tetanus which have been observed after operations on the teeth were probably cases of accidental infection with the bacillus.

The case exhibited is a perfect instance of a purely reflex causation due to nerve irritation, since, owing to the absolutely edentulous and clean condition of the gums the mouth contained no source of septic infection.

A Case of Pigmentation of the Skin and of Partial Pigmentation of the Nails, simulating Addison's Disease, in an Asphalt Worker, and of Anæmia associated with Hepatic and Splenic Enlargement.

The patient, æt. 43, an Italian born in England, has been out of health since May, when he was laid up in bed for seven weeks with a severe attack of influenza, followed by great loss of weight and of strength. On admission he presented marked brownish discolouration of the skin, without any staining of the buccal mucous membrane, slight pyrexia, some dulness, and a few râles at the right apex, and considerable depression. The liver was moderately enlarged, and the spleen much increased in size. One of the left cervical glands was much enlarged, but is now much smaller. The diagnosis of Addison's disease was made on the strength of the pigmentation, of the feebleness of the pulse, the muscular weakness and of the clinical history of progressive emaciation since the influenza, and the brownish discolouration of the distal portions of the nails was regarded as an unusual feature of the affection. On further inquiry, however, it was ascertained that the discolouring of the skin had existed for upwards of twenty years, and that the patient had been constantly exposed to the smoke of heated asphalt. These circumstances, and the total absence of pigment from the proximal ends of the nails, both in the hands and in the feet, led to the abandonment of the original diagnosis, although the patient had greatly improved under treatment by suprarenal extract. The association of a glandular swelling with a marked splenic enlargement had suggested the unlikely view that the case might be one of Hodgkin's disease. The patient had had an attack of jaundice at the age of fifteen years, but no recent symptoms of hepatic disease. The blood presented decided decrease in the number of red cells with moderate leucocytosis, and the eosinophilic cells were increased in number.

CANCER HOSPITAL.

Case of Myomatous Uterus Removed by Subperitoneal Hysterectomy (a).

Under the Care of Dr. F. A. PURCELL,
Surgeon to the Hospital.

C. P., of Clapham, æt. 36, married, a housewife, admitted to the Cancer Hospital, September 13th.

(a) Shown at the meeting of the Medical Society of London, Nov. 13th, 1899.

(a) Read before the British Gynecological Society, November 9th, 1899.

1899, one child 18 years old, one miscarriage six weeks after. Menstruates regularly, amount normal. Looks a fairly healthy woman, but anæmic, tongue clean, bowels regular, defæcation not painful. A year or so ago she noticed herself getting stout, and suffers pain in abdomen at varying intervals. Has a yellow vaginal discharge, which, on examination proved to be non-specific. This was treated for four weeks, operation in consequence was postponed. Urine, sp. gr. 1020 acid, with a trace of albumen.

Abdomen distended by tumour in hypogastric region, it encroaches into right and left inguinal regions, it is dull, firm on palpation, movable, abdominal wall moves freely over its smooth surface, cervix low down in vagina. The mass fills Douglas's pouch.

October 11th—Operation: Under gas and ether the abdomen was opened in the middle line from umbilicus to pubes, a large myoma uteri turned out about the size of a foetal head at full term, peritoneal flaps were dissected down in front and behind, right appendages and ovary being left attached to the uterus. The left ovary was allowed to remain. The neck was severed above the os and within the flaps, the uterine arteries then caught and tied. A further wedge-shaped piece was cut from the neck, to admit the surface above being sewn together by means of three sutures of catgut. The peritoneal flaps were carefully stitched together with catgut, no blood was lost, the pelvis was dry cleaned, the omentum carefully placed, and the abdominal wound united by single rows of silkworm gut sutures. On the ninth day, October 20th, stitches were removed, patient had no marked rise of temperature, and her convalescence was uninterrupted. The ovary removed was cystic, the left ovary which remained was normal.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, NOVEMBER 9TH, 1899.

The President, Dr. MACNAUGHTON-JONES, in the Chair.

SPECIMENS.

Dr. HERBERT SNOW showed the specimen from an unsuccessful case of Hysterectomy for Myoma, the notes whereof will be found under the head of "Original Communications."

Dr. F. A. PURCELL showed a Myomatous Uterus removed by Subperitoneal Hysterectomy. The notes of the case are published under the head of "Clinical Records."

Mr. CHARLES RYALL showed a specimen of Uterine Myoma removed by Abdominal Hysterectomy, the details whereof will be found under "Original Communications."

In the discussion on these specimens, Dr. PURCELL said that there was no doubt that Jewesses were not good subjects on which to operate. The late Sir Andrew Clark laid stress on this fact, and used to advise that a Jewess should never be operated on if it could be helped. Dr. Snow had not given any account of the amount of urine passed after the operation; with all the trouble that he had experienced in dealing with the uterine artery, it was quite possible that the ureter might have been kinked, and the cause of death might have been uræmic poisoning. In Mr. Ryall's case the method of dissecting the posterior flap was of great interest; but in his own experience there was usually no special difficulty in this step of the operation. He would suggest that perhaps in Mr. Ryall's case also, the cause of death might have been renal.

Dr. MANSELL MOULLIN agreed with Dr. Snow that suture *en masse* was the best method of securing the abdominal wound; but it was still capable of being improved on. There was no object in securing the peritoneum separately; this as well as the skin was well secured by the through and through suture; was advisable, however, to suture the layer of fascia parately, and he thought that this was best done by interrupted catgut sutures. It was a mistake to sup-

pose that buried sutures strengthened the wound; on the contrary, they were a source of weakness. Catgut was therefore eminently suitable, since it became absorbed as a rule in four days. It was, as a matter of fact, during the first forty-eight hours that the sutures were most necessary.

Dr. HERWOOD SMITH did not agree with Dr. Mansell Moullin's views as to the best method of suturing. With one layer of sutures, hernia was formerly a not infrequent complication; but since the introduction of three layers this accident had been of much rarer occurrence. It was not advisable to sew the peritoneum with catgut, because peritoneum was best secured with a fine suture, whilst catgut, to be efficient, must be thick. The best material for the peritoneum was fine silk. For the middle layer, catgut answered very well; and for this purpose it gave much less trouble than silkworm gut. He regarded the three-layer method as the typical one for abdominal wounds. With regard to Mr. Ryall's case, he pointed out that in all cases of operation for fibroids there was risk of embolism. But as to the cause of embolism, he thought there were no facts known.

Dr. BEDFORD FENWICK said that they were all agreed that wounded peritoneum united very readily; so that the old idea that failure of healing in the peritoneum might give an opportunity for suppuration in the wound to extend into the abdominal cavity was a fiction. If they put complete sutures through the peritoneum and abdominal wall, the peritoneal surfaces were sure to unite. It seemed to him a fallacy to provide against a theoretical danger by putting interrupted sutures through the peritoneum and leaving them there, and so introducing an actual danger; it was much better to employ sutures which they could remove in seven days. Cases in his practice in which there had been peritonitis seemed to have been due to the buried sutures. True, the peritoneum had a protective action, and might prevent this result; but in other cases it might not. He thought it probable that the danger of ventral hernia might be diminished by the use of a separate suture for the fascia; but it ought to be some absorbable material, and should not remain in the peritoneum as an irritant; consequently, the best material was catgut. He had seen such good results from through and through sutures, that he was loth to believe that there was any advantage in the three or four layer method.

Mr. BOWREMAN JESSETT said that until three or four years ago he always used the single layer of sutures; then he yielded to the fascination of the triple layer method and met with disaster and disappointment; as a rule he had to fish out the sutures afterwards with a crochet hook, even when he had taken the precaution of boiling them immediately before use, because they suppurred. He then went back to the old system. The reason of failure in the old plan was the practice of passing the sutures straight through the abdominal walls; the fascia retracts beyond the muscle, and so often escaped inclusion. The best results were obtained by picking up each layer carefully in one suture. Mr. Ryall's case was very interesting; it was curious how those cases of embolus came about. He had some time ago a case of a lady with a large ovarian cyst; she did well for three weeks and then got an attack of hemiplegia, from which she was still confined in the hospital, though it was twelve months ago. This might also have been due to embolism. Phlegmasia dolens also was common after hysterectomy, but he had not seen a case of embolism of the tibial artery. He did not think it was necessary to form a definite posterior flap, as Mr. Ryall suggested; at any rate when doing a panhysterectomy.

Dr. INGLIS PARSONS said that eight months ago a patient came to him who had had her ovaries removed at a provincial hospital; hernia had followed after a few weeks. She was again operated on, but with a like result. Each time the abdominal wall had been closed with a single layer of sutures. He did not think that this was enough in the case of a patient with thin abdominal walls. He cut out the circular cicatrix, then cut down above the original incision, dissected out the

layers separately, and sewed up the peritoneum with fine silk, the muscles and fascia with silkworm gut, and the skin with silver wire. There had been no return of the hernia since. Dr. Bedford Fenwick and Dr. Mansell Moullin had said that they objected to buried sutures; if thick silk was used, the objection was valid, since it was apt to set up irritation; and for the middle layer he thought that both silk and catgut were unsuitable. With regard to the question of securing the peritoneum, one of his colleagues had a suture abscess some years ago in one of his cases, resulting in infection of the peritoneal cavity and a fatal issue; and he thought this would not have happened if the peritoneum had been sewn up.

Mr. CHARLES RYALL suggested that in Dr. Snow's case the cause of the fatal result might have been traumatic delirium. In his own case, to which Dr. Snow had referred, the first symptom of trouble was shock, from which, however, she rallied, and there was then nothing to show that the wound was at fault. Then shock again supervened, and the wound was found gaping. With regard to the method of suturing it was to be remembered that the suturing of the peritoneum did not add to the strength of the abdominal wall; the object of it was to protect the peritoneal cavity from raw surfaces. To suture the abdominal wall in three layers was anatomically correct; and what was anatomically correct could not be surgically wrong.

The PRESIDENT observed that Dr. Snow had broached a subject of great importance to every operator, viz. the hysterical temperament. His case was typical of this condition, and it was one of the most serious that a surgeon could tackle. In such cases a short operation was specially to be aimed at. He thought that the fatal result must be regarded as an instance of sudden death from vascular disturbance. On the question of sutures many battles had been waged, and at present the war was still going on over material and methods. In America and on the Continent operators with the widest experience had all adopted the plan of sewing up in three layers; and this seemed to him the most workman-like method. For some years past he had given up the single-layer plan; and on only two or three occasions had he had to remove a buried suture on account of suppuration. The peritoneum should be closed for the purpose of protecting the bowel. With regard to operations on Jewesses, it was well known that these patients were very liable to glycosuria; and he believed that under these conditions operations were very dangerous. He had no fear of using silk or catgut for buried sutures, as long as it was aseptic; and he could not agree with Drs. Bedford Fenwick, and Mansell Moullin that a rapidly-absorbable suture was a desideratum; on the contrary, he thought that with such sutures they were more likely to get hernia. While agreeing with Mr. Ryall in the use of the triple layer method, he could not quite endorse his generalisation that what was anatomically correct could not be surgically wrong, for he thought that not uncommonly what was anatomically correct might be surgically inadvisable.

Dr. Snow, in reply, thought that one great objection to the layer-to-layer method was the time it occupied; and this was often an important element in recovery. He agreed with Dr. Bedford Fenwick's remarks on the rapidity of peritoneal union; in a long operation he had seen the peritoneum show signs of uniting before the operation was finished. Mr. Ryall's case illustrated the same point. In reply to Dr. Purcell, he said that uræmia could be excluded in his case, for the bowels and kidneys acted on the day after the operation.

Dr. PURCELL and Mr. RYALL briefly replied.

Mr. BOWREMAN JESSETT showed, for Dr. A. Duke, (1) a new curette; (2) a prehensile forceps.

Dr. R. H. HODGSON read a short communication on "A Case of Tuberculous Peritonitis Simulating Abdominal Tumour, with Operation, followed by Recovery," which we hope to publish next week with the discussion thereon.

Mr. ROBERT BENT BALL, Regius Professor of Surgery in the University of Dublin, has been seriously ill of typhoid fever, but is now able to be out of bed and is steadily recovering.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY. MEETING HELD NOVEMBER 9TH.

The President, Dr. BURGESS, in the Chair.

MR. SIMON SNELL introduced the following cases:— (1) A young woman who had been the subject of tuberculosis of the ocular conjunctiva, illustrating the value of treatment by application of lactic acid. (2) A similar case in a young woman in which the left upper eyelid (inner surface) had been chiefly affected; treated also by lactic acid. (3) A young girl with double papillitis associated with incomplete palsy of both external recti: vision was hardly affected. (4) A man with bilateral palsy of external recti (no optic neuritis), with symptoms of ataxic paraplegia coming on after influenza. (5) A man with a fragment of steel embedded in the left lens.

MR. SIMON SNELL exhibited a number of lantern slides from photographs taken at several large works bearing on the causation and prevention of eye accidents in trades.

Dr. ARTHUR HALL read notes of a case of

ASTHENIC BULBAR PARALYSIS.

The patient, a married lady, æt. 42, began with symptoms of general weakness, was easily tired on slight exertion, could hardly hold a tea-cup to drink out of. This was in November, 1896. One day she fell down in the house, from her legs giving way altogether. About two months after this began, slight ptosis, especially in the left eye, was noticed; there was also some ocular paresis, variable in amount and difficult to estimate. She was apparently free from this in the morning, but as the day went on her symptoms got worse. Except for this muscular weakness, there was no evidence of organic nervous disease. Weir-Mitchell treatment was tried, and the patient improved greatly during a few weeks; but after a somewhat profuse menstrual period she relapsed, and new symptoms were added, notably, a nasal twang in the voice, occasional attacks of dyspepsia, some difficulty in swallowing. One day, some six months from the commencement of her illness, she suddenly turned queer whilst drinking some soup, gradually lost consciousness and died from failure of the respiratory centre a few hours later. At the autopsy nothing abnormal could be found in the brain pons or medulla oblongata. Portions of these were carefully preserved and examined with great care, but no evidence of disease in the nerve cells, fibres, or interstitial tissue was discovered.

Dr. W. N. BARKER read the notes of 22 cases of

POISONING FROM TINNED BEEF

which occurred in Sheffield on October 11th. All who had partaken of the meat suffered, but especially the children, of whom there were twelve. The amounts eaten varied from a piece the size of a hazel nut to ½ lb. The symptoms came on usually about 2½ hours after eating the meat, the onset being marked by drowsiness and giddiness, followed by headache, abdominal pain, profuse vomiting, and diarrhoea. Collapse was a marked feature in the majority of the cases. The treatment was washing out of the stomach, repeated if necessary with stimulants and purgatives. One case died, convulsions occurring before death. Post-mortem, hæmorrhagic erosions in stomach wall and a general hyperæmia of gastro-intestinal tract. All the other cases convalesced rapidly. Dr. Robertson described the meat as looking well, and it had a faint sweetish odour. The bacillus enteritis of Gärtner was found in all the cultures. This bacillus was the active cause in most of the similar reported outbreaks. In this case Dr. Robertson thought the active toxin had been introduced in the meat.

THE Golden Square Hospital for Diseases of the Throat, Nose, and Ear, after undergoing reconstruction and enlargement at a cost of upwards of £10,000, was re-opened last week by Lady Rothschild, whose husband is the President of the institution.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, November 18th, 1899.

THE DIAGNOSIS OF TYPHOID.

At the meeting of the Society for Innere Medizin, Hr. Pierkowski explained his simple process for the rapid determination of typhoid. He uses a preparation of alkaline urine gelatine with an addition of $\frac{1}{2}$ per cent. of peptone, and 2 per cent. of gelatine and cultures, at a temperature of 22 degs. C. After fifteen hours, typhoid bacilli are seen to have developed with long spiral-shaped offshoots; whilst coli bacilli show at the most small pointed offshoots. The proof is available from the third day of the fever to the end. It is important that the urine used should be only slightly alkaline, and the alkalescence is most easily attained by adding a small quantity of urine already become alkaline by standing, to fresh urine.

Hr. Burchardt said that in repeating the test in fourteen cases he had found the colonies in twelve; in two the attempts failed, as the nutrient soil had been too strongly alkaline. In his experience, however, not only the form described by Pierkowski had been developed, but also some with small offshoots. The latter also he saw always with B. coli. In the case of other cocci there were scarcely ever any off-shoots; he saw them once in the case of a boy suffering from angina. The urine gelatine was very suitable for the early diagnosis of typhoid. The reaction, however, gave the earliest certainty. He had seen symbioses of typhoid and coli bacilli.

Hr. Schütze had made use of the test six times in v. Leyden's Klinik, and in five had found Pierkowski's forms. The sixth case showed itself at the post-mortem to be a perimetritic exudate. In one case Pierkowski's process gave a positive result, whilst Widal's did not. It was the case of a woman of 40, with high fever, great prostration, without roseola, and with slight splenic enlargement. Positive diazo reaction and the remittent fever gave rise to a suspicion of typhoid, which Pierkowski's process confirmed, so that its use was to be recommended.

INJECTION OF GELATINE BEFORE OPERATION FOR THE PREVENTION OF HÆMORRHAGE DURING IT.

Dr. Karchesky has an article on the subject in the *Klin. Therapeut. Wochens.*, 37/99. It had already been ascertained that by the injection of gelatine into the peritoneal cavity the coagulability of the blood was much increased. The knowledge was applied practically by the injection of a 1 per cent. to 3 per cent. solution of gelatine in an average quantity of 200 mm. subcutaneously for the purpose of producing coagulation in the dilated walls of an aortic aneurysm. This method of procedure introduced by Lancereaux was followed by the writer, in his case for the prevention of hæmorrhage in large operations. An hour before the operation 200 gms. of a 2 per cent. solution of gelatine in 0.8 per cent. saline fluid were injected subcutaneously into the thigh. The gelatine solution was certainly sterile, and it had been kept in an ice chamber. Previous to using, the gelatine was melted in warm water, and injected by means of a syringe holding 50 grms. The punctures were made some distance from one another

in order to spread out the gelatine over a larger area. After the injection the limb was bandaged to further absorption by pressure. On making the incision the muscular tissues were found to be drier than usual, and they glistened abnormally like wax. The larger arteries and veins bled as before on being severed, the smaller, however, and the capillaries distinctly less, and soft clot was readily formed on the surface of the wound. Examination of the urine at the close of the operation, showed that the gelatine had already entered the circulation. In all cases a heightened temperature was observed.

The practical value of the injection surgically speaking could not be very high.

At the Medical Society Dr. Schuster showed a case of

RECOVERY FROM TETANUS.

The case was of interest, as it had afforded opportunities of trying the different therapeutic measures recommended. The patient, a boy of six, was admitted into Professor Mendel's Klinik in July. The mother, a not very intelligent woman, stated that on the 3rd the boy fell on to a bench on the left side of the head, and from there to the floor. Some days after the face was drawn to the left, and three days later there was trismus. On admission there was no sign of a wound, nor any abrasion. Beyond the spasms there was nothing apparently in the nerves. In addition to the continuous tension, there were spasmodic attacks, which came on about every fifteen minutes, and which could be excited by the least disturbance, such as walking across the floor. The diagnosis of severe tetanus was confirmed; temp. 38 degs. C. On the following day an injection of tetanus antitoxin (Tizoni) was given direct into the dural sac. The operation was not easy owing to the continued movement of the patient. The first visible result of the injection was a rise of temperature to 39 degs. C., and the attacks increased from 50 to 70. The following day the condition was unchanged. The next day the symptoms were much worse, complete asphyxia, dilated pupils not reacting to light. A second injection was made, but no improvement, and a fatal ending was considered certain.

On July 20th, as it seemed as if nothing could do any harm, 10 grms. of pig's brain, emulsified with 30 ccm. of water, were injected into the abdominal wall (Kochiewicz Wasserman and Takaki had shown that brain and spinal marrow substance of most animals had the property of binding the tetanus poison). The operation was well borne; the temperature rose again, however, to 39 degs. C., but the next day improvement set in. On July 28th there were only four attacks, and in the beginning of August the boy was discharged cured. The case was not an absolute proof of the effectiveness of the method, but in view of the desperate nature of the case it encouraged the employment of this form of treatment, especially as the tetanus antitoxin treatment had not come up to expectation. According to Holsti's statistics, of 174 cases, 73 died. In consequence of the want of success the French had proposed other methods, injection of the antitoxin direct into the brain, whilst Jacob injected it into the dural sac, and other authors had proposed to treat the tetanus with other substances that in experiments fixed the tetanus virus.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, November 18th, 1899.

INJURY BY THE RÖNTGEN RAYS.

At the Gesellschaft der Aerzte, Kaposi showed an elderly gentleman suffering from a severe form of dermatitis which had extended over the body after treatment with the Röntgen rays for epilation on the back of the hands. Kaposi said this was not an isolated case, as he had now met with severe forms of erythema, eczema, necrosis, and gangrene after treatment by the rays. Many of these diseases are aggravated and complicated by this treatment within four weeks after the application, when transplantation has often to be resorted to before the patient can be cured. The histological examination demonstrated severe injury to the tissues, particularly the vascular constituents.

Notwithstanding the success of Schiff and Freund in the treatment of syphilis and favus, Kaposi thinks that these dangers should be borne in mind when treating these conditions by the Röntgen rays. Schiff tells us that out of eighty cases he has only had one which has gone wrong. This admission in an enthusiast is in itself sufficient to prove that there is danger in the treatment.

Benedikt thought the Röntgen rays were safe enough as a diagnostic agent, but dangerous as a therapeutic factor, and should not be used unless under special circumstances.

Kaposi said that he hoped none of the members would believe that he condemned the rays in diagnostic investigation.

AN UNUSUAL FORM OF SYPHILIS.

At the Medical "Club" Reines exhibited a patient who had acquired syphilis four years ago, and a year and a half later had severe tertiary symptoms although carefully treated with specifics. Later on gummatous infiltrations appeared on the left eyebrow which proved refractory to treatment, although he had gone to Lindewiese, where such cases usually improve, with the result that other gummata appeared in the lachrymal sacs. On his return he presented himself at Lany's clinic with a large fluctuating swelling over the left temple which appears to have been the original centre of disturbance, and where a lamella of the bone was found necrosed. Since that time the conditions had very little changed, and all specifics had proved quite useless. He is of opinion that a cure might be effected if nutrition were improved.

ATROPHY OF THE RIGHT ARM AFTER INJURY TO THE LEFT.

Kienböck brought forward a country labourer, æt. 32, who had always enjoyed perfect health till he fell from a cart about the end of August last, the whole distance fallen being only 1½ metre or five feet, but immediately on falling the wheel passed over his left arm, fracturing the humerus at the distal end, with a nasty wound.

For some time after the fall, he lay unconscious on the ground, but after recovering walked home with the assistance of a friend. It should be noted here that nothing was observed to be wrong with the right arm, as no visible injury was sustained nor any trace of weakness present. Strange to say the right arm is now greatly atrophied, more particularly the muscles of

the fingers, so that the movements of the fingers and wrist are greatly diminished.

On the other hand, sensibility is normal, the deeper reflexes exalted, while no injury can be detected in the nervous system. The left, or injured arm is free and mobile about the wrist and fingers without any appearance of atrophy. The patient's own observations are that the right arm began to gradually wither away some time after the injury without any apparent cause, but within the last two weeks had more rapidly gone down.

The first diagnosis of the case would probably be in favour of an ascending nerve injury having produced in the cord a descending neuritis leaving the left arm unaffected, but it is more probable that the case is a chronic form of anterior poliomyelitis with a congenital weakness in the anterior ganglia of the cord. The imperfect development of the muscles of the lower extremities lend confirmation to the latter hypothesis, the injury no doubt having excited the progress of the disease in the right side, but, properly speaking, without other primary lesion to the cord. Such cases are of considerable interest from a forensic point of view, as the injury could not be held to be the real cause of the disease.

Eulenburg and Jolly record similar cases which they attribute to a preceding neuritis or central injury, which was not present in the preceding case.

Special Article.

THE WELLCOME PHYSIOLOGICAL RESEARCH LABORATORIES.

MESSES. BURROUGHS & WELLCOME have just completed some excellent Physiological Research Laboratories at Herne Hill, and last week we had the privilege of inspecting them, an excursion which could not fail to be interesting to a medical visitor, especially as Dr. Dowson, the medical director of the establishment, personally conducted the party over the buildings and grounds, pointing out the particular points of interest.

All the apparatus is of the most modern description, and all the arrangements have been most carefully planned and carried out. Of course cleanliness—surgical cleanliness—is a marked feature of the institution, as it must be if success is to attend any branch or department of bacteriological work. Even the sinks are detached from the benches and walls, so that they are readily accessible for thorough cleansing.

The taps by Baird and Tatlock and Tyler, of Newgate Street are so constructed that even with a large stream of water there is no splashing. An excellent incubator of Hearson's was particularly noticed. It is fitted with a new and ingenious automatic registering valve, so that the temperature is maintained constantly at 37 degs. C., and requires no supervision. An incubator on a very much larger scale has been built in a sort of cellar, which is heated by warm air. Arranged round the room are shelves in tiers for the various cultures; each tier having a different temperature owing to the rarefied warm air being constantly highest, and so providing suitable temperatures for the different cultures.

The researches on animals: chiefly mice, guinea pigs and horses, are of course of the greatest practical interest. One small stable is kept exclusively for horses.

when they just arrive, here they are isolated and kept under observation for a time to make sure they are healthy: this point having been satisfactorily settled, they are then housed in the large stable with stalls for about twenty horses.

Diphtheria toxin was injected into a horse for our benefit, a process which it had already undergone some sixteen times, and this gave us an opportunity of observing the ornate precautions which are observed in operations of this kind. These admirably fitted laboratories with their simple yet thoroughly satisfactory arrangements are calculated to inspire every confidence in the trustworthiness of the products therein prepared. Not indeed that the preparation of serums is the only, or the chief, object of this costly installation. It is pleasing to note that with a public spirit which is rare in connection with commercial undertakings every facility and inducement are offered for studying points—and they are many—which still call urgently for full investigation.

The Operating Theatres.

MIDDLESEX HOSPITAL.

OPERATION FOR PERFORATED GASTRIC ULCER.—Mr. JOHN MURRAY operated on a woman, æt. 18, who had been admitted with symptoms of perforated gastric ulcer. She had suffered for some months from anæmia, and for a fortnight previous to admission had complained of epigastric pain after food. On the evening previous to admission she was suddenly seized with violent pain in the epigastrium. She vomited once; she became profoundly collapsed, with a subnormal temperature. When admitted twelve hours after perforation had occurred, the patient was pale and collapsed; the temperature a few points above normal, pulse 120, respiration entirely thoracic, no apparent movement of the abdominal wall; the woman complained of extreme tenderness of the abdomen most marked in the epigastric, left hypochondriac and left iliac regions; the abdominal wall was rigid; there was no marked distension of the abdomen, the liver dulness was almost entirely obliterated, and there was dulness over the lower part of the abdomen up to a point midway between the umbilicus and the pubes. At the operation an hour after admission an incision five inches long was made in the middle line between the ensiform cartilage and the umbilicus; on opening the abdomen the anterior surface of the stomach was first examined, but was found to be normal; the omentum between the stomach and colon presented an œdematous appearance, and on tearing through it a quantity of fluid escaped from the lesser peritoneal sac; the opening in the omentum was enlarged, and the stomach drawn out of the wound, and its posterior surface carefully examined; there was a good deal of lymph adherent to its surface, and near the lesser curvature towards the cardiac end a small perforation was found partly concealed by lymph, the wall of the stomach at this spot being thickened and indurated. The opening was closed by a double row of Lembert's sutures invaginating the walls of the stomach, and the viscus replaced in the abdomen. No solid particles of food apparently had been extravasated, but a quantity of slightly turbid yellowish fluid was found in the peritoneal cavity,

and there was a considerable amount of inflammation of the peritoneal coat of the intestine. The peritoneal cavity was carefully sponged out; and as a quantity of the fluid was found in the pelvis, a small opening was made between the umbilicus and the pubes to facilitate the thorough cleansing of that part of the abdominal cavity. A glass tube was passed through this opening into the pelvis and the ends of the wound united with a few points of suture. A rubber drainage tube was passed from the upper wound into the lesser peritoneal sac, the wound being then sutured with silkworm gut, the sutures going through the whole thickness of the abdominal wall. The patient was very much collapsed, and a brandy enema was administered before she left the table. Mr. Murray said that the diagnosis in the case seemed perfectly clear; the history of pain after food for a fortnight; the sudden onset of pain in the epigastrium accompanied by the marked collapse, and the loss of liver dulness which he knew was not present until shortly before admission, together with the signs of acute peritonitis, all pointed to perforation of a gastric ulcer. He pointed out that the only difficulty in the operation consisted in finding the perforation; this was due to two causes: first, the position of the perforation; secondly, to the fact that the posterior surface of the stomach was partially covered by lymph. With regard to the closure of the perforation, he thought the method of invaginating the stomach wall by means of Lembert's sutures was infinitely preferable to excision of the ulcer, first of all because of the longer time the latter procedure occupied, together with the additional hemorrhage which excision entails, and secondly, because the results of the former showed that healing readily occurred after simple suture. Moreover, in the present case excision of the ulcer would have been almost impossible, owing to the situation of the lesion. He did not wash out the peritoneal cavity: first, because the condition of the patient was so bad that it was advisable to complete the operation as quickly as possible; secondly, as no solid portions of food had apparently escaped from the stomach, and the contents of the peritoneal cavity consisted only of slightly turbid serum, thorough cleansing of the peritoneum could be effected by sponging. He thought that in these cases it was always advisable to drain the pelvis by means of a tube introduced above the pubes, and that the additional precaution of draining the lesser peritoneal sac was advisable, because in that situation the peritonitis was most marked. In closing the upper wound he employed silkworm gut sutures passed through the whole thickness of the abdominal wall in cases where buried sutures were liable to become infected; he preferred this method, he remarked to that of closing the incision layer by layer, but he considered that closure in three layers was to be recommended in aseptic cases, owing to the less likelihood of the subsequent development of a ventral hernia; hernia was, however, not so likely to occur after wounds above the umbilicus.

WE understand that the Army authorities are taking up a large number of civilian chemists to do the work of the Army Compounders at home, the latter having been sent off to the war. These new hands will receive 5s. 6d. per day.

IDEAL ASYLUMS FOR THE INSANE.

A VERY interesting and appreciative description is given in the *Newcastle Chronicle* of the new asylum extension at Coxlodge. It is satisfactory to see so much public attention given to the latest developments of asylum construction, and the new views which find practical application in the administration of modern asylums. In the article referred to the following statement appears. "A tour through the eight wards is a pleasant experience. It leaves, above everything, the impression of cheerfulness and perfect wholesomeness, and one cannot help feeling that, under such circumstances as these, the lot of the unfortunate inmates is alleviated and lightened so far as all human skill, and care, and consideration, can work to such an end. *In such a place*, surely, the thought of imprisonment can never enter. It is a refuge not a gaol." This is all very interesting and satisfactory so far as it goes, but there can be no question that it is only those who specially inquire into our asylums for the insane who really know anything of the subject. As a matter of fact the greatest ignorance prevails regarding asylums, their internal arrangements, treatment of the patients, and character of the staff. It is much to be regretted that, even in our own profession, there is a great deal of stupid talk, simply because medical men do not take so much interest in the subject as to prompt inquiry on the spot. Ninety-five per cent. of our medical men have never been through the wards of an asylum, and now that insanity has become a compulsory subject of medical instruction, it would appear that some who have had such instruction, have only studied mental disease on the threshold of the asylum, and not in view of its medical environment. Medical superintendents should give post-graduate courses in the wards, and in this way the old prejudice

would be wiped out to a large extent, and it would be seen that asylum medical men are doing as good work in their own department, as in any other department of medicine. From the statement which has already been quoted there is a line not quite correct, viz., "In such a place, surely, the thought of imprisonment can never enter." This statement is too optimistic. It does not take into account that asylums have still locked doors, and that the more intelligent and sensitive patients must realise this and feel the jar of lock and key. Above all things freedom is dear to the insane as well as to the sane, and when we can do without locked doors in asylums (and in some asylums, we must admit, this to some extent has been done) the last lingering association of the olden times will be wiped off the slate of memory. He is a very demented patient, indeed who does not appreciate the sense of freedom, the conditions of home life, and the feeling of liberty. Into the details of the article referred to, we need not enter, for they are details which find repetition in our new asylums. Suffice it to say, that such articles cannot be too widely broadcast, and the public and our profession cannot too soon make themselves more correctly *au fait* with the management of our modern asylums. They have sprung into being without due recognition, and they are veritable hospitals for the insane in the best sense of the term. Newcastle has done well in this matter, and her citizens ought to know it.

THE HOSPITAL QUESTION IN THE ANTIPODES.

THAT the burning question of hospital abuse is growing apace in our Australian colonies has been made more and more apparent of recent years. Its dimensions, however, have reached a size that will come as a surprise to members of the medical profession in Great Britain, who have long had their own troubles of a similar kind. The whole subject has been carefully investigated by Mr. L. Bruck, of Sydney, who has embodied the results of his labour in a pamphlet entitled, "The Uses and Abuses of the Public Hospitals in Australia, Tasmania and New Zealand." While many of the points raised resemble those with which British readers are only too familiar there is a peculiar feature in the Antipodean position arising from the fact that in nearly all cases half the annual cost of hospitals is contributed by Government. Under such circumstances the statement can hardly be wondered at that these institutions are frequently established merely as a blind to induce a medical man to settle in a sparsely-populated district. Five years ago the then Chief Medical Adviser to the New South Wales Government advised that no government assistance should be granted to any hospital unless the Principal Government Medical Officer certified the actual need of such an institution. That simple and obvious precaution has not been taken, so that the inordinate increase of needless hospitals goes on with the aid of public money. This

state of matters is incapable of any serious defence, and it seems to show that in Australia as in Great Britain special medical legislation of the kind is enacted regardless of the interests of views of the profession. It appears that throughout Australasia there is one hospital to every 12,299 persons, an allowance which certainly would seem to be far above the needs of the case, unless, indeed, we are to conclude that the average prosperity of the community has fallen to so low an ebb as to forbid them paying for medical attention. At any rate the case as represented by Mr. Bruck demands the careful consideration of every medical practitioner throughout the whole of the vast area—about seven-eighths of the size of Europe—which is dealt with in his pamphlet. He estimates the value of medical attendance on in and out-patients, including operations, at the great total of £625,741, which sum represents services rendered gratuitously to the community by the profession. Yet medical men appear to be just as anxious to encourage the multiplication of hospitals, and to secure honorary posts in those institutions in Australasia as they are elsewhere. In other words the individual fights for his own hands and ignores the benefits to be derived from combination. The pay system at hospitals flourishes in these colonies, a parasitic plant of evil growth that has done much to sap the honesty of the medical charities in our own country. Most members of the profession here at home will agree with Mr. Bruck's contention that all public hospitals should be absolutely free to all comers, and not one penny ought to be received from the patients. Naturally our professional brethren across the sea will point to the example set by such classical institutions as Guy's, St. Thomas and the London Hospitals, to say nothing of smaller fry in shoals. Perhaps one of the best means of control that could be devised over the hospitals would be to make a medical man's recommendation compulsory to every admission. Pay wards can never be tolerated by general practitioners unless they are permitted to attend patients therein. The out-patient departments in Australasia appear to be no better than our own, and the writer of the article does not hesitate to say that they are "mere mediums for pauperising the people," and further, that "deducting the very poor who are fit subjects for gratuitous treatment, there must be considerably more than half of all the patients who could afford to pay for medical advice and medicine." One hospital at Bulong offers medical attendance and medicine for the modest sum of one shilling a week to all residents in the district within a radius of a mile and a quarter. This scheme, be it remembered, is carried on by means of the Government subsidy previously mentioned, which enables an institution to be conducted on these disreputable lines at the expense of the taxpayers of the Colony. Mr. Bruck is not content with destructive criticism alone, for he concludes with thirty-two practical suggestions. Among the chief suggestions are that the words "for the sick poor" be placed upon every-

thing connected with the hospitals, and "for the destitute poor" in connection with out-patient departments; that a medical man's recommendation be a compulsory condition of admission; that patients' payments be abolished; that any patient found imposing upon a medical charity be prosecuted for obtaining money under false pretences; that accident and emergency patients who can pay for treatment be detained only so long as absolutely necessary; that all public hospitals be carried on by Government; that if boards of management be retained one half of their members shall be chosen from the honorary medical staff of the institution; that no honorary medical officer hold any one post longer than four years." There are other stringent and cogent recommendations made by Mr. Bruck, whose directness are nowhere more strikingly shown than in the concluding advice, which is printed in large type, and runs: "Finally, I most emphatically suggest that subscribers withhold their subscriptions from all those charitable institutions which do not adopt the more important of these suggestions." That passage reveals a thorough-going conviction and belief as to the practical power of the purse that should appeal to our Anglo-Saxon relatives in the Antipodes.

THE TEMPERANCE QUESTION.

It would be interesting and certainly of great value if we could ascertain the views of the medical profession throughout the country on the temperance Question. Some medical men are inclined to consider it from a social, others from a religious, and some from a political, point of view. Taking the clergy as a body we should find some difference of opinion if dealing with it as a religious question; for when the Right Rev. Dr. McGee declared that he would rather see England "free than sober," it is not likely that the Right Rev. the Archbishop of Canterbury would be supported in his views by all the ministers of the Church of England. It does not certainly appear easy to find support, in the Holy Scriptures for teetotalism; and we think that such a question as that of temperance had better be dealt with by the medical profession than by the Church. If we limit the discussion to evidence for and against alcohol, from a medical point of view, we must begin by defining accurately what we mean by the word alcohol. If we intend it to mean strictly the chemical compound (C_4H_8OHO) obtained by the distillation of fermented saccharine fluids we must be careful not to allow liquids such as wine and beer to be treated in the same way as pure alcohol. It is true that they are obtained by the fermentation of compounds containing sugar, yet there is only a small percentage of alcohol, and a great deal more that is not alcohol in them. The teetotalist is one who avoids carefully every fermented liquid on account of its containing alcohol. We might ask him if his views of fermentation would extend to the making of bread, and generally to all forms of fermentation, whatever they may be. If we ask such a man why he objects to

alcohol he would say that it is on account of the evils of drunkenness. That it is a reasonable objection if it is impossible to use fermented liquids in any way without such an effect. Total abstinence according to him is the only way to deal with the evil of drunkenness. It was the plan preached by Mahomet and instilled into the very life of his followers. It is, probably, from seeing the condition of the Mahomedans of to-day, that Dr. McGee preferred freedom to sobriety in this country. But if we admit in this argument that drunkenness is a great evil, it does not follow that we believe that alcohol is nothing but a poison. Opium is a poison, and arsenic, and many others of the gifts presented by Nature for the good of man, and if we turn from them because some poor weak creatures will indulge in excess, are we acting for the best? To what extent are we justified in allowing the lunatic to be at large? Some antivaccinationists, and teetotalers, and anti-opinionists, and other kinds of fanatics are ready to sacrifice themselves to what they think is a noble cause. We see the same spirit in the wild delirium of religious excitement, particularly in some parts of the world; but it is doubtful whether the character of the English people is likely to lapse into any such a pitiable condition. Drunkenness is an evil, but it is well to consider whether the indulgence in any kind of poison is not akin to a concentrated essence ending in suicide. The tendency shown by many to indulge in excess in the use of any such agents as opium or alcohol is, in the opinion of the profession, an evidence of disease, and if the teetotalist hopes to cure the disease by doing nothing but withholding the agent, it must be clearly shown that this plan succeeds. Some of the strict teetotalers belong to the class of people who regard all disease as a divine infliction, which man has no right to contend against, and the medical profession would not be appealed to by them for help to cure any such malady as drunkenness. To leave those free who are suffering from this malady, and are a danger to society, is a question that the medical profession ought to take a great interest in. To put a poison in the way of the feeble and the ignorant is certainly unwise, but to say that we ought never to use the process of fermentation, though of great value to many, is absurd. It is well for us to study somewhat closely the process of fermentation. There is no doubt but that it is impossible to obtain more than a certain percentage of alcohol in any fermented liquid; and that the separation of alcohol by distillation is not a part of that process. The simple fact that alcohol will arrest fermentation, suggests the doubt whether it is wise to use it without great caution. It seems as if it is necessary to deal with alcohol obtained as it is, in a very different way from those liquids which have simply undergone the process of fermentation. "Beer therefore," says one of the best writers on the chemistry of common life, "is food as well as drink. A little beef eaten with it makes up the deficiency in gluten, as compared with milk; so that beef, beer and bread—our characteristic English diet—are most

philosophically put together, at once to strengthen, to sustain, and to stimulate the bodily powers." Surely all sensible men will agree upon the best way of treating those evils against which the temperance reformers are struggling, if they will look at the subject in the way in which we believe most of the members of the medical profession do, though the views of the profession have not yet been expressed. So far as legislation is concerned, the chief point to consider is the sale of liquids containing alcohol, certain restrictions being imposed on those which contain a high percentage, or in which the alcohol is not the simple result of fermentation. All distilled spirits require control, and if this were entrusted to the medical profession, it might simplify matters.

Notes on Current Topics.

A Serious Blunder.

AN extraordinary blunder on the part of a medical man came to light last week at the Cardiff Assizes where a woman was to be tried on a charge of having wilfully murdered her husband. It seems that in the early part of last month her husband was found dead in bed under somewhat unusual circumstances. At the inquest the accused stated that the deceased had been ailing for several days with laboured breathing which mustard plasters failed to relieve. The medical man who had made the post-mortem examination gave evidence to the effect that death was the result of a broken neck caused by a violent blow, of which there were marks behind the ear, and he formally asserted that there were no signs of pneumonia in the lungs, whereupon the woman was arrested on the charge of murder. At the magisterial inquiry which followed, the medical witness repeated his statements, and located the exact spot where the neck had been broken. Subsequently an order was obtained for a re-examination of the body by an expert appointed by the Home Office, who found that there was no trace of a broken neck, while on the other hand there was abundant evidence of death having been due to acute pneumonia. The accused was at once admitted to bail, and the prosecution has since been abandoned. Mr. Justice Bucknill, in ordering her release, expressed himself in very strong terms on the terrible blunder that had been committed by the medical witness who, he urged ought to make every compensation in his power to the unfortunate victim of his carelessness, she having had a narrow escape of her life in consequence thereof. In his lordship's strictures we must all concur but with the feeling of shame and regret which all practitioners of medicine must feel at such an unprecedented occurrence is mingled a certain dose of curiosity as to the possibility of so grotesque an error. A broken neck is not an occult lesion as to the existence whereof there can be any room for uncertainty, and the pneumonic lung is tolerably characteristic. In any event this unhappy and regrettable occurrence cannot fail to emphasise our

oft-reiterated contention that the conduct of post-mortem examinations is quite a special department of medical work for which the training and experience of the average practitioner equip him very imperfectly.

Epidemics and Circulating Libraries.

THE danger which circulating libraries entail to the public at large in times of epidemic is now pretty generally recognised, and sundry plans have been suggested having for object the disinfection of books which have been exposed to infection. Now the disinfection of books by any means short of destruction is practically impossible, and it is high time the sanitary authorities took steps to circumscribe the mischief which books may be the means of causing when infectious disease is prevalent. The Medical Officer of Health is empowered to close schools when this step appears to be indicated in the interest of the public health, and he ought to have the power to prohibit, or at any rate to regulate, the circulation of books. The least that could be done would be to oblige librarians to exact from every applicant for the loan of books to sign a declaration of the freedom of the house from infectious disease, false statements being punishable by fine or imprisonment. We doubt, however, if this plan would work satisfactorily, and it would be far better to prohibit the loan of books altogether for a time. This step would not condemn the inhabitants of the stricken town to intellectual idleness, but it would oblige them to purchase their literature instead of borrowing it, a result which would not excite much opposition, at any rate on the part of publishers. It is hardly necessary to add that the destruction of all books known to have been in an infected house would be an indispensable corollary of these measures of precaution.

The Annual Meeting at the Royal College of Surgeons, England.

THE annual meeting of the Fellows and Members of the Royal College of Surgeons, England, took place at the College on Thursday (16th) last, and about fifty of the "body corporate" were present. Owing to the absence of the President, Sir William MacCormac, the chair was taken by the senior Vice-president, Mr. H. G. Howse. The proceedings were of the usual character, that is to say, after the chairman had drawn attention to the report of the Council for the past year, the ever redoubtable champion of the members' cause, Mr. Joseph Smith, again assumed his accustomed warlike attitude, and "went for" the Council for not agreeing to the oft-repeated claim of the members for direct representation on the governing body of the College. The usual arguments, now hoary from their antiquity, were advanced in favour of this reform, and the usual resolution embodying the wishes of the members in this regard was also, as usual, carried by an overwhelming majority. Sir Thomas Smith rather transferred the responsibility of the Council's refusal of the reform to the Fellows, inasmuch as he stated that upon two occasions the Fellows had been directly appealed to for their

decision in the matter, and in each instance that decision had been in the negative. Personally, it would seem that some members of the Council are favourable to the desire of the members being gratified, but, however this may be, it is quite certain that the time has not yet come when the Council will give way on this much debated point. In one respect, at least, the Council should be chary of granting the reform, for if this contentious matter were removed from the arena of debate, it is quite impossible to say what else the "body corporate" would find to discuss at these annual meetings. A resolution was then passed calling upon the Council to prohibit the Fellows or Members from accepting duty in connection with the medical aid associations. But the Vice-President pointed out that, however unprofessional the holding of such appointments might be, they were not illegal, and serious difficulties would be encountered were the Council to attempt to enforce the suggestions contained in the resolution. The only course, therefore, open to the members of the College was to try and bring the pressure of public opinion to bear on the Legislature with a view to an alteration in the law.

The Side-Saddle.

THE Health Protection Society of Cleveland, U.S.A., have undertaken a campaign against the side-saddle for women which they hold to be injurious, and they advocate the ordinary masculine position on horseback for females. While they are on the war-path they also tilt against the fashionable tall hat corsets, and trailing skirts. If this Society should attain any measure of success in their campaign we shall be greatly surprised, for they are proceeding on the utterly fallacious assumption that the care of the health is the primary object of every intelligent citizen and the lady members of his family, whereas it, in reality, comes low down on the list of objects to be aimed at.

Intercostal Neuralgia.

THE etiology of this common, troublesome, but not very dangerous complaint is ill-understood, but its occasional occurrence in epidemic form has suggested the possibility of its being an acute infectious disease. Although it is not usually attended by any marked depreciation of the general health, the suffering which it entails is often of exceeding severity, and excites suspicions of pleurisy or pneumonia, from which, indeed, it can be distinguished only by very careful clinical investigation. Dr. T. F. Reilly, of New York, recently described an epidemic of the kind which he had observed. His cases were characterised by chilliness and malaise, lasting a few hours, followed by pain along one or more of the intercostal nerves, rapidly increasing in intensity and often associated with a mild febrile movement. In a certain proportion of the cases a herpetic eruption developed along the track of the inflamed nerves or in some other situation. Obstinate constipation was a marked feature in all, and in none was there the tender spot which is invariably complained of in ordinary inter-

costal neuralgia. He referred to a similar epidemic reported from Germany, where upwards of a hundred cases occurred within a few weeks. Quinine and other drugs failed to afford relief, and strapping of the thorax was the only measure that appeared to reduce the pain. There does not seem to have been any close relationship between the prevalence of this affection and any particular type of weather, and the precise nature of the affection must for the present remain matter for conjecture.

Morphine and Alcohol in the Profession.

In a paper read not long since before the New York State Medical Association by Dr. T. D. Crothers, some startling conclusions were brought forward bearing on the alleged proclivity of medical men to indulgence in morphine and alcohol. The author's averages are arrived at in a rather obscure way, and we do not feel justified in accepting his statement that 10 per cent. of medical men in general are addicted to the morphine habit. In this country, for instance, it is obviously at variance with fact, though, on the other hand, it is possible that the percentage of medical men addicted to the use of alcohol in excess would compensate for the error in respect of morphine. He refers to the fact that of ninety-two victims of the morphia habit treated in a certain German institution, nearly a third belonged to the medical profession, and there really seems to be some ground for the assertion that medical men are, as a class, more addicted to the abusive use of morphine and alcohol, than the members of other professions, and although it is not difficult to explain this proneness it is none the less a very disquieting tendency.

Lactation in a Virgin.

La Medecine Moderne gives publicity to a curious letter addressed to a physician by a young lady under the following circumstances:—The distressed applicant had had charge of an infant six months of age whom it was necessary to wean, a process to which the infant objected in the way that is the wont of infants under similar circumstances. To console her irritable charge she put it to her own breast, which, she adds, were not very voluminous, but in the course of a few days the breasts underwent an increase in size, and to her surprise and uneasiness a fairly copious secretion of milk became manifest, sufficient, with a little assistance, to satisfy the infant, whose health and development left nothing to be desired. Her object in applying to the physician was to ask advice how to put a stop to a condition of things which, she felt, was, to say the least of it, unusual in a virgin. It is not to be supposed that any difficulty was experienced in arresting the secretion, but the substance of the letter appears genuine enough to give it a physiological interest. We remember to have heard of similar occurrences, more or less well authenticated, in non-pregnant females, even of advanced years; indeed, an abundant lacteal secretion has actually been noted in the newly-born, even of the male sex.

Bird's Eye Statistics.

DR. SYMONS, the Medical Officer of Health for Bath, has adopted a method of formulating his death-rates that is worthy of a passing note by those who are concerned in either drawing up or in reading such documents. His plan is to issue a short comparative list by which the relations of Bath mortality to that of other parts of the United Kingdom may be seen at a glance. Thus, for example, the death rates per thousand annually of all ages for all causes alone and for zymotic causes is recorded for the two weeks ending October 28th and November 4th. This is first given for the 33 great towns at 21.1 and 18.5 general, and 2.2 and 2 zymotic. The lowest in the first week was at Cardiff, with the remarkable figure of 10.1 and zymotic 0.3; for the second week, lowest at Derby, with 11.3, and no zymotic. London showed 21.1 general and 2.0 zymotic during the first week, and 18.6 general, 1.6 zymotic during the second week, and, as one might expect, this nearly approached the total average. The highest rate for the first week at Bristol, which reached 29.7 with 1.9 zymotic, and for the second week at Bolton, which registered 25.7 and 3.5. After this it is an easy task to estimate the significance of the Bath crude death rate, which has no zymotic and gives, 18.8 and 20.8 for the respective weeks, or when corrected 15.8 and 16.7. A similar comparative method is adopted by Dr. Symons in his quarterly returns of zymotic and infantile mortality. Statistics, although doubtless, full of interest and value, are usually presented in undigested form and any attempt to furnish results in a readily understandable summary is worthy of all commendation. Bath appears to occupy a most enviable position as regards general healthiness, and has acted wisely in securing the "whole time" services of an energetic Medical Officer of Health.

The Infantile Death-Rate in Cheshire.

THE Cheshire Council has been much exercised over the infantile death-rate and high general mortality in the boroughs of Hyde, Stalybridge and Dukinfield. The Public Health Committee sent in a resolution, afterwards withdrawn, to call the attention of the Local Government Board to that point, as well as to certain insanitary conditions prevailing in the three districts mentioned and the absence therein of isolation hospital accommodation. The chief point to be noted with regard to the insanitary conditions is that they had been under report for the past five years. So far as the infantile mortality is concerned the lot of Cheshire much resembles that of the rest of the United Kingdom, the inhabitants whereof have grown accustomed to the ever present massacre of the innocents going on in our midst. The causes of this lamentable waste of human life are manifold. Artificial feeding accounts for a great deal of the damage, and insanitary environments, especially by its indirect contamination of milk, may be credited with more. Summer diarrhoea, which is a filth disease of mixed microbial origin, should materially lessen before a rigidly enforced hygiene of milk.

Then there is overcrowding, which flings its bane over almost every domestic condition, including ventilation, the storage of food, close contact of sick and healthy, spread of infection and other equally important contributory causes of infantile mortality. It may be broadly asserted that the greater amount of that destruction is preventable. Science is gradually bringing within her grasp the exact causes of the evil, and it is to be hoped that some day in a not very distant future the raising of the general standard of intelligence will put an end to this great reproach of modern civilisation.

A Nefarious Trade.

THE magistrate at the Thames Police Court last week was called upon to deal with a case which threw a lurid light upon "tricks of the trade." The prosecution was undertaken by the Poplar Board of Works, and the defendant was a man whose occupation was that of selling bad condensed milk for human consumption to a pastry cook. In all he disposed of 385 tins to the latter, and further investigation revealed the disturbing fact that millions of tins of bad condensed milk were stored in a warehouse in Barking. In the course of the proceedings the pastry cook admitted that it was usual in his trade to pay a very low price for condensed milk. The price in this instance was a halfpenny a tin, or three shillings and sixpence for a case of seventy-two, while the proper price of such would be from eleven shillings and ninepence to fifteen shillings. Thus a considerable profit can be made out of tins containing unsound condensed milk, and apparently there is a ready market for them. This being the case, the local authorities throughout the metropolis should keep an eye upon the pastrycooks in their respective districts. Apart from the gross fraud practised upon the public by the use of such an unwholesome addition to our food supplies, it cannot fail to be deleterious to the health, and provocative in all probability of dyspepsia or other intestinal irritation. It is satisfactory to record that the substantial fine of £50 and ten guineas costs was imposed upon the defendant, or in default, three months' imprisonment. To deal leniently with a case of this kind would be simply to place a premium upon the fraudulent practice, whereas to exact a heavy penalty is likely to act as a deterrent in the prevention of its repetition.

The Operative Treatment of High Myopia.

PROFESSOR SILEX, of Berlin, stated at the Utrecht Congress of Ophthalmology that the method of treating high myopia by removal of the transparent lens should in his opinion only be resorted to with caution, as much mischief might be caused by it. During a period of nine months in Berlin he had observed twenty-three cases of detached retina after extracting the transparent lens, while during the same period he had only met with three detached retina in non-operated cases. On the other hand, Von Heppel, at the same meeting, expressed his belief that comparing the number of myopes who have been operated upon

with those not operated upon, the detachments of the retina were about equal.

The Members' Gown at the Royal College of Surgeons, England.

By persistently "pegging away," the members of the Royal College of Surgeons have at last been able to persuade the Council to grant them a special gown. It is a little difficult to understand when the gown could be worn by the members. Even the Fellows have found it a very difficult matter to make any use of their gown, so much so, we believe, that probably about 90 per cent. of the Fellows have not the remotest idea what their gown is like. The only occasion upon which the academic apparel can be appropriately worn is, it would seem, at the annual ceremony of the Guild of St. Luke held, in St. Paul's Cathedral. But we question very much whether any Fellow or member would consider it worth his while to incur the expense of obtaining a gown merely for the purpose of enabling him to give it an annual airing in the cathedral of the Metropolis. Therefore, we think, that although the members are now entitled to wear a gown in connection with their diploma, there is reason for doubting whether they will find the privilege of any use to them.

The Toxic Effects of Aniline Dyes.

It is, of course, well known that aniline dyes are virulently toxic. But it is set down that many cases occur in which their virulent effects are not shown. An instance, however, was recently reported in the public press of an American girl who was poisoned by the ink used on typewriter ribbons. She stained her fingers with the ink, and thus conveyed some of the latter to a sore on her upper lip. Acute toxic symptoms subsequently quickly developed, associated with great oedema and pain locally, and a fatal result shortly afterwards ensued. This unfortunate incident should be accepted as a warning by all typists to avoid letting any of the ink in the ribbons come in contact with a sore that may be present upon their skin. Although the rapidity and fatality of the symptoms in the above case rather point to a septic cause, nevertheless it is wise to be careful, especially when, under such circumstances, prevention against accidents is a matter of no difficulty.

Veils and Red Noses.

A GERMAN physician formulates an indictment of the veil as a cause of acne rosacea affecting the nose, and he relates a number of instances in which young women, otherwise in excellent health, developed this distressing condition consequent upon the habit of riding, cycling, &c., in veils. His view is that the lesion is caused by the friction of the skin against the veil, impregnated with moisture from the breath, the effect being exaggerated by the tightness with which it is necessary to attach the veil when indulging in athletic pursuits. The remedy is obviously to abandon the use of the veil or to wear it loose, anointing the nose with lanoline or other suitable lubricant.

International Congress of Malaria.

THE Liverpool School of Tropical Diseases have just embarked upon another new enterprise. The authorities thereof are now making arrangements for the organisation of an International Congress upon the subject of malaria, to be held under the auspices of the school in that town. It is stated that the researches of Major Ronald Ross in connection with malaria have attracted considerable attention in Germany, France, and other countries having possessions in the Tropics, and it is felt that the time has arrived when an international exchange of opinion upon the subject would be generally advantageous. The conference will probably be held early next summer, and from the favourable reception which the proposal has already received, it is anticipated that the attendance will be fully representative of those who have given special attention to investigating malarial and other tropical diseases.

The Presidency of the Royal College of Surgeons, Ireland.

WE noted recently that a movement had been set on foot in Limerick to present to Dr. Thomas Myles, Surgeon to the Richmond Hospital, and Vice-President of the Irish College of Surgeons, a testimonial on the occasion of his election as President, and we now observe that the Limerick Urban Council has resolved to present him with the freedom of the city on that occasion. While congratulating Dr. Myles upon his anticipated honours, we desire to remove a misapprehension which seems to exist. Unless the existing President, Mr. Swan, retires—which we have no reason to think he contemplates doing—Mr. Myles's promotion to the Chair in the College cannot take place until the first Monday in June, 1900, when, without reasonable doubt, he will be elected President, and will be in a position to accept the demonstrations of appreciation offered to him by his native town.

The Dublin Preliminary Examinations.

WE publish elsewhere a note of the results of the examinations of the present month and of October, 1898. For this examination thirty-seven candidates entered, eighteen passed and nineteen were rejected. For the October examination sixty-four candidates entered, thirty-two passed and thirty-two were rejected. Owing to the severity of these examinations the numerical strength of the Medical Student Classes at the Dublin medical schools and hospitals will be considerably reduced for the next few years. Are the General Medical Council aware that many of the rejected candidates at these examinations have no difficulty in finding an "open door" elsewhere, and pass an examination, and have their names registered as medical students? These are the preliminary examinations which the University interest in the General Medical Council have been, in vain, trying to crush out of existence, just as the College of Physicians interest tried, in vain, to crush out their rivals, the Apothecaries' Hall. It is difficult to respect a public body which allows itself to be used in

this way for the benefit of particular educational cliques.

The Operative Treatment of Tuberculous Peritonitis.

THE operative treatment of tuberculous peritonitis has generally been regarded as satisfactory, and yet some figures recently published by Wunderlich refer to a rather high percentage of failures. Out of ten patients operated upon four died within three months, three grew worse, and only three at a subsequent examination were found to be in good health. The recorded cases of tuberculous peritonitis now amount to 500; among those 68·8 per cent. had ascites; 27·2 per cent. adhesions; and in 4 per cent. suppurative occurred. After three years of observation, it was found that recovery had taken place in 23·3 per cent. of the first cases, and in 9·8 per cent. of the second. Of the suppurative cases 9 died out of 20.

The Evil Example of the Leicester Guardians.

THE evil example of the Leicester Board of Guardians in refusing to comply with the Vaccination Act is now being followed by the Luton Board of Guardians. The anti-vaccination section, being strong on the Board, have determined to set the Local Government Board at defiance. By a vote of two to one, they have resolved to terminate the contract with the public vaccinator of Luton, and have also refused to pay the fees of this official. Of course, the central authority will call upon the Guardians to conform with the law, and if the demand be not complied with the same procedure will be adopted to compel compliance, as was put in force at Leicester. It is lamentable that public officials should thus childishly determine to resist authority.

The Opening Meeting of the Dublin University Biological Association.

ON Tuesday, the 28th inst., at 8 p.m., Dr. William R. Dawson will inaugurate, as President, the session of this Association in the front hall at Trinity College, with an address on "The rôle of the Blood Supply in Mental Pleasure and Pain." The speakers at the meeting will include:—William Aldren Turner, M.D., Physician to the Hospital for Epilepsy and Paralysis, Regent's Park, London; Professor D. J. Cunningham, D.Sc., M.D., F.R.S., Professor J. M. Purser, D.Sc., M.D., and Conolly Norman, F.R.C.P.I., Medical Superintendent, Richmond District Asylum.

Drug Trade Contract Trade.

THE tenders presented by drug contractors to Irish Boards of Guardians since the new regulations of the Irish Local Government Board came into force throw much light upon the drug contract system. Under the old system the contractors tendered whatever prices they pleased, and if they had friends on the Board of Guardians no questions were asked. Under the new system the Local Government Board quoted a reasonable maximum price for each article, and invited the contractors to state what discount they would allow

off the official prices. We note that one firm in Dublin has last week obtained a contract by quoting 50 per cent. off list prices, from which we may conceive what a profit may be made on drugs and to how vast an extent the ratepayers were robbed under the old system.

M. BALLAND, the Principal Pharmacist at the Invalides in Paris, has just presented to the Academy of Sciences a communication on the nutritive value of fruits. He finds that of ripe fruits, such as strawberries, raspberries, &c., 72 to 92 per cent. are composed of water. The nitrogenous matter which they contain does not, in some instances, amount to more than 0.25 per cent. of their weight. The most sustaining fruits are nuts, but it is questionable whether they are digested.

PERSONAL.

SIR HUGH BREVOR, Bart., M.D., has been appointed a full Physician at King's College Hospital, London.

MR. EDWARD WILLIAM SCOTT CARMICHAEL, M.B., C.M., was last week elected to the post of Surgical Registrar to the Royal Infirmary, Edinburgh, vacant by the death of Dr. W. M. Hutton.

We regret to learn that Lady Stokes, wife of Sir William Stokes, Professor of Surgery in the Royal College of Surgeons in Ireland, has been dangerously ill with typhoid fever, but, we are glad to say, is now convalescent.

DR. JOSIAH BLOMFIELD has been presented with a cheque for 100 guineas by the Board of Management of the Licensed Victuallers' Asylum, in recognition of his completion of fifty years' service as Medical Officer to the Institution.

We learn that Mr. William I. Wheeler, Surgeon to the City of Dublin Hospital, has been and is still seriously ill of typhoid fever at his residence in Merrion Square, Dublin. It is hoped that his illness will shortly take a turn for the better.

SENIOR ASSISTANT-SURGEONS M. S. A. Caldeira and A. X. Dias, of the Bombay Medical Department, have been promoted to the honorary rank of Captain; and First-class Surgeons H. D. Walker and D. B. Fonseca have been raised to the position of Senior Assistant with the honorary rank of Lieutenant.

It is understood that Mr. Edmund Owen does not intend to seek re-election on the Court of Examiners of the Royal College of Surgeons, England, when his term of office expires in December. Mr. Anderson and Mr. Page go out of office at the same time, but will offer themselves for re-election. Written applications for the office must be sent in before December 6th.

Royal College of Surgeons in Ireland—Dental Examinations

The following candidates have passed the primary part of the examination for the Licence in Dental Surgery of this College:—Mr. E. T. Pasley, Waterford, and Mr. H. Schlegel, Dublin.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

WOMEN DOCTORS IN EDINBURGH.—The female doctors and their supporters in Edinburgh are difficult to please. The infirmary has stretched several points within the last few years in their behalf, but still they hanker after more. They have a medical and a surgical ward allotted to students of their sex exclusively, they have the entry to all the special departments, but they ask for more. They wish to see female clinical tutors appointed to the wards they attend, so that they may have tutorial instruction from those of their own sex. They have just established a nursing home in a square close to the university and infirmary, supplied with three beds for paying patients, and prospectively with a few for women only able to pay nominal fees; while the staff will be entirely confined to women. A guinea a week will be charged in the case of paying patients, only half-a-crown to the others. If the paying beds be constantly in service £150 a year would come in. The lady doctors of Edinburgh had guaranteed £100 *per annum*, and £180 was looked for from the public.

The scheme is commendable so far as it goes, but when the promoters of it proclaim that the reason underlying their action is due to the lack of opportunity given by the infirmary authorities to medical women they are hardly charitable. Do they aspire to the appointment of female residents, female chiefs, female lecturers? If they do their penalties will assuredly surpass any theoretical, sisterly gain, and their opportunities of sitting at the feet of Gamaliels, whose rank accords with the wide range of choice permitted by large numbers of male students in accordance with the monetary return accruing from them, will be exchanged for that of teachers of their own sex, who, if really competent, will not be content with the remuneration afforded.

THE FELLOWS of the Royal College of Surgeons of Edinburgh held their annual dinner on Friday of last week, Dr. Dunsmore, their President, in the chair. A feature of the dinner consisted in the entire absence of all but the loyal items from the toast list, the questionable delights of after-dinner oratory being replaced by contributions from the harmonists, a very clever quartette of part-song singers of local upbringing, and musical interludes supplied by a small orchestra of first-class executants. The result was much appreciated.

BUMBLEDOM AND BIOLOGY.—The Medical Officer of Health for Glasgow recently suggested to the Town Council of that city that it might be useful were provision made for the biological testing of the milk supplied to the citizens from different sources, with the view of ascertaining how far it was contaminated with the bacillus of tuberculosis. An ex-Baillie, when the matter came up before the Council, at once wished to know if the biological testing of milk was not vivisection. After a confused and muddled argument arising from this, a member of the Council became so affected by the thought of the tortures experienced by poor tubercle bacilli, undergoing vivisection that he moved the rejection of the Medical Officer's report. Ultimately, however, one was found to assure the Council Members that no cruelty was intended by the Medical Officer, that it was better that an animal should suffer than man, and so influenced the corporate mind that the suggestion was unanimously agreed to. Even if the tests made use of included the inoculation of a few guinea-pigs and mice, is it not immensely more important that the milk supply of hundreds of thousands of human beings should be proved to be innocuous or dangerous to them, as the case may be, than that a few guinea-pigs inoculated with the milk should be killed whenever they show indisputable signs of tuberculous infection from the milk—the milk, in fact, which the objectors to the trials of the guinea-pig give to their own children, and take themselves, at much the same risk.

An anti-vivisectionist who objects to the practical testing of milk because it may possibly harm an animal, and subjectively cause it to become diseased, cheerfully, we

suppose consents to the similar though not so immediate vivisectioning of his child, because that does not involve the infliction of a prick of a needle, a prick no more painful than his women-folk experience every time they sew a seam.

"THE DECLINE OF SYPHILIS."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—My attention has been drawn to your Leader of November 15th, in which I am reported as having said at Brussels that "in England among the more educated classes syphilis is almost infinitely rare." Of course I never said anything so absurdly untrue. What I did say was, "inherited syphilis, &c." I was arguing in support of the two years before marriage rule, and alleging that it was now generally observed by the class mentioned.

I am, Sir, yours truly,
JONATHAN HUTCHINSON.

15, Cavendish Square, W.,
November 15th, 1899.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The cheery optimism which pervades your leading article under the above heading in your issue of November 15th is surely very misplaced, and your last phrase—"syphilis as a disease has been latterly robbed of a good deal of its terrors, and is progressively on the decline," contains a very dangerous assertion, especially when made in the columns of a medical paper of sixty years' reputation. I have not had the opportunity of reading Mr. Hutchinson's speech at Brussels, but I hope you will allow me to discuss the various points contained in it which are brought forward in your article. I suppose that the mention of deaths from "inherited syphilis" means the infant mortality in children of syphilitic parents, the statistics upon which are very misleading by the fact of their being so difficult to obtain, yet even accepting the statement that this mortality has been reduced in fourteen years in a proportion of from seventeen to twelve, how can Mr. Hutchinson scout the idea that the inheritance of syphilis is a means of reducing the stamina of the race when he acknowledges in the same breath there is a mortality from inherited syphilis, thus showing that a constitutional disease is transmitted to the offspring of the affected parents which may prove fatal, and, if not fatal, may lead to serious complications; is it not much more logical to believe that the stamina of the race is not reduced in late years owing to the fact that the syphilis is not transmitted at all in a large number of cases owing to the parent, the original recipient of the disease, having been cured by our improved methods of treatment, and how much more would this apply to the third generation even if the taint had appeared, and then been eradicated by treatment in the second. On this account inherited syphilis, I am quite willing to admit, is declining, but the same cannot be said of acquired syphilis, and after more than twenty-five years experience I cannot endorse the explicit statement that "among the more educated classes in England syphilis is almost infinitely rare," and "we scarcely ever see it at all," if so, why the account that follows of the pilgrimage of members of the educated classes to Continental health resorts for systematic treatment, which treatment, by the way, is almost always undertaken in the tertiary stage of the disease. The dictum "there is an improvement in the treatment which is likely to be productive of a great diminution in the prevalence of syphilis" would be very true did it say, "prevalence of inherited syphilis and prevalence of tertiary syphilis." I was much astonished at the statement, "in English practice we scarcely see a secondary stage at all, we suppress it

altogether, and this because mercury is administered before secondary symptoms develop." In my opinion no treatment will prevent the appearance of secondary symptoms; in hundreds of cases I have begun the mercury from the very first apparition of the initial lesion, and I have in every case seen the secondary symptoms appear; it seems to me that one might as well hope to suppress by treatment the eruption of small-pox or the rash of scarlet fever. When we consider the difficulty that even the most experienced surgeon has in the diagnosis of venereal sores we must allow that in all probability simple (so inaptly called soft) sores, or even a spot of herpes, in these cases of so-called non-appearance of secondary symptoms may have been mistaken for the initial syphilitic lesion, and treated most unnecessarily with mercury. Now, Sir, comes a phrase in your article with which everyone who has studied syphilis will most heartily agree: "By this means" (i.e., by treatment) "much is done to prevent the manifestations of tertiary symptoms." This, to my mind, and as I have endeavoured to point out over and over again, is the key of the whole position, for the object of the surgeon in the administration of mercury for eighteen months, two years, or even more is to safeguard his patient as far as possible against tertiary symptoms which constitute really the dangerous part of syphilis.

As you very correctly say, the most valuable observations would be based entirely upon hospital practice, and the reason of this is not, as you assert, that it is mainly among the lower orders that the dissemination of syphilis occurs, but because of the greater field of observation, for in my own experience of venereal diseases in hospital patients, and in private cases, there is, *pro ratio*, a higher proportion of syphilis to simple (or soft) sores and gonorrhoea in the latter than in the former. In neither class of my patients, however, have I noticed any decrease of acquired syphilis.

I am Sir, yours truly,
H. DE MERIC.

Duke Street, Portland Place, W.

EXCESSIVE OPERATIVE INTERFERENCE IN APPENDICITIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of October 25th, you refer to a protest of mine against the doctrine that every case of appendicitis should be operated on the moment the diagnosis is made, and that the appendix should be removed in every case. You ask, "whoever in the land of Nicholas Senn advocates operation unless, first, the condition is of itself serious, or second, has recurred on several occasions?" Had you read the debate in the American Medical Association at Denver, in June, 1898, you would have seen that my protest was called out by the stand taken by Dr. Murphy (of button fame) advocating instant operation in every case, the moment the diagnosis of appendicitis was made, and the removal of the appendix in every case. This opinion is shared by Dr. John B. Deaver, Dr. Robert T. Morris, and others. It was against this doctrine that I somewhat vehemently protested. Moreover, as has been amply shown, even the men who advocate it in theory do not practice it in fact.

I am, Sir, yours truly,
1729, Chestnut Street, Philadelphia, W. W. KEEN.
November 7th, 1899.

INCONSISTENCIES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—You rightly consider that an anti-vivisectionist who condones the hunting of tame deer is a little inconsistent, and you ask "Why cannot the anti-vivisectionists try and put a stop to this degraded cruelty, perpetrated in the sacred name of sport?" I am personally acquainted with a great number of anti-vivisectionists, every one of whom views with horror and disgust the adventures of the Queen's Buckhounds, and is using what interest he can exert to put a

stop to them. The Rev. J. Stratton, of Wokingham, Reading, is a prominent worker on our side, and he has for years past devoted much of his time to protesting, by voice and pen, against this scandalous "sport." Tell us what more we can do in the matter and we will do it. But all this has nothing to do with the crusade against what we consider scientific cruelty, and we cannot refuse the support and influence of persons who, while condoning the cruelties of some kinds of sport, are able and willing to help us in what we cannot but feel is a great ethical question. But, Sir, we are all more or less inconsistent on some point or other. Emerson said that "Inconsistency is the bugbear of little minds"; and certainly we should do nothing in the way of progress if we waited till we were all properly consistent in all we do.

I notice that on the same page in which you suggest the rectification of antivivisectionist inconsistency you say that "the whole system [of death certification] is so riddled with inconsistencies and fallacies as to be in not a few instances worthless." I will so far add that the hospital residents "know little and care less about the interests of outside practitioners." This is brave of you and perfectly true. I know something of the ways of the ignorant and supercilious young fellows. They are very inconsistent but they have their uses, and if our hospitals were to be closed till we had reformed their uncultivated ways it would seriously imperil medical education. *Verbum sapienti.*

I am, Sir, yours truly,

EDWARD BERDOE, L.R.C.P.E., M.R.C.S.

London, November 17th, 1899.

Obituary.

DR. REGINALD SOUTHEY, F.R.C.P.

WE regret to have to announce the death of a widely-known and popular member of the profession in the person of Dr. Reginald Southey, F.R.C.P., who died at his residence, Beltringham, Sutton Valence, Kent, on the 8th inst. Dr. Southey was the youngest son of the late Dr. Henry Herbert Southey and nephew of Robert Southey, the poet. Born in 1835, he was educated at Westminster School, whence he proceeded to Christ Church, Oxford, where he graduated B.A. in 1855, M.A. in 1857, M.B. in 1858, and M.D. in 1866. At Oxford he obtained a first-class in the honour school of Natural Science, and was appointed a Radcliffe Travelling Scholar. He became a member of the Royal College of Physicians in London in 1860, and was elected to the Fellowship in 1866. He delivered the Goulstonian lectures before the College in 1867 and the Lumleian lectures in 1881. Dr. Southey was formerly physician and lecturer on forensic medicine and hygiene to St. Bartholomew's Hospital. In 1883 he was appointed, on the retirement of Dr. Nairne, a Commissioner in Lunacy, an office which he retained until about a year ago. He was the author of "The Nature and Affinities of Tubercle" and "The History of Bright's Disease," and contributed various papers to the St. Bartholomew's Hospital reports, the transactions of the Royal, Medico-Chirurgical, Clinical, and Pathological Societies, and translated Vol. XIV. of Ziemssen's "Cyclopaedia of Practical Medicine."

Laboratory Notes.

BRAND'S NUTRIENT POWDERS.

(Prepared by Messrs. Brand and Co., Mayfair.)

THIS powder is claimed to be prepared from "muscle fibre only, from which the moisture has been removed at a temperature below the coagulation point of the muscle proteins. It is sterilised and tasteless, and is rapidly and easily digestible. It contains all the constituents of lean meat in an unaltered condition."

The statement as to its rapidity and ease of digestion is one that must be left to medical men to ascertain by actual use, though we entertain no doubt on this point, as the other statements of the manufacturers are com-

pletely borne out by the figures that we have obtained on analysis, which are as follows:—

Moisture	11.0 parts.
Dried solids	89.0 "

in 100 parts.

The composition of the dried solids shows them to consist practically entirely of flesh and bone-forming constituents, that is to say,

Albumenoids	82.5 per cent.
Mineral matter	4.5 "

The mineral matter consists almost entirely of phosphates of calcium and potassium, and is free from added salt, which is a far too frequent addition to many of the ordinary meat preparations. On treating some of the powder with water, filtering and then heating the aqueous solution, we obtained a considerable precipitate of albuminous matter.

It will at once be admitted by those who are familiar with the examination of meat preparations, that this is an ideal way of presenting the entire and unaltered constituents of lean meat, and we have the fullest confidence in commending this preparation to medical men.

Literature.

NORRIS AND OLIVER ON DISEASES OF THE EYE. (a)

THIS monumental work, of which the present volume forms the third, is a credit to editors and publishers alike. Nothing of the kind on this special subject has ever been attempted before, and the enterprise which has been shown in its production is deserving of the commendation of the ophthalmological world. The following is the list of local diseases dealt with:—"Diseases of the orbit," "diseases of the eyelids," "operations performed upon the eyelids," "diseases of the lacrymal apparatus," "diseases of the conjunctiva and sclera," "diseases of the iris and ciliary body," "diseases of the choroid and vitreous," "diseases of the retina," "the anatomy of staphyloma posticum and the relationship of the condition to myopia," "diseases of the optic nerve," "glaucoma," "wounds and injuries of the eyeball and its appendages," "sympathetic ophthalmia." In addition a chapter is added upon "Operations usually performed in eye surgery." Thus it will be gathered that in this list there are two important omissions, namely, injuries and diseases of the cornea and cataract. Presumably for some editorial reason, the articles upon these subjects have been reserved until the concluding volume of the work. We have not space to enter upon a detailed criticism of this volume, suffice it, however, to say that all the articles are up-to-date, and worthy of their contributors, and that the reputation of the "system" already attained by the previous volumes is in this well maintained.

ELLISON'S MASSAGE. (b)

WE have read over this volume of 124 pages with much pleasure, and it would appear that the author had in view the intention of providing a short summary of the elementary knowledge necessary for those beginning the study of massage. The subject is divided into twelve chapters of carefully-written matter. A medical preface has been written by Dr. H. H. Hulbert, Medical Officer of the School of Physical Health Culture, London, in which he states he has carefully read through the chapters on the anatomy and physiology of the body, and have found these an embodiment of simplicity, clearness, and accuracy. The whole work is evidently

(a) "System of Diseases of the Eye." By American, British, Dutch, French, German, and Spanish authors. Edited by William F. Norris, A.M., M.D., and Charles A. Oliver, A.M., M.D. Philadelphia, U.S.A. Volume III. Local Diseases, Glaucoma, Wounds, and Injuries, Operations. With 50 full-page plates, and 186 text illustrations. London and Philadelphia: J. B. Lippincott Company (no date).

(b) "A Manual for Students of Massage." By M. A. Ellison, L.O.S., Member of the Society of Trained Masseuses. London: Baillière, Tindall, and Cox. 1899. Price 3s. 6d.

the outcome of diligence and perseverance in overcoming the many difficulties which necessarily attend the study of both the theoretical and practical sides of massage. We have read and reviewed many works on this important subject, and we have an idea that the enthusiastic authors of such books very often imagine that massage is a "cure all" in every disease under the sun. This we feel justified in saying by way of warning is not the case. However, anyone wishing to get a good practical knowledge of the subject will do well to peruse the pages of this little work before us.

CLARKE'S ORTHOPÆDIC SURGERY. (a)

It is to be regretted that so many practitioners are unaware of the simplest rules in connection with this important branch of surgery. When a case of either congenital or acquired deformity turns up in their practice they invariably give the patient or friends a letter to the nearest instrument-maker with directions to construct an appliance which he thinks suitable for the case. The instrument-maker, as a rule, is quite ignorant of the anatomical or physiological cause of its progress, and of the termination which is likely to occur, and makes a costly instrument or appliance which may appear to be suitable, but in the end goes a short way to effect a cure of the deformity present. Many surgeons of repute may be very skilful in the use of a scalpel, but when their services are required in connection with the suggestion of a mechanical appliance for the cure of a deformity they display a hopeless ignorance of how such an appliance should be constructed or applied. If practitioners would only devote some special attention to this branch of surgery they would not have the profession divided up into so many "specialisms," which may be good or bad, as the case may be, for the public, but it is certainly not to the advantage of the practitioner, who frequently has to confess his ignorance with this branch of his work.

The careful perusal of such a work as that before us might remedy many a defect in our practical knowledge of the subject. At page 4 the author states the reason why he directed his attention to the study of orthopædic surgery.

He says: "When I began my work as surgeon to out-patients I felt the lack of training in orthopædic surgery. For help with simple rachitic deformities I sent for an instrument maker whom I knew to be employed at a large general hospital. I found that he usually made the instruments to fit the deformity, and so to exclude the possibility of any improvement being obtained. For cases of club-foot I sought the assistance of another instrument maker, who had been recommended to me as being employed at a general hospital and a large special hospital for children. This man was always ready to air his views on the anatomy and pathology of the various kinds of club-foot.

"His pathology was grotesque, and the instruments he made were usually wrong in principle."

We have carefully read through this work of nearly 450 pages, and consider the subject has been very fully treated. The illustrations are numerous, and, on the whole, very good. We strongly recommend the work to those interested in this special branch of surgery.

WALTERS' SANATORIA FOR CONSUMPTIVES. (b)

This book appears at a psychological moment, when all the world is keen upon the cure of consumption. Its author has dealt with the whole question of special sanatoria in a systematic and thorough manner, and has then given detailed sketches of individual institutions in different parts of the world. The questions of sites, construction, furniture, general and special hygiene, diet,

exercise, rest, medical supervision, the rôle of fresh air, cost of building and maintenance, are all duly considered. Indeed the book is a mine of information for all who are interested in the subject. The question of the duration of treatment is an important one, and we learn that the practice with regard to that point differs widely in various countries. Thus at Basel a minimum of thirteen weeks is fixed. Three months is a common period abroad, although most medical officers of these sanatoria regard that as scarcely sufficient to train the patient in necessary hygienic methods and to put him on the road to recovery. "At Canigou patients who begin to be home sick are sent home for a time, to return again for further courses of treatment. Dr. Giresse regards this interruption as a concession to human frailty rather than as medically desirable. In some sanatoria quite a different system prevails, the patient staying until he is apparently cured, irrespective of how long he may require. Thus, at Nordrach patients stay until for about twenty examinations no tubercle bacilli have been found in their sputa, and until the injection of their sputa into a guinea-pig (which is next done) does not cause tuberculosis. At Davos and other Alpine sanatoria at least two winters and one summer are advised; in Colorado, too, at least two years' residence is considered necessary. At the Adirondack Cottage Sanatorium patients stay until they are apparently cured; the average stay being six months, and one year nominally the limit." The author thinks that in most cases if a patient has made progress he may be sent back after a few months, with directions for a prompt return in case of relapse. The descriptions of the Sanatoria are helped by numerous illustrations and ground plans, which add much to the practical value of the work, which will doubtless remain for some time the standard book upon this important subject.

Medical News.

British Gynaecological Society.

THE annual dinner of this Society took place on Thursday evening last at the Café Monico, the president, Dr. MacNaughton-Jones in the chair, supported by a large gathering of Fellows and many distinguished guests. The toast of the guests was responded to by Sir James Dick, Director-General R.A.M.C., who defended the medical department of the Army, and by Surgeon-General Jamieson, who, in a humorous speech, said he had had some experience of gynaecology himself when in Canada, where he was in medical charge of a regiment of 500 men, with 500 wives and 1,200 children. He referred to modern improvements in the equipment of the army medical department, of which Mr. Makins, before leaving, had remarked that he could find no addition to suggest except a few nail-brushes. He remarked that the suggestion for the employment of civil surgeons in the field had emanated from himself, so it could hardly be construed as a reflection on the department. He referred to the incidence of enteric fever, and mentioned incidentally that they had made a series of observations at Netley on the value of the various filters in the market, and only two had been found worthy of confidence, viz., the L'asteur-Chamberland, and the Berkefeld filters. He called attention to the experiments that were being carried on with anti-typhoid inoculations adding that while the mortality among the vaccinated was only 7 per cent., that among the unprotected was about double, the conditions being the same in the two series. Dr. F. Roberts, the president of the Medical Society of London, humorously remarked that if there had been a gynaecological society in Canada, there would probably not have been 1,200 children. He asked why if the Government thought it necessary to send out civil surgeons to the war they did not also send civil physicians, seeing that the bulk of the mortality in warfare was generally from disease rather than injury. The toast of the Society was responded to by Sir James Crichton Browne in a

(a) "Orthopædic Surgery: A Text-Book of the Pathology and Treatment of Deformities." By J. Jackson Clarke, M.B. Lond., F.R.C.S., Surgeon to the Out-Patients at the North-West London Hospital; Surgeon to the Orthopædic Hospital. With 309 illustrations. London: Cassell and Company, Limited. 1899.

characteristically amusing speech, in which he fully admitted the excellent work that had been done, and was being done, by it. An excellent selection of vocal music and recitations agreeably filled the intervals between the toasts, and the proceedings were continued until a late hour.

Royal Medical and Chirurgical Society.

THE Fellows' dinner of this society was given at the Whitehall Rooms, Hotel Metropole, on Saturday last, the President, Mr. Thomas Bryant, in the chair, supported by the Bishop of London and a number of guests representing the sister societies, the Royal Colleges, &c. The toast of the guests was proposed in a singularly felicitous speech by Dr. Pye-Smith, and was responded to by the Bishop of London who, in a happy vein, referred to the many points of contact between medical and clerical work. The President of the Royal College of Physicians of London also replied. The toast-list closed with that of the Chairman, proposed by Mr. Timothy Holmes, which was enthusiastically drunk. Dr. Beavor and Dr. Habershon contributed some vocal music, and Dr. G. Ogilvie some racy Scotch and other stories, which were listened to with great interest.

Seventh International Otolological Congress.

WE are asked by the Honorary Secretary to announce that owing to the date for holding the International Medical Congress falling in 1903, it has been decided that the next International Otolological Congress will be held in 1902. The meeting will be held at Bordeaux under the presidency of Dr. Moure.

The Mortality of Foreign Cities.

THE following are the latest official returns, and represent the last weekly death-rate per 1,000 of several of the populations:—Calcutta —, Bombay 49, Madras 38, Paris 18, Brussels 16, Amsterdam 13, Rotterdam 18, The Hague 17, Copenhagen 15, Stockholm 17, Christiania 17, St. Petersburg 19, Moscow —, Hamburg 15, Dresden 16, Breslau 21, Munich 24, Vienna 16, Prague 21, Budapest 19, Trieste 27, Rome 15, Turin (10 days) 13, Venice 17, Cairo 31, Alexandria 27, New York (including Brooklyn) —, Philadelphia 15.

The Tallerman Free Institute Trust.

UNDER the above title a new medical charity was formally brought into existence last week at the Langham Hotel, Portland Place, London. Its ends and aims are simplicity itself, and more than justify the launching of a scheme that bids fair to bring valuable relief within the reach of the poor throughout the length and breadth of the United Kingdom. As most of our readers probably know, the special treatment introduced by Mr. Tallerman consists in the local application of air superheated to a temperature varying from 250 deg. F. to 300 deg. F. Although the heat is applied to a limited part of the body the beneficial effects are shown upon the whole system. The results in chronic, rheumatic and gouty conditions is remarkable, and still more so in the mixed or rheumatoid or osteo-arthritis types. For some years past a few charitably-disposed persons have applied an apparatus given them by the inventor to poor inhabitants of a densely-populated South London district. A mission room was borrowed for the purpose, and the cost of the undertaking has been merely nominal. It has occurred to Mr. Tallerman that the poor of the United Kingdom might be benefited by the extension of a similar system of free institutes. He has accordingly called together an influential, general and executive committee to assist in carrying out that intention, and has generously offered to provide free of all cost the necessary apparatus. It is clear that the proposal is fraught with blessing for the crippled and suffering poor of Great Britain, for upon them falls the brunt of diseases of the osteo-arthritis type. The suggestion is that local committees be formed in the chief provincial towns by prominent clergymen and citizens, and that each one appoint an honorary medical officer, who will determine the eligibility or otherwise of candidates for relief. The charity is meant solely for the necessitous poor. Responsible applications from medical men and clergymen wishing to undertake the

formation of local centres may be sent, accompanied with full particulars, addressed, The Tallerman Free Institute Trust, under cover of the Editor, MEDICAL PRESS AND CIRCULAR. It is only fair to state that Mr. Tallerman has not advertised his treatment in lay papers, and always worked loyally with the medical profession, whose support he certainly appears to merit in his new philanthropic departure.

Vital Statistics.

THE deaths registered last week in thirty-six great towns of England and Wales corresponded to an annual rate of 18.0 per 1,000 of their aggregate population, which is estimated at 11,404,408 persons in the middle of this year:—

Birkenhead 19, Birmingham 19, Blackburn 24, Bolton 16, Bradford 16, Brighton 14, Bristol 24, Burnley 16, Cardiff 16, Croydon 10, Derby 10, Dublin 37, Edinburgh 17, Glasgow 17, Gateshead 15, Halifax 10, Huddersfield 13, Hull 16, Leeds 20, Leicester 20, Liverpool 25, London 17, Manchester 19, Newcastle-on-Tyne 16, Norwich 17, Nottingham 18, Oldham 19, Plymouth 17, Portsmouth 17, Preston 18, Salford 19, Sheffield 16, Sunderland 18, Swansea 11, West Ham 14, Wolverhampton 20. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From measles 1.1 in Bradford, and 2.7 in Birkenhead; from scarlet fever, 1.1 in Oldham; from whooping cough, 1.0 in Salford; from fever, 1.2 in Wolverhampton and in Sheffield, and 2.0 in Nottingham. In none of the large towns did the death-rate from diarrhoea reach 1.0 per 1,000. The 142 deaths from diphtheria included 68 in London, 10 in Sheffield, 7 in Leeds, 7 in Leicester, 6 in West Ham, 6 in Liverpool, 5 each in Portsmouth, Birmingham, Manchester and Blackburn, and 3 (each in Dublin, Glasgow, and Brighton). Two deaths from small-pox were registered in Hull, but not one in any other of the other large towns.

PASS LISTS.

Public Health Examinations of the Colleges of Physicians and Surgeons in Ireland.

THE following gentlemen have passed the examination for the Conjoint Diploma in Public Health of these Colleges:—

Honours: Dr. E. J. McWeeney. Pass: Dr. R. H. Draper, Dr. J. J. Earls, Dr. T. W. Heywood, Dr. G. G. Lawson. Passed Part I.: Dr. J. C. McWalter.

Society of Apothecaries of London, November, 1899.

The following candidates passed in:—

Surgery: F. G. Aldrich (Section I.), Charing Cross Hospital; B. Brookes (Section II.), Westminster Hospital; J. M. Edwards (Section I.), Charing Cross Hospital; D. Hamilton, Royal Free Hospital; F. Marriott, Edinburgh; G. G. Mobery (Section I.), Toronto; T. C. Mitchell (Sections I. and II.), Leeds; H. J. Pickering (Sections I. and II.), St. Bartholomew's Hospital; and E. D. Wortley (Sections I. and II.), St. Bartholomew's Hospital.
Medicine: C. B. S. Amos (Section I.), Royal Free Hospital; G. H. Bedford (Section I.), Guy's Hospital; R. F. Ellery (Section II.), St. Bartholomew's Hospital; R. T. Forster (Section I.), Leeds; J. B. Hall (Section II.), Leeds; W. K. S. Hay-Coghan, St. Mary's Hospital; G. G. Mobery (Section I.), Toronto; and T. C. Mitchell (Sections I. and II.), Leeds.
Forensic Medicine: C. B. S. Amos, Royal Free Hospital; G. H. Bedford, Guy's Hospital; T. Burdakin, University College Hospital; E. E. Evans, Royal Free Hospital; R. T. Forster, Leeds; M. P. Gabe, Middlesex Hospital; W. K. S. Hay-Coghan, St. Mary's Hospital; G. G. Mobery, Toronto; and T. C. Mitchell, Leeds.
Midwifery: J. B. Clemens, St. Thomas's and London Hospitals; F. B. Featherstone, Guy's Hospital; R. T. Forster, Leeds; W. K. S. Hay-Coghan, St. Mary's Hospital; H. Jessop, Birmingham; G. L. Parsons, Westminster Hospital; J. E. Pooler, Birmingham; and C. H. Williams, St. Bartholomew's Hospital.
The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—Messrs. M. P. Gabe, D. Hamilton, F. Marriott, T. C. Mitchell, H. J. Pickering, and E. D. Wortley.

The Dublin Colleges—November Preliminary Examination

HONOURS IN ORDER OF MERIT.—J. W. Harvey, M. Campbell, M. J. C. Kennedy.

PASS—ALPHABETICALLY.—J. L. Allen, E. A. Bernard, F. L. Bradish, H. L. Cohen, W. J. Connolly, J. F. Crean, M. B. Fisher, P. E. Harrison, B. Jackson, T. R. N. Miles, J. Murray, J. O'Kelly, E. H. Patman, W. D. Sammon, S. W. Talbot.

Notices to Correspondents, Short Letters, &c.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

A QUESTION FOR WELSH PATHOLOGISTS.

Dr. ROSWELL PARK, of Buffalo New York, writes to a correspondent as follows:—"I ask you to institute an inquiry for me based upon the statement recently made in my hearing by a gentleman who seemed more or less conversant with the Welsh language. We were speaking of appendicitis, and he made the statement that long before this disease was known the Welsh had a common term for the appendix, which was known in their vernacular as the death-trap or death-drop. If this be really so, it would be exceedingly interesting to know just whence the idea came which was thus embodied in so significant an expression."

Perhaps one of our Welsh correspondents may be in a position to help us in the elucidation of this matter.

EX ÆQUALI.—Professor Oster said the other day that instead of proceeding on the Anglo-Saxon principle of considering every fever innocent of typhoid until it was proved guilty, it would be well to try the Gallic plan of considering every fever guilty until it proved that it was innocent of the charge of being typhoid.

SENECTUS.—Our correspondent will find on reference to the report of the trial that the charge was withdrawn.

A FORTIORI.—The power is vested in the hands of the Privy Council.

F.R.C.S.—The system that requires the canvassing of Governors is decidedly objectionable. Unfortunately it is your only vehicle towards the appointment.

M.B.C.P.—Our correspondent will find an action at law decidedly expensive, even if it wrings an apology from the other side. We suggest that an agreement to appoint an arbiter would be a wiser and more satisfactory way of adjusting the difficulty. Above all, we counsel the avoidance of lawyers except as a very last resource.

AGGRIEVED.—Under the Copyright Act of 5 and 6 Will. IV., c. 65, lecturers are protected if, at least two days before the delivery of lectures, their author gives written notice of his claim to two Justices of the Peace living within five miles of the place of delivery. It is highly probable, however, that the law, or the construction of the law, in respect of the copyright in reports of lectures and speeches will be modified.

NEMO.—The rule laid down by Dr. Fordyce Barker was to give iron when the menses are scanty and lack colours, and arsenic when the flow is too frequent, too profuse, or too prolonged.

Meetings of the Societies and Lectures.

WEDNESDAY, NOVEMBER 22ND.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square).—4.30 p.m. Dr. Morgan Dockrell: Benign New Growths. (Post-graduate Course.)

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover Square, W.). 5 p.m. Ordinary meeting, 4.30 p.m. Informal Exhibition of Cases.

THURSDAY, NOVEMBER 23RD.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL (Gray's Inn Road).—5 p.m. Dr. D. Grant: Treatment of Inflammatory and Specific Affections of the Nose.

FRIDAY, NOVEMBER 24TH.

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8.30 p.m. Papers:—Mr. Howard Marsh: A Case of Senile Tuberculosis.—Mr. Arthur E. Barker: A Case of Excision of the Cecum for Carcinoma of the Ileo-Cæcal Valve and Obstruction.—Dr. Chas. W. Chapman: A Case of Obstruction of the Inferior Vena Cava, probably Syphilitic (with Patient).

MEDICAL GRADUATES COLLEGE AND POLYCLINIC (22, Chancery Street, W.C.).—4 p.m. Consultation (Ear and Throat), Dr. Dundas Grant.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Obstetrical Section. Exhibits:—1. Dr. Purefoy, Five Cases of Myomatous Uterus, three Removed by Supra-Vaginal Amputation and two by Pan-Hysterectomy; Four Cases of Ovarian Cyst; Two Multilocular Ovarian Cysts; Two Cases of Cystic Ovary; Two Cases of Pyo-salpinx; Three Ectopic Gestation Sacs: One Case of Carcinoma Uteri; Two Cases of Removal of the Ovaries for Malignant Disease; One Cystic Ovary Removed by Colpotomy; One Calculus Removed from Bladder (size of a walnut).—2. Dr. Alfred Smith, Seven Fibro-Myomatous Uteri Removed by Retro-Peritoneal Hysterectomy: Six Ovarian Cystomata; One Dermoid Cyst; One Pyo-salpinx.—3. Dr. Kidd, Myomatous Uteri Removed by Abdominal Hysterectomy.—4. Dr. Glenn, Coccyx excised for Persistent Coccygodynia due to Dislocation; Case of Tuberculous Tubes: Tube Removed for Salpingitis in a Case of Vento-Fixation for Fixed Retro-Version; Case of Myomatous Uterus Removed by Retro-Peritoneal Hysterectomy; Sac of Umbilical Hernia following labour. Papers:—1. President's Address (Dr. A. V. Macan); 2. Demonstration by Dr. Macan of Laplace's Instrument for Gastro-Enterostomy and Intestinal Anastomosis.—3. Dr. Cole-Baker, Observations on a Successful Case of Caesarian Section.—4. Dr. Purefoy, Case Illustrative of a Rare Form of Ulceration in the Female Urethra.—5. Dr. Kidd, Short Notes on a Case of Wound Called Sarcoma of Ovaries.

TUESDAY, NOVEMBER 28TH.

SOCIETY OF APOTHECARIES (London, at 4 p.m.)—Lecture by Dr. Nestor Tirard on the Pharmacopœia in its Relation to Medical Men.

CLINICAL DEMONSTRATION.—4 p.m. Dr. Fletcher Beach Case of Epilepsy and other Convulsive Disorders.

Vacancies.

Birmingham City Asylum.—Junior Assistant Medical Officer, unmarried. Salary commencing at £100 per annum, with board, apartments, washing, and attendance, &c.
British Hospital, Buenos Aires.—House Surgeon. Salary £200 first year, £250 second, £300 third, with board, lodging, and wine allowance. Apply to Dr. Louis Colbourne, Berkhamsted, Herts.
Ballyshannon Union, Kinlough Dispensary District.—Medical Officer. Salary £100 a year as Medical Officer, and £20 as Medical Officer of Health, together with Vaccination Fees. Applications to J. B. Chism, Clerk of Union. (See Advt.)
Carmarthenshire Infirmary.—Resident Medical Officer. Salary, £100 per annum, with apartments, board, attendance, and washing. Apply to the Secretary, 13, Guildhall Square, Carmarthen.
City Asylum, Nottingham.—Second Assistant Medical Officer, unmarried. Salary £125, with board, apartments, and washing.
County Council of Salop.—County Medical Officer of Health. Salary £750 per annum, to include all travelling and other expenses, except office and stationery. Applications to Mr. E. C. Peele, Shirehall, Shrewsbury.
Devonshire Hospital, Buxton, Derbyshire.—Assistant House Surgeon. Salary £50 per annum, with furnished apartment, board, and washing.
Manchester Royal Infirmary.—Resident Medical Officer for one year, unmarried. Salary £150, with board and residence.
Royal College of Surgeons of England, London.—Three Examiners. (See Advt.)
West Riding Asylum, Wakefield.—Assistant Medical Officer as Locum Tenens. Salary £3 3s. per week, with apartments and board.
Weston-Super-Mare Hospital and Dispensary.—Medical Officer to the Provident Dispensary attached to the Hospital. Salary £90 per annum, with board, lodging, and washing.

Appointments.

BROCKBANK, EDWARD MANSFIELD, M.D. Vict., M.B.C.P. Lond., Honorary Physician to the Ancoats Hospital, Manchester.
FORWARD, E. L. M.B.C.S., L.R.C.P. Lond., Assistant Medical Officer to the Coppice Asylum, Nottingham.
FOX, W. J., L.R.C.P. Irel., L.F.P.S. Glasg. L.A.H., and L.M. Dub., Medical Officer, Medical Officer of Health, Police Surgeon, Public Vaccinator, and Registrar to the Ballinalee Dispensary District of the Granard Union.
HOBSON, H. OVERTON, M.B., C.M. Edin., Junior House Physician to the North-West London Hospital.
MASON, GERALD BOVILL, M.B.C.S., L.R.C.P., Resident Medical Officer to the Ticehurst Asylum, Sussex.
MONTGOMERY, W. P., M.A. Oxon., B.S. & M.B. Lond., F.R.C.S., Honorary Surgeon to the Ancoats Hospital, Manchester.
MOORE, H. C., M.B.C.S., Medical Officer of Health, *pro tem.*, for the Hereford Combined Rural Sanitary District.
ORTON, JOHN, L.R.C.P. Lond., M.B.C.S., D.H.P. Edin., appointed Medical Officer for Foleshill and Stoke, Coventry.
RICHARDSON, I. B., M.B.C.S., L.R.C.P. Lond., Assistant House Physician to the General Hospital, Birmingham.
SAVAGE, SMALLWOOD, M.A., M.B., B.Ch. Oxon., F.R.C.S. Eng., Honorary Surgeon to the Birmingham Lying-in Charity.
WARD, J. P. STEVENS, M.B.C.S., has been appointed to take medical charge of the troops at Crownhill and Woodlands, Plymouth.
WATKINS, D. J. G., M.A. Camb., M.B., B.C., L.R.C.P. Lond., M.B.C.S., Medical Officer of the Lincoln Dispensary.
WESTMACOTT, F. H., F.R.C.S. Eng., Honorary Aural Surgeon to the Manchester Children's Hospital, Pendlebury.

Marriages.

LANKESTER—ARCHIBALD.—On November 14th, at Karachi, Cecil Fryor Lankester, Esq., M.B.C.S., L.R.C.P., of the C.M.S. Hospital, Peshawar, India, youngest son of Henry Lankester, Esq., J.P., of Leicester, to Cecile Florence, second daughter of W. F. A. Archibald, Esq., Master of the Supreme Court, London.
OLSEN—SIBLEY.—On November 16th, at the Old Church, Calcutta, the Rev. C. L. Olsen, M.A., C.M.S., to Edith Mabel Fanny, eldest daughter of the late S. D. Sibley F.R.C.S., of Harley Street.
THORNELY—SMART.—On November 14th, at St. Mary's Church, Bye, William Thornely, M.B., B.C. Cantab., of 60, Herne Hill, S.E., youngest son of the late James Thornely, of Baycliffe, Woolton, Liverpool, to Mary Elizabeth, elder daughter of the late Robert Smart, B.N., of Cranborne, Dorset.

Deaths.

BUCKELL.—On November 9th, at his residence, North Pallant, Chichester, Leonard Buckell, M.D., in the 80th year of his age.
CUBITT.—On November 8th, at Somersby, Castle Hill, Maidenhead, George Robert Cubitt, M.B.C.S., aged 73.
GRAVES.—November 15th, after a long illness, Christine Jessie, the wife of Charles Graves, M.B.C.S., L.R.C.P., of Commercial Road, Portsmouth, aged 28.
JOHNSON.—On November 15th, at his residence, Cliff Bank House, Stoke-upon-Trent, Samuel Johnson, M.D. Ch.M., Medical Officer of Health for the Borough, aged 53 years.
NEWNHAM.—On November 13th, at Margate, Ernest Edmund Newnham, M.B.C.S. and L.S.A., aged 42.

Original Communications.

ON THE PHYSICO-CHEMICAL CHANGES CONCERNED IN THE PRODUCTION OF VERSION OF THE UTERUS. (a)

By JAMES OLIVER, M.D., F.R.S. Edin., F.L.S.
Physician to the Hospital for Women, London.

IN treating of the normal position of the uterus, Quain says: "Its upper end is directed upwards and forwards, the lower downwards and backwards: so that its axis corresponds with that of the inlet of the pelvis and forms an angle or sudden curve with the axis of the vagina which corresponds more nearly with that of the outlet of the cavity." To estimate precisely, and define more accurately, the natural inclination of this organ, is impossible; consequently, it must suffice us to know that the fundus or upper pole which ascends toward the abdominal cavity, should also be directed forwards, and that the cervix or lower pole which projects into the vagina should, to a correlative extent, be directed backwards. Now so long as the integrity, not only of the uterus, but of those tissues on the harmonious relationship of which the maintenance of its rigidity depends, is preserved, the normal position of this organ is not appreciably disturbed by any of the ordinary alterations in the position of the body of the female.

When the bladder or rectum, or both viscera are unduly distended the resulting increased tension and pressure cause the natural inclination of the uterus to become altered, but it is not intended that this organ should, under ordinary circumstances, impose the burthen of its weight upon a neighbour. So too, with regard to the intestines, although portions of the bowel come frequently in contact with the free surface of the uterus, still the latter is not required in the ordinary course of events to aid in supporting the former. Throughout the universe we witness evidence of a cohesive affinity, and it is this agent which no doubt serves to maintain the various organs of the body in position. As the natural direction of the fundus uteri is towards the anterior abdominal wall it is commonly a debatable question whether in any given case the true limit of inclination forward has been exceeded, and the condition should or should not be considered one of anteversion. When, however, the fundus is directed more or less backward it is generally easy to recognise that the inclination of the axis is the reverse of normal, and we are justified in assuming that the change is due to some abnormal state.

The peritoneum which invests the body of the uterus is extended laterally on both sides from the anterior and posterior surfaces of the organ to the

pelvic wall. Included by these folds we find muscular fibres, which are continuous with the superficial muscular layer of the uterus itself; consequently, it is impossible to doubt that the maintenance of the normal inclination of this viscus is in some measure dependent upon the state of integrity of these serous expansions. Some authorities attach much importance to other structures located in the broad ligaments, such as the round ligaments and the ligaments of the ovary, and although these dense fibro-areolar cords do occasionally become sclerosed, yet it is altogether improbable that the position of the uterus is ever materially disturbed by change occurring in these structures alone.

The neck of the uterus is embraced by, and is structurally continuous with, the vagina, which reaches higher up on the cervix uteri behind than in front, a condition of affairs which, together with the inclination of the axis of the outlet of the pelvis, accounts for the uterus assuming so commonly a retroverted position when it is dragged down by volsellum forceps applied either to the anterior or posterior lip of the cervix. Now the vagina is a distensible and highly elastic tube, and by virtue of this elastic property the force of gravitation is so counterpoised that the uterus is not only maintained at a fairly uniform height in the pelvis, but is enabled to descend and ascend in unison with the respiratory movements. This same elastic property of the vagina is a powerful factor in maintaining the natural inclination of the uterus since it opposes those physico-vital qualities which characterise the uterine tissue proper, and are displayed by that portion of the peritoneum which lines the pelvis.

When we remember that rather more than one-half of the weight of our bodies consists of water, it is impossible for us to ignore the fact that this compound plays a most important part in the rôle of the organic economy. It is absolutely necessary for the carrying on of all vital phenomena. The consistence of all the soft structures of our bodies, and the maintenance of their well-being depends to a greater or less extent upon the amount of water which physiologically they are capable of retaining. This, as we know, is not however a fixed quantity. Through the medium of the kidneys, skin, lungs, and bowel, loss of water is perpetually taking place, and this loss must be replaced by fresh aqueous solution. Without this interchange the processes of nutrition would rapidly fail. By the agency of water, nutrient materials in a state of solution are carried to every cell of the body, and waste products are in turn eliminated from the system.

During pregnancy and after parturition, the uterus undergoes a great and somewhat rapid variation in its molecular state, and the changes which take place under such circumstances are effected through the agency of water in consequence of the extraordinary diosmotic power possessed by this viscus. When a retroverted uterus harbours a fecundated and developing ovum it tends spontaneously to assume an erect position about the tenth or twelfth week; it may occasionally even do so as early as the sixth

(a) Paper read before the British Gynæcological Society, November 9th, 1899.

week. Now the pregnant uterus is virtually a growing organ, and we know that growth can only take place when cell tension is well maintained, consequently we are justified in assuming that the alteration in its position is in part attributable to an increased turgescence. I may here remark that the uterus which before conception was retroverted is extremely prone to return to this position after delivery.

It is, of course, very evident that the firmness and rigidity of many organic structures depend to some extent upon turgescence. The stalk of a cut flower, for example, soon loses its rigidity and droops in consequence of a diminution in the cell tension brought about by the loss of water by evaporation; the cell tension may, however, be restored and the structure may thereby regain its rigidity and display once more its erect propensity if we place the cut end of the stalk in water before the cells have unduly lost the power of absorption. When death ensues water is lost by evaporation, and as no renewal takes place organs which in the living state were firm and elastic become more or less limp and flaccid. In the dead body the uterus is very commonly found overlying Douglas's pouch, with its fundus in contact with the rectum, and so generally in fact is this position displayed when sections are made of frozen bodies that some pathologists have gone so far as to affirm that this retroverted position is the natural one. Clinicians have no hesitation in repudiating this assertion, and will no doubt allow that this pathological phenomenon may be attributed to the loss of water by evaporation and other physico-chemical changes consequent upon death, and is determined by the position of the body, which is invariably dorsal.

Elasticity and compressibility are, however, undoubted properties of the uterus, and the maintenance of the natural inclination of this organ is to a greater or less extent dependent upon the preservation and due exercise of these. The aqueous solution we know, which the uterine tissue contains, cannot be compressed by those forces to which it is subjected, consequently the perpetually compressed state—to which we shall refer later—in which the healthy organ exists is not in any way related to the presence of water, although the compressing agent is more or less decidedly influenced by it.

If over the fundus we incise the peritoneal covering of the uterus between the Fallopian tubes, the wound will soon begin to gape on account of the resiliency of the uterine tissue, and the elasticity of the serous membrane. In its natural state, therefore, the uterine tissue is perpetually more or less compressed, and if it were possible to remove entirely the serous capsule without otherwise disturbing the vital state of the organ, the latter would forthwith become more bulky, being freed of its compressing agent.

The peritoneum, as every gynaecologist knows full well, is an extensible and highly elastic structure, but we overlook the fact that that portion of it which envelops the uterus, and enters into the formation of the broad ligaments, exists under ordinary circumstances, and at all times, in a state of passive extension. The elasticity of this portion of the peritoneum is constantly being opposed by the resiliency of the structures which it circumscribes. If, in fact, it were possible to remove intact the serous covering from the uterus without disturbing its physico-vital qualities, it would become so contracted that it probably could never again be made to cover the organ; in other words, the peritoneal covering is virtually too small for the uterus, whilst the uterine tissue proper is, at the same time, too bulky for its capsule. Between these two tissues in their natural connection there exists a mutual tension, and the maintenance of the normal inclination of the uterus

is in a very high degree dependent upon their harmonious action and reaction.

Mutual tissue-tension is a phenomenon displayed by many organic structures, by the tubular flower-stalk of the dandelion, and, notably, by the leaf-stalk of the rhubarb plant. To demonstrate this phenomenon, take a piece of a fresh leaf-stalk from a rhubarb plant and make both ends rectangular to each other. Remove from this a strip of the epidermal tissue, together with the collenchyma layers, which strengthen it, and it will be observed that the strip becomes forthwith so elastically contracted that it is no longer capable of filling up the gap produced by its removal. This shows that in the natural condition the epidermal and collenchyma layers are passively extended. If we now remove the whole of the epidermis from the piece of stalk it is remarked that the remaining structure which consists chiefly of parenchyma, and very extensible vascular bundles has become elongated and altogether more bulky. This shows that the elastic pressure of the epidermis compressed and restrained the natural resiliency of the parenchyma. In the case of the uterus it is highly probable that the shape of the organ favours the action of this mutual tissue-tension.

In the organic world it is difficult to find a structure which is circumstanced like the uterus. The hump, however, on the camel's back bears some analogy. It projects stiffly, is composed chiefly of fat (which, by the way, is but feebly elastic), and is invested by an elastic epidermal membrane. As a rule, it is solid and firm, but it becomes limp and soft when the food is insufficient.

Having summarily dealt with those conditions which determine the natural inclination of the uterus, let us attempt to discuss now those changes in state which may cause this organ to lie more or less passively in the pelvis and assume a position which we are accustomed to speak of as one of version.

The uterus is said to be verted when the body assumes a more or less recumbent posture, the cervix at the same being correlatively displaced in the opposite direction, or, in other words, when the axis of the organ as a whole assumes an inclination which is materially different to that which we recognise as normal. The displacement is specifically designated according to the direction towards which the fundus is deviated, hence we have anteversion, retroversion, right lateral version, and left lateral version.

Retroversion is very commonly noted in association with more or less descent or prolapse of the uterus. Now we are able in some measure, but necessarily very imperfectly, to simulate this pathological state by dragging the cervix down by volsellum forceps, and it is noteworthy that under such circumstances retroversion is very frequently induced, and will persist so long as the traction is maintained. When therefore the elasticity, or in other words the staying and resisting powers of the vaginal canal are more or less markedly impaired, in consequence of defective assimilation and metabolism, or are antagonised and practically annulled by dragging the cervix down it is observed that version, and especially retroversion, of the uterus is apt to result. The reduction to a greater or less extent of that tissue-tension which exists between the cervix and vagina where they are incorporated, and which is a concomitant of prolapse, aids undoubtedly in bringing about an alteration in the natural inclination of the uterus, but the mere descent of the latter organ it would seem, is sufficient to induce this. Virtually the uterus is suspended in the pelvis between two elastic structures, and in their normal state these two in their action oppose and supplement each other. The peritoneum which envelops the uterus, and enters into the formation of the broad ligaments, is elastic, and existing as it does in a state of passive extension,

it exerts constantly a certain amount of pressure upon, and compresses the underlying structures. In this action it is aided by the staying and resisting powers of the vaginal canal; if, however, these become enfeebled, the peritoneum is then so disadvantageously circumstanced that it is rendered practically inert, and it no longer contributes towards maintaining the natural, but favours rather the production of a backward inclination of the uterus.

Turgescence of the uterine tissue proper plays, as has been already remarked, a part in maintaining the natural inclination of the uterus, and it is efficiently preserved so long as the elasticity of the cell walls continues unimpaired, and so long as the aqueous solution in the cells is not unduly diminished, is not reduced beyond what one would term the minimum amount.

Constantly there is a movement of fluid to and from the interior of all living cells, and this diosmotic phenomenon, which depends upon some peculiar property of the cell membrane, is influenced not only by the chemical composition of the cell itself and its contents, but by the character of the liquid which bathes the cells. Normally, the state of turgescence of the uterine and of all other tissues of the body must and does vary from time to time, seeing that the recurring chemical processes necessary for nutrition, and the affinities concerned in depuration are dependent upon the presence, and are effected by the agency of water. So long, however, as the elasticity of the cell wall and the hydrostatic pressure in the cell itself act and react upon each other harmoniously, so long will turgescence aid in maintaining the natural inclination of the uterus.

Under ordinary circumstances, the walls of the cellular elements of the uterus which are kept perpetually on the stretch, more or less, by internal hydrostatic pressure offer some resistance to filtration, and it is evident that the firmness and rigidity of the organ as a whole are in some measure dependent upon this. If, however, this resisting power should be inhibited, a too rapid filtration from the cells will take place and the organ rendered thus more limp and flaccid will tend to assume that position which the resultant of the forces acting upon it may determine. The suddenness with which apparently version of the uterus occurs in consequence of physical or mental shock may be accounted for in this way. In the vegetable world we find instances in which water is rapidly displaced from the cells of a turgescient tissue as a result of a touch or a shake. In this way we can bring about a relaxation of the cells of the motile organs of *Mimosa pudica*, and cause the leaves to move. The leaves of *Dionæa muscipula* (Venus' fly trap) are in like many responsive to contact or shocks. On the inner face of each half of the leaf of this plant are three long fine bristles, and if one of these be touched roughly the two halves of the leaf will approach each other with great rapidity. The shock induces some change in the molecular state of the organic membrane whereby a too rapid filtration takes place, but at present it is impossible to say what may be the nature of this change. Diosmosis is necessarily an obscure and complicated phenomenon, since it depends not only upon the molecular state of the filtering membrane but upon the attractive powers of the materials located within and circulating outside the cells. The excretion of nectar is an osmotic phenomenon, and Dr. H. P. Wilson (Cambr., Mass., U.S.A.) has shown that this excretion may be arrested and held in abeyance for an indefinite length of time by merely washing the external surface of the nectary with plain water, and that when thus suspended it may be re-established by placing a very small particle of sugar on the washed surface. In this case the

exosmotic current is staid by brushing the external surface of the gland with water, but it is forthwith set in motion again by the attraction of the sugar. On reflection it is very evident that osmosis is a phenomenon which may be readily and seriously disordered. Now the nutritive and depurative processes in our bodies are effected by osmosis, consequently any serious derangement of this phenomenon may cause not only an undue diminution in the amount of water in the cells, but may impair more or less markedly the tone of the cellular elements themselves. In the case of a muscular structure like the uterus atony of its cellular elements means impairment of the compressibility and resiliency of the organ as a whole, impairment, i.e., of two properties which aid materially in preserving that mutual tissue-tension which plays such an important part in maintaining the natural inclination of the uterus. If therefore diosmosis should be badly effected then the physico-vital state of the uterine tissue may be so deranged that the organ is no longer enabled to withstand the influence of adverse forces, but tends to assume that inclination which the resultant of these forces may determine.

The mutual tissue-tension to which we have just referred depends, on the one hand, upon the physico-vital properties which characterise healthy uterine tissue, and on the other upon the manner in which the living perimetrium opposes and responds in turn to the influence of these. The perimetrium is an elastic structure which in its natural connection is passively extended. In enucleating solid and cystic tumours from the broad ligaments in emptying a uterus distended with menstrual blood in consequence of an imperforate hymen, and in operating upon the female pelvic organs generally we are constantly and forcibly reminded that the peritoneum which covers the uterus and enters into the formation of the broad ligaments is highly elastic. I desire now to draw your attention to the fact that this quality is often diminished and occasionally it is even entirely lost. In the case of certain cysts of the ovary spontaneous rupture occurs when the elasticity of the peritoneal covering and of the fibrous tissue entering into the formation of such morbid growths is completely destroyed. So, too, rupture of the uterus during pregnancy is due to those chemical changes which induce a loss of this same quality. Ruptures taking place from this cause in the organic world resemble somewhat those which take place in the artificial and growing cells formed by the precipitation membrane of Traube. If, for instance, we drop a small quantity of a concentrated solution of chloride of copper into a vessel containing a solution of yellow prussiate of potash a closed precipitation membrane, an artificial cell, i.e., is instantaneously produced on the contact of the two fluids. The wall of this cell is permeable to water, and this is attracted towards the interior by the chloride of copper which has a great affinity for water. The endosmotic current thus induced causes gradually an increase in the size of the cell, and in the internal hydrostatic pressure. As, however, the cell wall is inelastic it becomes more and more attenuated and eventually it ruptures. Forthwith this breach in the wall is repaired by the coming together of the chemical agents, and so long as unused chloride of copper remains the endosmotic current will continue, consequently these cells may, by the repair of successive ruptures, grow to a considerable size. These artificial cells remain intact until the gradually thinned wall can no longer resist the internal pressure; so, too, in the case of certain cysts of the ovary spontaneous rupture occurs in the same way.

If the elasticity of the perimetrium is greatly impaired or completely destroyed, then that mutual tissue-tension which depends in part upon the

preservation of this quality is annihilated. Such an alteration in the physical state of the uterus causes the organ to become limp and flabby, and renders it less able to withstand the influence of gravitation and other antagonistic forces; consequently, it is extremely liable to assume under such circumstances a more or less recumbent position, a position, *i.e.*, of version. The elastic pressure exerted by the uterine tissue keeps the peritoneum of the mesometrium passively extended, and the tension resulting therefrom augments in turn the staying and resisting powers of the vaginal canal. In this way the normal firmness and natural inclination of the uterus are secured. If, however, the harmony of these tensions and pressures is damaged by any alteration in the physico-chemical state of the structures concerned in their production, then the uterus is less able to withstand the action of adverse forces, and will tend in consequence to assume that inclination which the resultant of these may determine.

A CASE OF TUBERCULOUS PERITONITIS. (a)

By ROBERT HUGH HODGSON, M.D.,
Peckham.

R. F., *Æt.* 9, a female twin child, whose twin sister died in a fit, is one of a family of ten. About two years ago her health commenced to fail, she wasted, lost strength and colour, suffered from constipation, and experienced occasional attacks of abdominal pain. When I saw her in March last she was very emaciated, had a hectic, fluctuating temperature ranging between 99 and 102, and a quick feeble pulse. Her appetite was bad and she had a slight cough. Her abdomen was extremely distended, tympanitic and tender to touch, and she suffered from constant abdominal pains. Her bowels were obstinately constipated. Tuberculous peritonitis was diagnosed. By repeated doses of castor oil the bowels were opened, and by opium and hot poultices the pain was much relieved. The improvement in her symptoms was, however, only temporary. After again relieving the bowels and pain I was enabled to feel the outline of a large tumour, globular in shape, and occupying the left lumbar region. I explained to the parents that although the child was apparently dying from "tuberculous peritonitis" it was just within the bounds of possibility that she had a tumour in her abdomen which was undergoing degenerative change. Wishing to give the child every chance the parents consented to the abdomen being explored. Accordingly ether was administered on May 4th, and the abdomen opened in the middle line, with the result that there was an immediate rush out of about a pint and a half of darkish yellow fluid. The parietal peritoneum was thickly covered with yellow tubercles, and the whole of the intestines were matted together into one round mass, which was situated on the left side and covered with tubercles. The liver was much enlarged. The abdomen was first washed out with hot water, and afterwards with water and carbolic acid in the proportion of 1 in 80, leaving as much in the abdomen as it would hold. The abdominal walls, which were scarcely thicker than brown paper, were united with silkworm gut. The wound healed with exception of the lower end, through which after a fortnight a thin dirty brown fluid commenced to run in small quantities, and which no attempt was made to stop. This discharge continued for four months and then ceased, the lower angle of the wound closing. On the day of operation, and for five days subse-

quently, the temperature remained subnormal, after which it rose for two days to 101, and then fell to normal, and has remained so to the present time. From the date of the operation the pain in the abdomen ceased until about two months ago, since when, with the return of constipation, periodical attacks of pain occur. They are relieved by purging. The abdominal tumour cannot now be felt, and the liver has resumed its natural size, the abdomen is fairly flat, the temperature is normal, there is no cough and no hectic flush. The child has gained a little flesh and is bright and cheerful. During the last month there has been Lienteric diarrhoea, which has now ceased under treatment. Although the improvement is good all round, I have but little hope of a permanent cure, since the emaciation and disease were so far advanced. I have brought this case forward with the double object of showing how the whole of the intestines may be gathered together into one mass simulating a new growth and also in the hope that although the result is far from what one would wish to see, still it may be some inducement to look with more favour upon carbolic acid in large doses, as the drug to at least hold in check active tubercle. The moot points in this case appear to me to be:—

1. What caused the arrest of the tuberculous activity, was it the carbolic, the ether, or the admission of air?

2. Was the amount of carbolic acid left in the abdomen sufficient to cause poisoning?

3. Did the ether counteract the danger of carbolic acid poisoning, and did it intensify the therapeutic action of the carbolic?

4. What caused the increased size of the liver?

1. I think from one's general knowledge of the use of carbolic acid I am justified in attributing the arrest of tuberculous activity to the action of carbolic intensified by the diffusibility the ether imparted to it. Against the statement that the mere admission of air has produced similar results one must set off the possibility of the anæsthetic used being the germicidal agent and its sufficiency in slight cases. One would not open a tuberculous pleura, admit air, and then seal it up without expecting an empyema.

2. Roughly estimated, the amount of carbolic acid left in the abdomen was one drachm, which in the circumstances that the child was very emaciated and in extremis, was, in my opinion, sufficient to cause poisoning. Bearing in mind that the cooling of the body by ether passes off within two days, I think the continued subnormal temperature was probably due to the carbolic, and not to shock, since little was done to cause shock, and that if shock did exist, it was removed by the warm abdominal washing, and the warm fluid left behind.

3. The ether by its stimulating power nullified to a certain extent the paralysis which would otherwise have followed the carbolic acid acting upon the nerve centres.

4. The increased size of the liver I take it was caused directly by the growth of tubercle which could hardly have been reached by a few minutes interchange of air in the abdominal cavity.

I may add that I saw the child again this morning, and my opinion is now more favourable than it was when I wrote these notes; the temperature is perfectly normal, all abdominal pains have ceased, and the bowels act twice daily, and she is decidedly gaining flesh.

Mr. CHARLES LEEDHAM GREEN has been selected by the Director of the Army Medical Department as civil surgeon to the 4th Divisional Hospital in South Africa. Mr. Green is one of the casualty surgeons at the Queen's Hospital, Birmingham. He expects to leave England early next month.

(a) Paper read before the British Gynecological Society, November 9th, 1899.

THE TREATMENT OF ACUTE PSYCHOSES BY REST IN BED.

By DR. P. SÉRIEUX,

Physician to the Asylum for the Insane for the Department of the Seine.

[SPECIALLY TRANSLATED FOR THE MEDICAL PRESS AND CIRCULAR.]

(Concluded from page 526.)

THERE do not seem to be any absolute contraindications to this method of treatment; at most it is possible to point to certain drawbacks associated with its employment. These drawbacks, for the most part quite unimportant, should nevertheless be carefully studied, in order that we may be enabled to obviate them by special measures. To Weir-Mitchell belongs the credit not only of having shown the satisfactory results, both physical and psychical, of the treatment, but also of having pointed out its drawbacks and the way to obviate them. The method employed by the American neurologist has indeed for object, to solve the problem how best to secure for our patients the benefits of rest in bed without any undesirable consequences. Weir-Mitchell insists on the fact that rest in bed diminishes the heart-beats by at least twenty a minute, that is to say, we reduce them approximately by one-third; that the blood circulates languidly through the capillaries; that prolonged rest in bed constipates and tends to abolish appetite, and lastly, that the muscles under too prolonged disuse degenerate and become atrophied.

These undesirable consequences of prolonged rest are overcome by Weir-Mitchell by means of massage and electrophathy. These therapeutical measures, far too much neglected in asylums for the insane are capable of rendering very great service in respect of patients undergoing the treatment by rest in bed. Massage, indeed, obviates most of the evils which are apt to follow prolonged rest, and acts efficaciously on the nutrition of the skin and muscles, on the peripheral circulation, on the temperature, and on the sensitiveness of the skin, exciting a reflex trophic action, like other peripheral stimulants. According to Weir-Mitchell massage is a "delicious sedative." Electrotherapy, employed in the form of the induced current, acts on both the muscles and the skin.

We will now deal briefly with the complications which may be ascribed to prolonged rest. Anorexia is sometimes observed, and in these cases only readily assimilable food should be given, such as milk, beef-tea, soups, egg and milk, mashed vegetables, and minced meat. The food should be given at frequent intervals, but no refusal is to be accepted.

Dyspeptic troubles and gastro-intestinal atony are treated by an appropriate *régime* by general massage, especially directed to the abdominal region.

Constipation, a symptom that is constantly present at the very beginning of the treatment, usually disappears spontaneously after a few days. Should it persist a change of position from the dorsal decubitus to the sitting posture in an arm chair will perhaps have the desired effect, otherwise enemata or mild laxatives must be resorted to.

With respect to hebetude and dirty habits, close looking after of the patient will often suffice. The patient should be taken to the lavatory at a fixed hour, and he should be incited to use the bedpan.

The tendency to masturbation requires constant watching. As a rule it does not constitute a contraindication. Neisser, however, discountenances the treatment for young women suffering but slightly from motor excitement, but who are the subjects of marked sexual erethism.

When the treatment causes anæmia the best

remedy is to wheel the patient on to the veranda, and in certain cases he may be allowed to recline on a sofa in the garden. We have already insisted on the necessity for ample ventilation in wards set apart for this treatment, and the windows should be opened at frequent intervals.

In presence of amyotrophy and stiffness of the joints, electricity, massage, passive movements, Swedish gymnastics, and short walks in the garden are indicated.

It is hardly necessary to insist on the prevention of bedsores and hypostatical pneumonia. These complications, which, moreover, are very rare, can be arrested by proper care of the integument, by daily baths, frequent changes of position, and occasional permission to adopt the sitting posture.

Having completed the description of the technical details of the treatment by rest in bed, its physiological effects, its results and its inconveniences, we shall now proceed to discuss those mental conditions, which we believe to be amenable to this treatment, laying stress on the special points presented by each. All acute psychoses should be treated by rest in bed, and under the heading of "acute states" we understand recent and suddenly developed delirium (toxic and hallucinatory delirium, maniacal and melancholic conditions) and acute outbursts occurring in the course of chronic conditions (general paralysis, circumscribed cerebral lesions, systematic delirium, &c.).

Febrile delirium.—We shall only say a few words in reference to these forms which all develop with great rapidity. Their supervention in the course of an acute, usually infective disease, constitutes an indication for this treatment.

Alcoholic delirium.—We may consider alcoholic delirium as the type of the toxic deliriums. According to Magnan, it is in this mental condition that the treatment yields its best results. The patient with febrile delirium tremens ought to be subjected to this treatment just like any other pyrexial case. This applies equally to simple alcoholic delirium, that is to say, delirium tremens without fever or complications. Constant surveillance, day and night, is indispensable. Rest in bed should not be made a pretext for securing the patient by means of a straight-jacket or other means of ensuring immobility. Bad as this practice is in ordinary cases of excitement, it may prove disastrous in the subjects of alcoholic delirium.

Magnan, who was the first in France to apply this treatment to acute and subacute cases of alcoholism, gives his results as follows:—Alcoholic delirium, which consists almost entirely of illusions, hallucinations, and general sensory troubles, becomes intensified as soon as the patient, isolated in the dark, no longer receives any external sensations. The illusions produced by alcohol are modified by the transmission to the centres of perception of well-defined external impressions. These, being more consonant with actuality, are more vivid and take the place of illusions, which are always more ephemeral, and so they soon change the course of the delirious ideas.

Rest in bed is one of the most powerful therapeutical agents, in that it brings the patient face to face with the reality whenever he recovers himself, and it enables us to dispense, for the most part, with the use of hypnotics. We may add that the rapid evolution of the disturbances due to alcoholic intoxication, both acute and subacute, facilitates recourse to this method.

The Morphine habit.—The chief symptoms in this class of patients which justify the treatment are the deterioration of their physical condition, and the prostration of the organism and the imminent danger of cardiac manifestations. If the patient be subjected to immediate deprivation of the drug, a plan which

daily becomes more popular, he should be kept in bed until the phenomena of morphia intoxication have entirely disappeared.

Mental confusion.—This malady is almost entirely due to exhaustion of the cerebral cortex, a fact which renders this treatment peculiarly appropriate.

Chaslin, who has made a special study of the question, recommends this method of treatment very strongly, inasmuch as the somatic condition of the body is that of a person really ill. The treatment has the advantage of checking further exhaustion, of removing all causes of fatigue; it prevents a chill, and has a sedative action, which action is not without its importance in cases of excitement. Another advantage, this time of a moral character, and therefore included in the psychical treatment, is that the patient, who may have a vague idea of his pathological state, or may have lucid intervals, on finding himself in bed, understands that he is really ill and requires nursing, and this assists in restoring his mental equilibrium and in dissipating the mental confusion.

This treatment, although it plays a very important part in dealing with mental confusion, is not, however, the only therapeutical means at our disposal. The exhaustion of the brain imperatively calls for hyper-alimentation, and in certain cases injections of saline solution will prove beneficial; lastly, the excitement is overcome by a tepid bath or the wet-pack, and depression by alcohol or strychnine.

Acute hallucination.—What has just been said in regard to mental confusion applies equally to acute hallucination, which is a very similar morbid condition. Rest in bed is very effectual when there are hallucinations and it constitutes, indeed, the veritable etiological treatment. In these last two maladies the morbid symptoms are apt to persist for several weeks, sometimes even for several months, so that it becomes difficult to apply the treatment throughout the whole course of the disease. If by the end of six or seven weeks signs of recovery have not shown themselves, the patient should be got out of bed for several hours every afternoon, the continuous treatment being reserved for attacks of intermittent excitement which invariably manifest themselves in the prolonged forms of the disease.

Hysteria.—It was in cases of grave hysteria that Weir-Mitchell applied the method of treatment which bears his name. It is now too well known for it to be necessary for us to discuss its special advantages. Hysteria, during the paroxysms, should be treated by rest in bed, and the attack itself, which may be looked upon as a fit of hyperacute hallucination, constitutes an indication for this treatment. Every precaution must be taken to prevent the patient from injuring herself, but these do not include the use of ligatures, straight jackets, &c, so much in use at Salpêtrière since the time of Georget. The treatment becomes more than ever necessary if the patient becomes confirmedly delirious, for the patient then falls into the category of acute hallucinations, which may culminate in attacks of excitement, hilarious or melancholic, according to circumstances. In special cases, a period of isolation in a room with padded walls may become necessary, the patient being always kept under close observation.

Epilepsy.—Neisser, since the year 1893, has laid stress on the results to be obtained by treating epilepsy by rest in bed. In seven cases of epilepsy under his observation, he states that, under the influence of the treatment, the convulsions diminished in frequency and intensity for about six weeks, the increase in weight being very marked. Schmidt, who has treated excitable epileptics by this method, states that they can be kept in bed without any difficulty, and that they become calmer and more manageable.

The treatment by rest in bed is indicated in delirious outbreaks of an epileptic nature, as in all the acute psychoses, but occasionally serious difficulties present themselves. The most marked cases of excitement are met with in delirious epileptics, consequently a great many authorities abandon the treatment in these cases. If need be padded box-beds on the floor, short periods of isolation with constant watching in padded rooms with the floor covered by mattresses, must be resorted to. Dr. Pochon, in his thesis, describes Magnan's method of treatment. He says: "The possibility of the treatment will depend on the intensity of the excitement. If the patient be violent it is quite useless to insist on this treatment, and an attempt at all hazard to keep the patient in bed would be courting disaster, in such cases isolation must be unhesitatingly had recourse to. In cases of less intense agitation, where the movements of the patient are not so violent, the treatment by rest in bed should be employed. The exhausted condition of the patient following these attacks will thus to some extent be attenuated."

Neurasthenia.—Weir-Mitchell's method of treating neurasthenic patients is described in all treatises on therapeutics, so we need not go into the details.

Maniacal Conditions.—The application of the treatment to cases of maniacal excitement and to violent lunatics, who are always the prey of an unsurmountable proneness to disordered movements appears at first sight impossible. The experience of the last few years, however, has demonstrated the possibility of treating excited patients in this way. It greatly diminishes the intensity and even the duration of the attack, and also obviates complications.

J. P. Falret was the first to recommend this treatment for patients suffering from "certain acute maniacal and semi-febrile conditions." At present the indication for the treatment is not to be sought exclusively in the state of the patient's general health. Excitement *per se* is sufficient to justify resort thereto.

According to Magnan the no-restraint method and the treatment by rest in bed are the two general methods to employ in cases of mania. We quote his description of the application of the treatment in cases of this kind. "The maniacal patient, when in bed, continues, of course, to be restless, to gesticulate, to talk at random, to shout and to sing; he throws away his pillow, his bolster, and discards the blankets and sheets, and is always trying to get up; but in the course of two or three days, though still agitated, he ceases his attempt to leave the bed, and, at any rate, returns promptly on simply being told to do so, in deference to the influence of imitation and example. When in bed, as soon as he can be got to sleep, he is completely at rest, and these hours of sleep go a long way towards expediting recovery. When he wakes, he again starts talking and gesticulating, and he gratifies his instinctive desire for movement by disordered gestures. When the patient is very boisterous and noisy he is not allowed to sleep in the dormitory, but is put into a room with a perforated door so that the attendant can see all over the room. It goes without saying that the patient must be retained in bed without having recourse to any means of physical restraint. The very presence of a nurse at his bedside will usually suffice to keep him from getting up. In certain cases, hypnotics may be employed, especially at the outset when the patient has not as yet become accustomed to being in bed. Generally, however, the avoidance of forcible measures of restraint and recourse to the bed treatment, render it quite exceptional for isolation in a cell to be required. This is not one of its least important advantages: "Bed," says Neisser, "replaces the padded room."

Dr. Toulouse has been the advocate in France of the mixed treatment of prolonged bed treatment varied every day by two hours' walk. The walk relieves the excitement of the maniacal patient as has been recognised in Scotland, where it forms one of the methods of treating the insane. This plan obviates denutrition, and combats the tendency to syncope to which prolonged rest in bed is apt to give rise.

In our hospital, where we practice the bed treatment, we have almost completely abandoned the isolation of patients in special rooms as a means of calming maniacal excitement. Our observations tally with those of Magnan, who asserts that the hyper-acute manifestations of insanity disappear under rest in bed, just as what Esquirol called "maniacal anger" disappeared with the abolition of the straight-jacket.

Bernstein, who has tried the bed-treatment in his hospital service at Moscow, notes the promptness with which most maniacal patients become accustomed to bed, their excitement subsides in a marked degree, and the padded rooms remain unoccupied. We witness no more of the scenes with which we were familiar when the system of isolation was prevalent. "The patients retain their human qualities which degenerated rapidly in former times when the patient was imprisoned in a cell. Imbecility which was inseparable from sojourn in the cells no longer exists." According to this author the treatment does not notably expedite recovery, but on the other hand, Timofeier and Goveier state that it does hasten recovery, in addition to increasing the proportion of cures.

Pochon considers the treatment by rest in bed as both possible and necessary for maniacal patients. The febrile state associated with the onset of the attack, the furred condition of the digestive tract, menstrual troubles and emaciation are sufficient in themselves to require rest in bed for these patients. This method of treatment diminishes the excitement, one no longer meets with the congestive conditions which often culminated in acute delirium and death. Sleep, when it comes, is vastly more recuperatory in bed than on the floor of a cell; the patient is better looked after, he becomes better acquainted with his attendant, and *vice versa*.

Melancholia.—Melancholia in its various forms was one of the earliest mental states to derive advantage from the treatment by rest in bed. It is to these forms that the treatment is now most readily applied. We may add, that in so doing one is often consulting the patient's wishes, for many of them would gladly stay in bed if allowed. In melancholia we find a whole series of symptoms which call for rest in bed, such, for instance, as unsatisfactory general condition, emaciation, due to want of nourishment and to insomnia, cyanosis and œdema of the extremities, and anæmia. Rest in bed is readily agreed to by the majority of these patients. It sometimes happens, however, that a difficulty is experienced in keeping excited melancholics permanently in bed (Paetz and Kraepelin). What has been said of the other psychoses applies equally to melancholic states. Rest in bed dispenses to a great extent with the use of hypnotics, does away with cellular isolation, averts visceral complications, ameliorates the general condition, and at the same time lessens the chances of the attack terminating in dementia, chronic melancholia or death. It also averts many psychical complications such as hallucinations, delirium, which are conduced to by exhaustion and want of sleep.

In certain patients (melancholic, but not delirious, or on the way to recovery), the method need not be applied too vigorously, but in every case the patient should only be allowed to get up after lunch, and should spend the forenoon (which is the worst part of the day for him) in bed.

What we have said concerning rest as a therapeutic agent in the acute psychoses will explain the good results obtained by the treatment in melancholic patients. It is especially rest that the melancholic subject requires. From the physical point of view rest is favourable to the amelioration of the general health, to the loss inflicted on the organism by insomnia, refusal of food and anxiety. The heart beats more regularly and with greater force, the pulse at first small and quick improves (Guissar Muller); cerebral circulation is facilitated by the horizontal position, and consequently the brain is better supplied with blood; the vaso-motor disturbance subsides; loss of heat is avoided, an important point in subjects whose muscular activity is practically *nil*, in whom respiration is comparatively inactive, and in whom temperature is often below normal. The cutaneous functions, which leave so much to be desired, are stimulated by rest in bed, and assist in securing a more general supply of blood to the skin: "under its influence the integument, usually so dry, becomes moist." (Guissain.)

Rest in bed is not less beneficial from the mental point of view. The improvement in the general health is of itself sufficient to explain the attenuation of melancholic symptoms, if we adopt the views of Lange, G. Dumas, and Maurice de Fleury, that depressed states are merely the consciousness of the condition of the body, due to the hypotonus of the non-striated and striated muscles, to the result of want of muscular and cerebral nutrition. Remedying the nutritive disturbances of the brain and of the organism as a whole, we modify the debility which had awakened a distressing echo in the conscient organ.

Rest in bed also exerts a direct influence on the mind not less beneficent in its way. It is well known how vivid is the psychical hyperæsthesia of melancholics, how intolerable the moral agony, and how well marked their inertia. Feeling, thinking, wishing, moving are to such patients all painful forms of cerebral activity.

Rest in bed, as we have seen, diminishes to a great degree visual, auditory, tactile and thermic sensations, suppressing, as it does, all muscular activity in respect of environment: it spares the patient all voluntary acts, all exercises of the will. The patient is thus ensured complete repose. In short, rest in bed ought to be considered as the primary indication in the treatment of melancholic states.

Periodical Psychoses.—We need not dwell on the periodical psychoses. They are similar in all respects to typical melancholia and mania. It frequently happens, in these morbid states, that the patient, recognising the good results he derived from rest in bed during a previous attack, is the first to ask for the treatment when he feels that an attack is imminent. This is one of the best testimonials we can have of the beneficial effects of this method of treatment.

Before concluding, there only remain a few words to be said on the acute periods of chronic psychoses. They are similar to hallucinatory delirium, and, therefore, what we have said concerning mental confusion and acute hallucinations is applicable here.

Chronic Systematic Delirium.—It will be but rarely that the treatment by rest in bed requires to be applied to this class of patients, the more so, as these patients are perfectly conscious, but owing to their mental state interpret every act on the part of their immediate surroundings as an insult; they even refuse to submit to the directions of the physician. Neisser, however, keeps such patients in bed for the first week after admission.

In certain outbursts of hallucination some benefit may be derived from a short period of rest in bed.

General Paralysis.—The treatment by rest in bed has been tried on general paralytics by Dr. Joffroy

(1897). In Germany it has been suggested to keep the patient in bed for at least ten weeks at the commencement of the disease, in order to attenuate the initial symptoms. This treatment, it is urged, also exerts a favourable influence on the frequency of apoplectic attacks or convulsions (Rochrich). Rest in bed is especially indicated in cases of general paralysis, when, after a congestive attack, the patient shows signs of mental confusion. We have then to do with attacks of hallucinations, with automatic excitement, often very intense, analogous to post-convulsive epileptic delirium.

The treatment is therefore justified not only by psychical troubles, but also by the somatic phenomena.

Idiocy, Dementia.—Lastly, idiocy, cretinism, and dementia of every description, and even the morally insane, may conceivably derive benefit from the treatment in the event of a passing fit of excitement, to which they are so prone. Further research alone can establish the actual value of the method as a treatment in these cases, which, so far as we are aware, have not been methodically dealt with in this way.

We have now concluded the list of special indications for the treatment in the principal forms of psychoses. We trust we have justified our inaugural statement, that all acute conditions, whether of classical type or merely incidents in the course of chronic diseases, impose treatment by rest in bed.

Rest in bed alone can ensure to these patients that rest which the brain and the organism as a whole require; it is easy of application, its results in respect of the most troublesome symptoms of mental disease are indisputable, it obviates the physical and psychical complications which often impede recovery, and it enables us to dispense with prolonged isolation in a cell.

So thoroughly convinced are we of the advantages of this therapeutical method, that we do not hesitate to assert that it will rank with the suppression of restraint (*no restraint*), the open-door and the colonisation methods, as one of the most valuable acquisitions of modern psychiatry, and this method involves as a corollary a radical rearrangement of our superannuated system of dealing with the insane, a system which will henceforth stand condemned. The general application of the method will, of necessity, do away with our prison asylums, where therapeutical requirements count for so little, and will replace them by hospitals for the treatment of acute cases, by agricultural colonies for convalescents, intermittent and chronic cases. The treatment raises the lunatic to the dignity of a patient, a measure called for close upon a century ago by Pinel. The bed treatment alone will effectually complete the change, we shall no longer be satisfied with shutting up the insane, they will be treated, and we shall be enabled to return to their families and friends, a good number of unfortunate beings, who have hitherto been condemned by the imperfect method of treatment at our disposal to remain uncured.

SULPHUROUS ACID AS A REMEDY IN SKIN DISEASES.

By TOM ROBINSON, M.D.,
Physician to the Western Skin Hospital.

MODERN microscopical and bacteriological investigations have so strongly confirmed the fact that many of the skin eruptions are attributable to the invasion of the skin by micro-organisms that it has become the practice to attack such cutaneous manifestations by extreme remedies, remedies strong enough to kill the bacteria. The Germans have

been in advance of us for many years in their successful treatment of skin diseases. But Unna must be awarded the apple because he has possessed the art of combining remedies with a firm grip of physiology and pathology. It would be idle to allude to the many remedies which are advocated and used by us all, and it may be thought pedantic to say much about another one. The only excuse is that in sulphurous acid we possess a remedy which will not stain the skin, which will penetrate the epidermis, and which will certainly destroy most, if not all, of the *flora* which attack the skin, nails, or hair. The first group of cases which yield rapidly to its action are those which are connected with a faulty secretion of the sebaceous glands. The two varieties met with on the scalp, *Seborrhœa sicca*, and *Seborrhœa oleosa*, are the forerunners of alopecia, and have called for more commercial attention than any other skin affection. These will recover completely if the patient is directed to scrub the entire scalp once every twenty-four hours with recent sulphurous acid, and to wash the same once a week with common yellow soap. The varied varieties of seborrhœa met with on the face or trunk, will also yield to the same treatment. In cases of acne in which suppuration has taken place, the acid may be swabbed on the skin twice a day without dilution. In the ringworm group sulphurous acid, if persistently applied, will give as good results as any of the other germicides which are in common use. Its action in alopecia areata is excellent. In the ringworm of the scalp met with in children the affected areas should be washed with soft soap every day, afterwards swabbed at frequent intervals with the undiluted acid. The eruptions which occur between the scrotum and the thigh or wherever two folds of skin rub each other as in fat women under the breasts, armpits, and lower parts of the abdomen. These will yield to sulphurous acid if used diluted with spirit and water, equal parts of each and after its daily use a dusting powder, such as recommended by Dr. Walsh, and composed of two ounces of powdered starch and two drachms of boric acid and calamine powder. The object in writing these few remarks has been to call attention to a remedy which has not, I think, been sufficiently used in practice. There is only one word of warning necessary, it is that in ordering sulphurous acid let it be distinctly stated that the acid must be recent, otherwise it may act as an escharotic in consequence of the change of the acid from H_2SO_3 to H_2SO_4 , or in other words from sulphurous to sulphuric acid.

Clinical Records.

JESSOP HOSPITAL FOR WOMEN, SHEFFIELD.

Sub-peritoneal Fibroid in Douglas's Pouch—Operation.

Under the Care of JOHN W. MARTIN, M.D.,
Honorary Medical Officer to the Hospital.

L—O—, æt. 36, married, no children; admitted into the hospital September 16th, 1899. Quite regular as to her menstrual periods, the last commencing just after admission. About twelve months before admission she commenced to notice a sense of distension, especially towards the end of the day when tired from work. Inspection and palpation of the abdomen detected nothing. Per vaginam, the cervix was felt small and conical, and the sound was not easily introduced. When it did pass, it entered $2\frac{1}{2}$ inches and to the right. Douglas's pouch was occupied by what seemed to be a large hard tumour which could be well mapped out by the bimanual examination. The body of the uterus felt distinct from it, lying up along the right side of the

tumour. Movement of the tumour imparted a certain amount of movement to the sound in the uterus. A section was decided upon; the operation was done on October 18th. The tumour was found to be a sub-peritoneal fibroid, springing low down from the back of the uterus in Douglas's pouch. Its size was that of a good sized closed fist; its pedicle was about one-and-a-half to two inches in breadth. The operation was carried out in the usual way. The tumour was brought well out into the abdominal wound; fortunately there were no adhesions of importance to deal with; the peritoneal covering was incised before and behind, and reflected, the mass peeling off pretty easily. Hæmorrhage was arrested by ligature, some little difficulty being experienced in securing the largest vessel owing to retraction among the uterine tissues. Douglas's pouch was carefully washed out. The edges of the peritoneum were brought together by interrupted sutures. The abdominal wound was closed by five sutures. The patient did well, and was discharged on Saturday, November 18th, 1899.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, NOVEMBER 24TH, 1899.

SIR R. DOUGLAS POWELL, Bt., President, in the Chair.

A CASE OF SENILE TUBERCULOSIS.

MR. HOWARD MARSH read notes of a case of tuberculosis in an old lady, an example of the "senile scrofula" of Sir James Paget. In June, 1894, a lady, æt. 71, complained of swelling and pain in left ankle with dusky-red œdematous skin over it. In the following October it suppurated, when the joint was opened and drained. The pus, however, burrowed up the leg in the sheaths of the flexor tendons, with muscular wasting and general loss of strength. Amputation through the lower third of the leg was performed in March, 1895. The wound slowly healed, and the patient recovered her general health. Twelve months later the patient developed periostitis of the left ulna, which ultimately suppurated, and was opened and cleared, a small sinus remaining for three months. Nine months later, the patient being then 73, similar changes occurred in the right ankle, and a further amputation became necessary in March, 1897, which healed in five weeks. In June, 1897, an abscess formed over the ulna in the site of the 1896 periostitis, which was opened and slowly healed. She remained well for eighteen months, when, at 75 years of age, her right knee began to give trouble. The disease progressed rapidly and she lost flesh. Amputation through the lower third of the thigh was done four months' later, and healed without suppuration in six weeks. The patient had had no further trouble since. The condition of all three joints was the same, the disease having evidently begun in the synovial membrane, leading to complete destruction of the ligaments and articular cartilages, the bones being ulcerated in some spots. The cavity was occupied by tawny-coloured and friable granular tissue and cheesy pus, while the neighbouring soft structures were infiltrated with pus. He observed that the older the patient the greater was the tendency towards progressive, and usually rapid, destruction of the joint, the resistance of the tissues to the tuberculous process being greatly diminished by age. Diagnosis was often difficult at first, the symptoms closely resembling those of osteo-arthritis. Within two or three months, if not earlier, however, the infiltration of the soft structures, &c., would assist the diagnosis. Suppuration was a marked feature of senile tuberculosis leading to extensive and rapid destruction of the joint structures.

THE PRESIDENT asked if there was any early history of tuberculosis in this case, and whether the structures had been examined for bacilli? In his experience tuberculosis in the aged chiefly affected the lungs, and he thought the tendency of the disease in these patients was to remain local so that the prognosis was more favourable than in younger subjects.

DR. PERCY KIDD concurred in the President's remarks as to the less virulence in elderly subjects, and referred to a case of his own in a patient over 70 who died of peritonitis in which he found a tuberculous ulcer of the ileum. He thought tuberculosis of the joints in old people must be rarer than tuberculosis of the lungs.

MR. RAYMOND JOHNSON asked what results the author had obtained in tuberculous disease of the joints by other operations, such as excision, in the aged. He thought the virulence of the process in the aged was greater than with the same lesions in the young. He asked what explanation could be offered of the remarkable difference in the virulence in carcinoma and tubercle, pointing out that in the former growth was slow in the aged, whereas tubercle spread with great rapidity. He asked how it was, if surgical tuberculosis was so serious in the old, owing to defect of resistance, that they were not more often affected by the disease.

DR. J. S. RICHARDS said that as Medical Superintendent of a Poor-law Infirmary he had seen a good many of these cases. He had abstracted 500 post-mortem examinations made in the institution during the last two years; there were 17 of patients over 70 who had died of acute tuberculosis, 4 of them having miliary tuberculosis; while between 60 and 70 there were 16, 3 of them having miliary tuberculosis. About 6·6 of the whole number of deaths examined post-mortem (about half the whole number) were thus tuberculous. He did not take such a despairing view of tuberculous disease of the joints and bones as the author, for they often got good results, the effect of rest and improved diet being immense.

MR. MARSH, in reply, said there was no early history of tuberculosis in patient or family. No bacilli had been isolated, but the anatomical evidence was quite clear. The President had once remarked to him that joint tuberculosis was rare in phthisical patients, and his own experience at the Hip Hospital was that children with tuberculous joint disease seldom had the lungs diseased. He remarked that the incidence of the disease appeared to be different at different periods of life. In illustration of the very destructive effects of the disease he referred to the case of a lady, æt. 56, with hip disease, which, in four or five months, ran on to complete destruction and the patient developed phthisis and died. He pointed out that such an operation as excision was hardly applicable to patients over seventy. He thought that the disease affected old people much more frequently than was generally believed.

MR. BARKER ON A CASE OF

EXCISION OF THE CÆCUM.

The case described is that of a disease rare in the pathological condition found on operating, and also in the operative treatment to which it was submitted. Carcinoma of the ileo-cæcal valve is shown to be a rare disease by reference to the Transactions of the Pathological Society, and of the Clinical Society. That it should have given rise to intestinal obstruction is shown to be also rare. The case was that of a man, æt. 29, who was admitted into University College Hospital under the care of Dr. Risien Russell, by whom it was placed in the hands of Mr. Barker for operation, all other measures for relief having failed. The man had had attacks of chronic obstruction for a considerable period, culminating in an acute attack. The usual symptoms were well marked, but the patient's condition was generally good. On opening the abdomen in the middle line the small intestine was found much distended and hypertrophied. This was opened and five pints of liquid fæces of an intensely fetid character were evacuated. It was then possible to introduce the hand, when a hard mass was discovered in the ileo-cæcal valve plainly obstructing the bowel. As it appeared dangerous to remove it at once owing to the presence of much liquid fæces, the ileum was anastomosed to the hepatic flexure of the colon by suture, and wound was closed. The patient made a steady recovery, only checked by some stitch abscesses. At the end of six weeks and three days after the first operation a long oblique incision was made over the cæcum, and the latter was excised with some of the

ascending colon and about six inches of the ileum above the valve. Both viscera were divided a few inches below the ileo-cæcal union. The wound was packed with antiseptic gauze and left partially open. Convalescence was good, but a small fecal fistula remained open for some weeks, and then closed. The growth was found to be a carcinoma of the ileo-cæcal valve with many polypoid excrescences projecting into the cæcum. The specimen was shown as well as microscopic sections. The patient was also present for examination. He is in excellent health, and has returned to work as a plumber. His bowels act well, and he has no signs of recurrence so far.

Dr. VOELCKER agreed that it was probably adenocarcinoma. He could recall at least three examples of ileo-cæcal cancer met with post-mortem, all being cases of adenocarcinoma.

Mr. HOWARD MARSH did not think that this affection of the cæcum was particularly rare, and referred to a specimen in their hospital museum. He approved of the method of operation, viz., in two stages, some cases not being strong enough to undergo the graver operation, and he mentioned two cases in which removal of the cæcum had been practised with good results. He himself preferred suture of the intestine, but admitted that there were many cases which could best be dealt with by Murphy's button.

Dr. NORMAN DALTON referred to a case of his own of what looked like undoubted cancer of the cæcum in which, as the lump appeared to be slightly movable, he advised operation, and Mr. Burghard successfully removed the cæcum two years ago, since which time the patient had remained quite well. He agreed that this position for cancer was not so very rare.

Mr. CHARTERS SYMONS showed a drawing of a case of malignant disease which had begun in the ileo-cæcal valve in a woman, æt. 50, in which he removed the cæcum with success. He mentioned two other cases in which he had operated, the patient being still living, and he had just lost a patient in whom he had attempted the whole operation for obstruction. He thought that when there was an obstruction the operation should be undertaken in two stages, though in other cases it might well be done at one sitting. He had united the colon to the small intestine by lateral anastomosis, removing the excluded parts at a second operation. He agreed that direct suture was better, as it gave a freer passage than the button. He remarked that in the early stage the growth in all three cases had first occurred as a small hard movable nodule almost under the skin, followed by symptoms of slight appendicitis with ulceration, which healed and formed again, making the cases very protracted.

Mr. J. HUTCHINSON, jun., said that he had looked out the statistics of resection of intestine for gangrenous hernia, which showed that whereas the proportion of recoveries with the button was 7 per cent., careful direct suture showed 40 per cent. He alluded to the extreme difficulty of diagnosis of malignant disease in this situation, and gave two illustrative cases. One was that of an elderly man with carcinoma of the cæcum and symptoms of obstruction. Having relieved this, he was about to remove what looked like a cancer of the cæcum, but was deterred by the matting of the surrounding tissues, yet that patient had since steadily improved. In the other case the lesion was in the sigmoid flexure, in a middle-aged woman with obstruction. After exploration, median and lumbar, he found what had the appearance of a malignant growth with much inflammatory thickening around, rendering removal impossible. That patient, however, forthwith improved, and had remained well two years since. Treves and others had pointed out the impossibility in some cases of distinguishing between inflammatory infiltration and cancer.

Mr. BARKER in reply, thought that as the large intestine was often the seat of malignant disease, it was curious that the valve should be so rarely involved, at any rate so far as recorded cases went. He referred to two cases of gangrenous hernia treated by suture which recovered, while two others treated with the button had died.

Dr. C. W. CHAPMAN read a paper on a case of

OBSTRUCTION OF THE INFERIOR VENA CAVA—PROBABLY SYPHILITIC.

The patient, who was present, had been shown at a Clinical Meeting of the Society last Session. The patient was a hair dresser, æt. 48, who was admitted into the National Hospital for Diseases of the Heart on October 4th, 1897. He then complained of palpitation, shortness of breath on exertion, a shooting pain in the head, and a sense of suffocation when he leant forward. There was a history of syphilis twenty years previously, for which he had had only a two months' treatment. There were no secondary symptoms. His next illness was influenza in 1892, which was followed by palpitation. About nine months' later he had a sudden but transient severe pain in the head followed by swelling of the face, which, however, soon disappeared; he also was subject to syncopal attacks. The superficial abdominal veins gradually became enlarged and varicose, and subsequently the veins of the right leg were similarly affected. The action of the heart was feeble, and the pulse was 54. A systolic murmur of a harsh character was heard at the sternal margin of the 4th left space, also a soft systolic murmur at the apex which was heard in the left axillary line. The second pulmonic sound was a little accentuated. Liver, but little enlarged, Urine normal. No tumour could be discovered in the abdomen. There was a hard swelling at the back of the neck the size of half a walnut. The case was diagnosed as obstruction of the inferior vena cava for syphilitic disease either from pressure of a gumma or from thrombosis. Under specific treatment the swelling diminished, the symptoms relieved, and the health improved, though the condition of the external veins was unaltered. After referring to the more usual causes of obstruction of the inferior vena cava, Dr. Chapman quoted from Mr. Hutchinson's contribution on "Visceral Syphilis," where the author expresses his belief in the existence of a syphilitic phlebitis. He also drew attention to the article on syphilitic phlebitis in the *Archives Générales de Médecine* for 1894, where the author refers to two cases of phlebitis associated with gummatous tumours. Mr. Battle's paper, 18th volume of St. Thomas's Hospital Reports, was also quoted as bearing on the subject.

Mr. J. HUTCHINSON, jun., asked how it was that there was no marked enlargement of the veins of the lower limbs and no varicocele inasmuch as the vena cava was undoubtedly obstructed. He mentioned the case of a lad of 16 with varicocele in both sides, the veins of the legs being extremely dilated and tortuous, in whom there was obvious obstruction of the lower vena cava. There was no ascites, but the liver and spleen were decidedly enlarged, with other evidences of congenital syphilis. This patient improved under KI. and Hg., though the veins did not regain their normal size. The obstruction was undoubtedly due to a gumma at the posterior surface of the liver, but he pointed out that with syphilitic disease of the liver and spleen there might be tertiary disease of the lymphatic glands lying behind the inferior vena cava. It was well known that gummatous disease of the lymphatic glands had a greater tendency to infiltrate neighbouring vessels than tuberculous disease. He referred to a case of gumma in the cervical lymphatic glands pressing upon the carotid and infiltrating the hypoglossal nerve, also a case of obstruction of the superior vena cava which was obliterated by a large gummatous mass which had apparently started in the mediastinal glands. There was a specimen in the College of Surgeons' Museum of obstruction of the superior vena cava. In this case, as the subject had angular curvature of the spine, it was of course open to the suspicion of tubercle, but Mr. Targett, who had carefully examined the specimen, decided that it was syphilitic. Dr. Barlow had given him notes of a case in which the veins of the right arm and chest were enormously distended in which recovery had followed vigorous antisyphilitic treatment.

Dr. CHAPMAN, in reply, remarked that the veins of the legs were also greatly enlarged in his patient.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD THURSDAY, NOVEMBER 16TH, 1899.

Dr. W. J. Gow, Vice-President, in the Chair.

SOME INTERESTING CASES OF FIBROID TUMOURS OF THE UTERUS.

DR. A. H. N. LEWERS read a paper on nine cases of fibroid tumours of the uterus. The cases illustrated some of the principal varieties of uterine fibroids, and showed some of the chief methods of treating them in use at the present time. In Case 1 the chief point of interest was the remarkable diminution in the size of the fibroid tumour following removal of the uterine appendages. On one side the ovary formed a suppurating ovarian cyst the size of a cocoa nut. Cases 2, 3, and 9 were typical examples of large uterine fibroids, successfully removed by abdominal hysterectomy, with intra-peritoneal treatment of the stump. In Case 3 a point of interest was, that in one place the fibroid had undergone cystic change, and the cavity so formed contained pus. Case 4 was an example of pregnancy complicated with a large subperitoneal fibroid, in which expectant treatment was adopted with a satisfactory result, the patient being delivered naturally at term, without any complication, either during the labour or afterwards. The patient was seen some two or three months afterwards, when the subperitoneal fibroid could still be easily felt on abdominal palpation alone. Cases 5 and 6 were examples of removal of fibroids, partly submucous and partly interstitial, from the cavity of the body of the uterus after dilatation of the cervix by enucleation and "morcellation." Case 8 was one of large sub-peritoneal fibroid removed by myomectomy with intra-peritoneal treatment of the pedicle, and in this case the body of the uterus was not removed. Case 7 was, on account of its rarity, perhaps the most interesting of the whole series. It was a case where an interstitial fibroid of the posterior wall of the uterus sloughed *en masse* and was discharged through an opening formed in the posterior lip of the cervix. When first seen (May 30th, 1899) the case appeared an ordinary one of uterine fibroids, the tumour reaching nearly to the umbilicus. The vaginal cervix at that time was not encroached upon by the fibroids at all, but on July 20th, 1899, the upper part of the vagina was found occupied by a large foetid friable mass. Careful examination under anaesthesia showed that the os uteri lay in front of it, and that this mass was coming through an opening formed in the posterior lip of the cervix. The patient was feverish and extremely ill. All that was done was to remove the foetid mass with the fingers as completely as possible, much as a decomposing retained placenta would be removed, except that in the present case the decomposing mass (the fragments of which weighed 2½ lbs. 8 ozs.) was situated in the substance of the posterior uterine wall, and not in the cavity of the uterus. The patient continued to suffer from septic fever even after the sloughing fibroid had been removed as completely as possible, and finally died from it some three months later. The specimens corresponding to several of the cases were shown.

The CHAIRMAN referred to the importance of the subject under discussion because, since the mortality of hysterectomy had so greatly diminished, the indications for operative treatment had considerably altered. He criticised the employment of drainage after abdominal hysterectomy, and considered that it was seldom necessary.

Mr. ALBAN DORAN dwelt on different surgical methods for the treatment of uterine fibroids which he had seen introduced, practised, supported by plausible arguments, and yet often discarded. There was still great room for improvement; the removal of small fibroids which caused no symptoms was bad surgery, though it might be brilliant operating. Altogether retro-peritoneal hysterectomy was preferable to the more conservative myomectomy and to the more radical panhysterectomy. Too great stress was now laid upon the supposed advan-

tages of leaving the ovaries, just as too much importance was attached twenty years ago to their complete removal. The surgeon must remember that leaving the ovary might mean shutting up in the abdomen a portion of a diseased tube with its mucous membrane exposed. Abel and Zweifel had shown on clinical evidence that when the ovaries were left behind they nearly always atrophied so that the menopause occurred within three years of the hysterectomy. Zweifel believed that when this atrophy did not occur it signified that a portion of the body of the uterus was left in the stump; hence he now made large flaps consisting of more than the tissue of the cervix. We had yet much to learn, but in the meantime we could remember that an artificial menopause was seldom very formidable.

Dr. W. H. TATE agreed with the remarks of the Chairman with regard to drainage in cases of abdominal hysterectomy for fibroids. He considered that drainage was rarely necessary where the broad ligaments and uterine arteries had been securely ligatured, and the stump carefully sutured. Referring to Case 7 in the paper, he wished to ask Dr. Lewers whether he did not think removal of the whole uterus might not have given the patient a chance of life, seeing that partial removal of the sloughing tumour per vaginam had failed to relieve her. Dr. Tate had assisted Dr. Cullingworth in a case in which a large sloughing fibroid tumour occupied the vagina, and an attempt had been made to remove it. It was found impossible to remove the whole tumour—the portion left behind sloughed, and the patient's condition became extremely grave. Three days after the first operation Dr. Cullingworth decided to perform abdominal hysterectomy, and the patient made an excellent recovery. Mr. Doran had referred to the greater mortality in the cases of operation on large fibroid tumours compared with small. He (Dr. Tate) did not agree that this was the case, as it frequently happened that a large fibroid tumour was much more easily and safely removed than a small one. Bearing on the operation of oöphrectomy for fibroids, he thought it was important to consider the symptoms before deciding on this means of treatment. Even when the size of the tumour did not contraindicate the operation, the symptom of severe pain over the tumour suggested some degenerative or necrotic change in it, and it was doubtful whether, under these circumstances, removal of the ovaries would be followed by the desired result.

Dr. BOXALL drew attention to the difference in fibroids, to variation in their position and mode of growth, and of the symptoms to which they gave rise; differences which affected materially the question of operative interference and the choice of the most suitable operation in individual cases. He instanced several cases which presented unusual features and, in particular, directed attention to the necessity of taking measures to prevent large abdominal fibroids from sinking into and becoming impacted in the pelvis during the shrinkage which usually takes place after the menopause.

Dr. LEWERS replied.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, NOVEMBER 9TH, 1899.

(Report continued from our last issue.)

The President, Dr. MACNAUGHTON-JONES, in the Chair.

Dr. R. H. HODGSON brought forward a case of
TUBERCULOUS PERITONITIS.

Full notes of this interesting case will be found on page 552. In the discussion that followed,

Mr. CHARLES RYALL remarked that the reason of the disappearance of the tuberculous conditions in these cases was not known; it might be brought about by means of the portal congestion which followed abdominal section. This view had been carried out in practice in the treatment of tuberculosis of the knee-joint, by compression of the

vessels of the thigh. He did not think that any antiseptic was of much good in the peritoneum, since to kill the bacilli it must also kill the peritoneal cells. The best peritoneal antiseptic was normal salt solution; the next best was plain water.

Dr. C. H. F. ROUTH said that the opening of the abdomen was enough in many cases of tuberculosis to cure the disease. He would not say that they should be satisfied with opening the abdomen; but when nothing more could be done, they might still hope for good results. In the same way some cases of cancer were benefited. It was on this principle that tuberculosis was cured by the open-air treatment and by oxygen. It seemed to him a very strange thing to leave a drachm of carbolic acid in the abdomen.

Dr. INGLIS PARSONS thought that they could accept Dr. Hodgson's diagnosis in this case. The use of carbolic acid was interesting, and it did not appear to him likely to be followed by toxic effects; for in all cases in which there had been peritonitis they found that after abdominal section there was very little reaction on the part of the peritoneum. With regard to the effect on a tuberculous peritoneum of opening the abdomen, it was interesting to note that Howard Kelly mentioned several cases in which a patient was operated on for tuberculous peritonitis and died some time afterwards from some other cause; the tubercles were still to be found in the peritoneum, but isolated and encysted; the tubercle bacilli also were there, but unable to do any harm.

Mr. BOWREMAN JESSETT believed that Dr. Inglis Parsons' explanation of peritoneal immunity was the correct one, otherwise the patient would probably have died, with a drachm of carbolic in her peritoneum. For himself, he hardly dared to use carbolic for his instruments in abdominal operations.

The PRESIDENT said that he could look back to many cases in which he had got quite unexpected credit for cures after opening the abdomen for tuberculosis. The reason for the improvement or the cure was not yet quite satisfactorily explained. Dr. Hodgson's treatment with carbolic was rather heroic; but they should remember that the peritoneum, of children especially, in cases where there had been tuberculous peritonitis, did really become case-hardened as Dr. Inglis Parsons had said; and under those circumstances a drachm or two of carbolic acid did not perhaps much matter. A similar induration of the peritoneum was found in the case of diseased appendages.

Dr. HODGSON briefly replied.

Dr. JAMES OLIVER read a paper on the
PHYSICO-CHEMICAL CHANGES CONCERNED IN THE PRODUCTION OF VERSION OF THE UTERUS.

This paper will be found in another column. The discussion thereon was adjourned to the next meeting.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, NOVEMBER 3RD, 1899.

Dr. E. H. BENNETT, President of the Academy, in the Chair.

Dr. ARTHUR H. BENSON and Dr. H. C. EARL exhibited a series of Pathological Eyes, half globes, mounted in formalin, and Microscopic Sections. (a) They showed a specimen of glioma from a child, *æt.* four months. It was now seven months since the operation, and so far no recurrence had taken place. (b) The second specimen, sarcoma of choroid, was from a boy, *æt.* 3. On admission a fungating mass, the size of a duck's egg, was protruding from the right orbit. The contents of the orbit were removed, but it was found that the orbit back to the posterior foramen was completely filled with the growth, and the optic nerve was so disintegrated that no trace of it was visible to the naked eye. As the growth could not be entirely removed the prognosis was bad, and recurrence did actually take place a month after the child's return home. (c) The third specimen, epithelioma of cornea and

conjunctiva, was taken from a man, *æt.* 69. The whole cornea and part of the ocular conjunctiva were covered by the growth, which was so extensive, and seemed to penetrate so deeply into the sub-jacent tissue that it could not with safety be excised, enucleation giving the man his only chance. The tumour was unpigmented, flat, and sessile, with a very broad base, and had ulcerated. (d) Bony degeneration of choroid in a woman, *æt.* 50, who had had a diabetic cataract removed from one eye in 1898. It was irritable and painful to the touch, and, as it was believed to be the source of irritation in consequence of possessing a bony choroid, it was removed. The choroid was found converted in its whole extent into a layer of true bone. The lens was calcified but not ossified. (e) Intra-ocular hæmorrhage. Patient, *æt.* 45, gave history of cataract of right eye of four years' duration. During the last three months the pain in the eye had been very severe, and one month ago a large hæmorrhage occurred, which filled the anterior chamber, and the pain became constant and intolerable. The tension was about — 1, and the globe had the appearance of a shrinking one. Enucleation was performed. No cause for the hæmorrhage, which probably came from the iris, was found. (f) Collapsed globe, after cataract removal, in a woman on whose left eye a combined extraction of an opaque lens was performed. An asthenic suppurative cyclitis resulted, the globe shrank, and the vision was lost in the eye. Seven and a half months after the globe was collapsed, and the right eye had a condition very suggestive of sympathetic ophthalmitis — serous iritis keratitis punctata, pupil fixed, tension normal, and slight circumcorneal vascularity. The lens was opaque, and no illumination of the fundus could be obtained. There was no pain. As the shrunken left globe was believed to be the cause of the trouble in the right eye enucleation was performed. Four days later the patient became delirious. She continued in a low state, and thirteen days after operation refused food altogether, and the bowels acted involuntarily. No organic lesion could be found, and she died sixteen days after operation.

Mr. HENRY GRAY CROLY exhibited specimens of (1) fracture of the base of the skull; (2) sarcoma of testis. The fracture of the base of the skull was the most perfect he had ever seen. It extended through the petrous bone, body of sphenoid, and ethmoid. The man was found on the road in a pool of blood, and was carried to hospital in a collapsed state. There was great hæmorrhage from both ears. He recovered consciousness sufficiently to say that he felt himself better. He lived for three days. There was no lesion of the brain, and no hæmorrhage into the brain. There was no fracture of the vault of the skull.

The PRESIDENT recalled a case of fracture of the skull in which the occipital and frontal regions could be moved on each other. The man recovered completely.

Mr. CROLY, in reply, thought the case mentioned by the President was one of fracture of the vault of the skull. Men recover occasionally from fracture of the base of the skull. In this case the remarkable fact was that the man lived so long.

Dr. KNOTT showed some specimens of fractured humeri. In connection with one showing fracture of the lower end of the bone, he drew attention to the fact that the epiphyseal line of the lower articular surface of the humerus does not involve the condyles.

The PRESIDENT concurred in the diagnosis of one of the specimens as a fracture passing obliquely through the elbow-joint, as it had none of the features of an epiphysary displacement.

Mr. CROLY, referring to one of the specimens, pointed out a fact which he thought a great many did not know, and which Robert Smith had drawn particular attention to—namely, that epiphysary fracture of the upper end of the humerus included the tuberosities. He himself, in teaching fractures of the upper end of the humerus impresses on his pupils that there were two fractures of the surgical neck, one being epiphysary below the tuberosities, one lower down in the surgical neck. The line of fracture through the anatomical neck is above the tuberosities. Speaking of the specimen D Bennett had drawn attention to, he would certainly say

it was not an epiphysary fracture, since the condyles here were carried forwards instead of backwards, which they knew was distinctive of epiphysary disjunction.

Dr. Knorr, in reply, said that the epiphysary line at the upper end of the humerus was always exactly horizontal. In addition to the observation Mr. Croly had made that from the action of the triceps it would be almost necessary that there should be a backward displacement in epiphysary disjunction of the lower end of the humerus, there was also the point that his specimen involved the external condyle, which it would not do if it were an epiphysary disjunction, as the external condyle did not belong to the epiphyses, but to the shaft.

The Section then adjourned.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, November 26th, 1899.

WOUND OF THE BLADDER.

At the last meeting of the Société de Chirurgie, a member related the case of a man who was wounded in the bladder through a stab of the knife in the gluteal region. The blade, after having traversed the sciatic notch passed into the bladder, which was filled with blood. Vomiting, accompanied with considerable distension of the abdomen, decided the speaker to perform laparotomy; the peritoneum was untouched, but beneath it existed a vast effusion of blood. A probe introduced through the external wound showed that the wound in the bladder was behind; not being able to suture it, the operator closed the abdomen and turned his attention to the gluteal wound where he found the artery of the same name cut. He passed a ligature on it without difficulty, and the man recovered.

INTERCRANIAL ABSCESS.

M. Schwartz spoke on a case of intercranial abscess in a girl of eleven years and cured by operation. The patient suffered after an attack of scarlatina from supuration of the middle ear, and one day was suddenly seized with cerebral symptoms of extreme gravity, and the mastoid process became painful to pressure. The apophysis was accordingly incised, and the cells found to be filled with pus, but the operator was convinced that there was a collection of pus inside the skull, trephined the floor between the antrum and the middle fossa from the base of the brain through which a considerable amount of pus was extracted. The patient recovered rapidly.

CHRONIC ECZEMA.

A confrere asserts that he obtains the radical cure of chronic eczema where it occurs in isolated patches on the upper extremities and so rebellious to the ordinary method of treatment, as follows: after having washed thoroughly with soap and water the part and dried it, he rubs in vigorously a 50 per cent. solution of caustic potash by means of a plug of cotton tied to a rod; he then washes the spot freely with water, and, finally, paints it over with a 50 per cent. solution of nitrate of silver, and envelops the whole in aseptic cotton. This dressing is left in place until the cicatrix has formed beneath the slough, or from one to two weeks. The itching ceases immediately after the application of the caustics. Out of thirty cases thus treated, only one required the operation a second time.

HERPES ZOSTER.

Every one knows what a painful affection herpes

zoster is, and how numerous are the local applications prescribed as affording the best relief. It being due to inflammation of the nerve supply of the region, quinine is the natural internal remedy, but externally absorbent powders and ointments have been plentifully advised with more or less success. Dr. Bleuler says an ointment composed of equal parts of lanoline and vaseline with 1 per cent. of cocaine provokes almost immediately regression of the eruption, causing it to disappear entirely in a few days.

A TRAVELLING NEEDLE.

A girl of seventeen presented herself to a doctor in a locality well known to me, complaining of pain in the left breast of acute description. On being examined a small tumour was felt which on pressing gave the sensation of a foreign body with a sharp point. The doctor recognised a needle or a pin, and cutting down on it had the satisfaction of withdrawing a fine needle. Questioned as to how it got there, the girl said that she remembered having swallowed a few months previously a needle by accident, but as it gave her no trouble she had forgotten all about it.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, November 25th, 1899.

At the Medical Society, Hr. L. Landau showed

TWO EXTIRPATED TUMOURS.

One was a multiple fibroid removed by laparotomy. The whole uterus, collum included, was removed. During the operation it was seen that the cervix was the seat of a carcinoma, which had not been and could not have been recognised before. The hæmorrhage and emaciation did not point to it, as they were caused by the fibroma. This carcinoma must have spread further if supravaginal amputation had been performed, and then it would have been thought to have developed in the stump after operation. The case therefore showed in a striking manner, like the seven earlier cases in which operation had to be performed on account of development of carcinoma in the stump, that supravaginal operation should be dropped and that total extirpation was preferable. The second was a tumour removed from a lady of 50, who two years ago had a tumour the size of a child's head, and which grew rapidly. The emaciated lady presented the symptoms of a simple ovarian sarcoma. Whilst carcinoma was generally two-sided sarcoma was usually unilateral and the prognosis much more favourable, so that definite recoveries had been observed in bilateral cases when the sarcoma of one side only had been removed.

Hr. James Israel showed a

MALIGNANT TUMOUR

from the inner inguinal ring, springing from an undescended testicle. The patient, at. 30, had suffered a year before from an attack of pain in the right inguinal region, and noticed a swelling in the loins. The speaker found a prominence of the lower abdomen; taking in both halves, stronger in the right than in the left, and on that side the testicle was absent from the scrotum, and in place of it a sausage-shaped hydrocele. The margin of the tumour was at the level of the umbilicus upwards and below Poupart's ligament to the

left, four fingerbreadths beyond the mid line, the right side taking in all that part of the lower abdomen. The operation was difficult. The tumour was retro-peritoneal, the lower surface in close connection with the iliac vessels. Below there was contact with the bladder, above the large intestine was displaced upwards, and attached to the neighbouring parts, on the left the tumour touched the sigmoid flexure. The extirpation was so difficult from the fact that simple enucleation was not sufficient, but it had to be carefully separated from its attachments. Another great difficulty lay in sufficiently protecting the large remaining cavity, the surface of which was raw and not covered with peritoneum from infection. The raw surface was united to the margin of the anterior parietal peritoneum, so that the intestine was completely protected, and could not come into contact with the wound. The tumour covered the tunica vaginalis communis over the whole extent, and showed itself microscopically to be an alveolar sarcoma, that on hasty observation might easily be mistaken for a carcinoma.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, November 25th, 1899.

TABIC ARTHROPATHIA.

SCHNABEL exhibited a young man, æt. 33, at the last meeting of the "Gesellschaft der Aerzte" with tabic arthropathia of both ankle-joints.

In 1890 he suffered from an ulcer on the frenulum preputii accompanied with other specific phenomena. Three years later he suffered from severe lancinating pain in both legs. Four years ago for the first time a swelling commenced to form on the left foot followed in a short time by a similar enlargement on the right, but with no special history of severe pain. Since the commencement of the present year the position of the feet has rapidly changed, and they are now twisted outward at the ankles, having every appearance of talipes varus, more particularly the left. The bony swelling of the lower end of the tibia and os calcis is the cause of the displacement.

The tabic symptoms are to be found in the lancinating pains, the Westphalia phenomena, and the minimum of pain in its production. Against this, however, there is no ataxia, nor pupillary symptoms. Syringomyelia may be excluded, as there is nothing present to support the hypothesis.

LUPUS AND RÖNTGEN RAYS.

Thurnwald brought forward a young man whom he had treated with Röntgen rays for lupus on the face with the best result. It had originally been treated in the orthodox surgical manner without effect; it was scraped and painted with an 80 per cent. of lactic acid with no benefit. After a short term of treatment with the rays, the disease has quite disappeared.

POLIOMYELITIS IN THE ADULT.

At the "Medical Club" Redlich showed a patient, æt. 49, who earlier in life had been in charge of a railway station, but recently had been a tramway conductor. About a year ago he had a sharp pricking pain in the right foot, which soon passed off but left a weakness behind, this has gradually increased and extended up the leg till February when he found he could no longer perform his usual duty

In July the same weakness commenced in the right leg, gradually increasing with the same wasting of the muscles. Patient had always been healthy up to the pain in foot; no evidence of syphilis; a non-Potus; and no trace of injury to be discovered.

His present appearance when standing has a waving character, not ataxic, but rather due to the weakness of the muscles. The atrophy since July has been very marked, with fibrillary contractions in the muscles of the thigh. He still has a little power in the lower and upper part of the left leg, but the foot is quite paralysed. The patellar reflex is active; the Achilles tendon reflex in right absent, in left present; sensibility intact; degeneration extensive; while there is no bowel or bladder disturbance.

The first thought in this case would be alcoholic polyneuritis, but the usual pain and paræsthesia, as well as the historical "Potus," are absent. Again, toxic agents such as lead and diabetes, might produce similar effects, both of these, however, were absent. It was finally left to distinguish between muscular atrophy and chronic poliomyelitis. Against the first is the localisation, the comparatively rapid course and the complete atrophy of the muscle; while in muscular atrophy, the degeneration would be in bundles and the course would be slow and gradual.

Although the symptomatic diagnosis may be thus easily differentiated the pathological anatomy cannot be so readily defined, as both are due to a degeneration of the ganglionic cells in the anterior horns of the cord.

RAYNAUD'S DISEASE.

Neurath exhibited a five-year old boy who has suffered for the last two years from attacks of cyanosis in the distal parts of the body, such as the fingers, ears, and point of the nose, which is accompanied with swelling and blisters. Neurath stated that he had observed these attacks personally, and on many occasions they had lasted for days at a time. He is of opinion that they have some connection with the effects of cold on the system, and believes that this case has now reached the second stage of this complex disease. The third stage usually ends in gangrene and death. The prognosis in such cases is very uncertain, as no drug has hitherto been effectual in warding off the danger of subsequent gangrene. Iron and arsenic seem to be the principal agents held in respect, but their action has seldom been successful.

South Africa.

[FROM OUR OWN CORRESPONDENT.]

THE TRANSVAAL WAR.

Our Special Correspondent at Cape Town sends us the following interesting summary of events. His letter is dated November 12th, and states that everything has been put aside in medical circles in order to provide in every possible way for the care and comfort of the sick and wounded:—

The only general hospital that had been fixed upon at the time of writing was that at Wynberg, a suburb of Cape Town, where the whole of the barracks have been utilised for hospital purposes, affording accommodation to about 600 men. The hospital is excellently fitted up with every modern appliance. Colonel Anthonez

is in command, with Colonel Grier as secretary and registrar.

As at present arranged, all the sick and wounded from Natal are to be brought there, a very wise determination, as the coast climate of the Garden Colony is most depressing at this time of the year. The Wynberg Hospital is in a most healthy situation, well up the side of Table Mountain, and the climate in the Cape Peninsula is, even in the midst of summer, never oppressively hot or damp. A batch of sick and wounded have already arrived, and are doing well. The 'Spartan,' which has been entirely reconverted for hospital ship purposes, has just gone to Natal for another consignment.

It is possible that one or two more General Hospitals may be established, perhaps at East London and Port Elizabeth, but that depends upon the General's line of advance. Station Hospitals will, of course, be fixed at various points up country.

Surgeon-General Wilson has taken over the chief command from Colonel Supple. Two well-equipped ambulance trains have been constructed locally, and will be used for conveying sick and wounded down the line. Detachments of the St. John's Ambulance Association, Cape Town Centre, will take charge of these trains from De Aar downwards. These detachments are undergoing drill in train work daily at the Station Hospital. The same Association will take charge of sick and wounded from the Cape Town Docks to Wynberg.

Dr. Hoffman, Member of the Assembly for the Paarl, a very active Bond politician, has joined the Free State forces with an ambulance party of ten, all laymen, one, however, being an ex-medical student. At the last moment, he applied to the local St. John's Centre for permission to go under its authority. After some consideration due to the fear that the mission might be in some way a political one, the permission was granted on the distinct understanding that the party was to be absolutely bound by the Geneva rules, and by the regulations of the St. John's Association.

Abundance of civilian help, both professional and nursing, is being offered to the military authorities, but owing to the large number of medical officers, civil surgeons, and nurses sent out from England, it has not been made use of as yet.

In Natal, however, civilian aid is well in evidence, likewise at the beleaguered towns of Mafeking and Kimberley.

Dr. Buntine, surgeon to one of the Natal Volunteer Corps, greatly distinguished himself at Elands Laagte, and, it is said, is to be recommended for the Victoria Cross.

The Operating Theatres.

GREAT NORTHERN HOSPITAL.

OPERATION FOR SO-CALLED FIBRO-LIPOMA OF NOSE.—Mr. PETTON BEALE operated on a man, *æt.* 45, whom he saw at the request of Dr. Whitfield. The patient had been attending Dr. Whitfield's dermatological clinic suffering from large pendulous deformity of the nose, commonly described as fibro-lipoma. The man being very anxious to have the disfigurement remedied, Dr. Whitfield had advised him to become an in-patient, and had suggested to Mr. Beale that he should shave off the pendulous masses. The patient was

anæsthetised and the nose cleaned as far as possible. The pendulous masses were then shaved off with a sharp scalpel until the nose was reduced in size and appearance to that of the normal organ. Some of the pieces removed were three-quarters of an inch in thickness; the bleeding was, of course, very profuse, but no vessels which could be clamped were visible. The nose was dressed with layers of cyanide dressing (on the removal of this the next day, a layer of protective and gauze was substituted, the nose was dressed daily, and by the fifth day the raw granulating surface was found to be studded all over with islands of epithelium, these gradually coalesced, and on the tenth day the nose was almost entirely covered with new skin). Mr. Beale remarked that these so-called fibro-lipomata of the nose were in reality large masses of hypertrophied sebaceous glands with some fibrous tissue between them. On microscopical sections this tumour was found to consist almost wholly of sebaceous glands and large circular spaces lined with apparently normal stratified epithelium. This condition was present even in the very deepest parts of the growth. It was thus evident that the only treatment required was free removal, subsequent skin-grafting by Thiersch's method being in no way necessary. During the process of shaving off the tumour he said it was advisable to feel for the cartilage with the finger, so that a small amount of tissue might be left covering the cartilage.

SUPRA-PUBIC CYSTOTOMY FOR CALCULUS.—The same surgeon operated on a man, *æt.* 60, for vesical calculus. The point of interest in the case was the absence of symptoms of stone. The patient came to the hospital complaining of blood in the urine from which he said he had suffered on two occasions previously during the last year. The blood appeared in large quantities, and was persistent for a few hours only. The presence of the blood was not influenced by movement or exertion, but had appeared on each occasion after a night's rest. He was admitted as it was supposed he had a papilloma of the bladder. A sound was passed, and it only detected what appeared to be a large stone lying at the base of the bladder. This was removed by supra-pubic cystotomy, and was found to be triangular in shape with rounded edges, 2½ inches in its largest diameter, 1 inch thick, the greater part phosphatic in nature, but the centre composed of urates. Mr. Beale said it was a curious fact that the presence of blood was the only symptom of so large a stone; moreover the blood had only appeared three times and the surface of the stone was fairly smooth. He supposed that the stone had been partially encysted at the base of the bladder, and that the hæmorrhage occurred when for some reason or another the stone had slightly shifted its position. The interior of the bladder was thoroughly examined at the time of operation, and nothing but a slight roughness of the mucous membrane at its base could be detected.

ROYAL EAR HOSPITAL.

REMOVAL OF THE MEMBRANE, MALLEUS AND INCUS FOR CHRONIC NON-SUPPURATIVE MIDDLE-EAR DISEASE.—Mr. ARTHUR H. CHEATLE operated on a man, *æt.* 20, who for some years had suffered from gradually increasing deafness in both ears, and who once previously had had adenoids removed but with no good effect to his hearing. On examination of the ear it was seen that the membrane and malleus were retracted, and on applying

Siegle's exhausting speculum it was seen that they were closely adherent to the promontory, thus accounting for the non-improvement after the previous removal of the adenoids. Inflation through the Eustachian tube produced no improvement in hearing nor in the position of the membrane, but the tone conduction was good, and the patient desired everything possible to be done to improve his hearing for the purposes of his work, therefore it was decided to remove the membrane malleus and incus, and so to expose the head of the stapes to the direct influence of sound waves. The auricle and meatus having been thoroughly purified, especially the cartilaginous portion of the meatus, the patient was placed under chloroform, the ear again purified (the man being laid prone turned three-quarters to the right side under a good reflected light), an incision was carried round the periphery of the membrane with a sharp pointed knife, and the malleus freed from its adherence to the promontory. Delstanché's ring knife was then looped over the handle of the malleus, and passed upwards in order to divide the tendon of the tensor tympani; the malleus was then extracted by means of a strong pair of forceps as high up as possible, being first pulled downwards to free it from the attic and then outwards. The incus was then turned out of the attic into the lower middle ear by means of a Lake's incus curette, and removed with forceps. The middle ear was then gently mopped out and the canal plugged with double cyanide gauze wrung out with 1 in 40 carbolic solution, an outside dressing and bandage being applied to the auricle, which would remain *in situ* for a week. Mr. Cheate spoke of the great importance of antiseptic precautions, which did away with all risks they being as applicable to the auditory meatus as to any other part of the body; for the purification carbolic lotion 1-20 was especially useful as it penetrated greasy substances. The cartilaginous meatus, he said, required thorough scrubbing with a strong mixture, that is, 1-20 carbolic acid, in which is 1 in 500 part of perchloride of mercury; the 1 in 20 is instilled into the meatus for 15 or 20 minutes before the operation; no evil effects are produced by these strong solutions beyond slight desquamation. With regard to the prospects of improvement in hearing following the operation, it had been pointed out to the patient that no good results might be obtained. If when healing had occurred at the end of a fortnight or three weeks, no improvement was noticed, the effect of an artificial membrane placed on the head of the stapes would be tried, and if no improvement then occurred, it would be inferred that the stapes might be bound down by adhesions round its crura or at its base which would require subsequent dealing with. The importance of excluding any internal ear complication by means of the tuning fork was, he said, of the utmost importance, as any signs of internal ear impairment contra-indicated operation. He remarked that sometimes there is difficulty in removing the incus; in using any form of incus hook it was important to place it well into the cavity of the attic in its anterior part and to rotate it backwards and downwards on its own axis. Difficulty may be experienced too in finding the incus after it has been turned into the lower middle ear, on account of the bleeding obscuring the ossicle; syringing, he said, may remove it in such a contingency.

The patient subsequently had no pain, no temperature;

on removing the dressings in a week it was too early to judge of any improvement in the hearing. The important point was the absence of any sign of infection.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 29, 1899.

MEDICAL POLITICS AT NEWCASTLE-ON-TYNE.

THE meeting organised by the North of England Branch of the British Medical Association, which took place at Newcastle-on-Tyne on Wednesday last may be interpreted as a sign that the medical profession is awakening to the imperious necessity of co-ordinated action with the object of improving the status and safeguarding the privileges of medical practitioners, not only in regard to the public but also in respect of their domestic arrangements. The addresses of the three direct representatives show that although they envisage the question of reform from different standpoints they are all convinced of the urgency of taking concerted measures to remove, at any rate, the more salient abuses. Some of these, it may reasonably be supposed, may be overcome by steady pressure brought to bear on the governing bodies, but others, not the least important, will probably require legislative interference. Mr. Victor Horsley, with characteristic vigour, attacked the actual constitution of the General Medical Council, but he shifted the onus from the Council on to the shoulders of the "extraordinary series of little oligarchies" who appoint by far the greater number of the members of that Council. Without going so far as to allege that the councils of the various licensing bodies have "usurped" the right to speak and act as the representatives of their corporations, it is evident that in exercising that power they arrogate to themselves a position and influence out of all proportion

to their intrinsic importance, seeing that their alumni have, for the most part, no voice or influence in directing the course of events. Even if the functions of the Council were limited to regulating medical education the presence on that body of such a crushing preponderance of representatives of purely examining bodies would be objectionable because their interests do not favour a high standard of medical education but, on the contrary, entail the qualification of a maximum number of candidates. Of late years, however, the other functions of the Council have intruded themselves more and more on the attention of the profession, and under pressure of public opinion those functions tend more and more to occupy the time and energy of the Council, thanks especially to the vivifying influence of the direct representatives who, whatever may be asserted to the contrary, are indisputably more in touch with the aspirations and needs of the profession than their academic colleagues. From this point of view we share with Mr. Horsley the regret that "our unfortunate profession should be doubly governed by a series of small oligarchies who regard themselves as entirely irresponsible to the great body of practitioners, their colleagues in the profession to which they have the honour to belong." The alleged apathy of the general practitioner in voting for direct representatives, which is made use of as an argument for refusing to countenance any addition to their number, is very possibly attributable to the consciousness that the presence at the Council Board of a sprinkling of direct representatives cannot avail much against the interested opposition of a large majority of the delegates of corporations. Mr. Horsley is especially hard on the method of conducting the legal business of the Council, and it is generally admitted, even in the bosom of the Council, that there is plenty of margin for improvement in this direction. The time is past, we imagine, when senior members of the profession will dare to ascribe movements towards reform as the outcome of "an insignificant coterie of discontented men," for the questions now before us interest all who are engaged in general practice to a degree which they are only beginning to appreciate. Mr. George Brown was hardly less decided in his views as to what it behoves the profession to aim at, but his panacea seems to be that Will-o'-the-Wisp one-portal system which has several times been apparently on the eve of becoming law, but is still out in the cold. Much as has the one-portal system to recommend it, and anomalous as is the present multiplication and constitution of the various licensing bodies, these reforms would not seem to be as urgent as certain others, notably the increase in the number of direct representatives, the raising of the standard of preliminary education, the better protection of practitioners against the competition of quacks, and the regulation of the relationship of medical officers to touting medical aid societies. Though less emphatic in his denunciations, Dr. Glover also recognises the desirability of a revision of the conditions under which registered prac-

tioners are at present left free to ally themselves with these medical aid societies, but he apparently pins his faith to the Conciliation Board, a faith which is apparently not shared by the bulk of his constituents. Doubtless this Board may enable the Council and the societies to tide over pressing difficulties, but we do not believe that it can be trusted to place the matter in a position which will satisfy the general practitioner. It is rather odd that none of the speakers seem to have dealt with the question of hospital abuse which, after all, is a great and pressing evil; indeed, between the open doors of the charity-supported hospital and the omnivorous maws of clubs and medical aid societies, the general practitioner daily finds his sphere of activity circumscribed and his means of gaining a livelihood reduced. Still, we are glad to bear witness to this exhibition of interest in matters which so intimately concern the gravest interests of the profession, and we trust that this meeting may prove epoch-marking in the movement for the consolidation and advancement of the medical profession.

THE LONDON CONJOINT EXAMINATION AND THE L.S.A.

It must be rather difficult for many London students to decide which of the qualifications to choose, the M.R.C.S., L.R.C.P., or the L.S.A. The course of study required to be followed during the five years which must be passed between the dates of registration and qualification is the same very nearly for both the Conjoint and the L.S.A.; and, as far as the examinations are concerned, we believe that there is but little difference between them. We are glad to see that the rivalry between the corporations which have legal power to give diplomas is not so active as it was a short time ago; and the Society of Apothecaries may fairly entertain some hope of carrying on its work as an examining body without fear of extinction in that respect. The old system followed by the majority of students when the Society of Apothecaries had no surgical examination was of course to obtain the M.R.C.S. and L.S.A. Now, however, that is not possible: and as the L.R.C.P. may be regarded generally as superior to the L.S.A., the conjoint diploma must appear to be superior to the L.S.A. alone. Now the question of the difference between the two ought to be considered. The Society of Apothecaries is clearly intended for that great class of practitioners in this country who do not entrust the supply of remedies to the pharmaceutical chemist, but keep in their own hands the dispensing thereof. There are great advantages to the public in encouraging the continuance of this plan in many parts of the country, partly for the sake of economy, but chiefly for the security provided for the work being properly and, above all, promptly carried out. It seems to us that when the intentions of a student are to settle down in country practice, or to go abroad, it is well for him to secure the right to dispense

his own medicines and to obtain the knowledge required to do so. We distinguish three very distinct divisions in the work to which a student must devote himself when preparing for practice, as well as after he is qualified. One is the study of diseases, which of course includes the observation of their symptoms, and their morbid anatomy or pathology. The second class is that to which the general term surgery applies. The third class is the treatment of diseases, and this of course requires knowledge of the properties of agents and their proper use in treatment. We are right, we think, in assuming that it is the object of the College of Physicians to encourage the first class of studies; of the College of Surgeons to encourage the second class; and of the Society of Apothecaries to encourage the third class. But the question of first importance to decide is whether it is to the advantage of the public or not for the practitioner to have the knowledge and right to supply his patients with remedies without having to send them with his prescriptions to a chemist. The English system differs in this respect from the continental system; and we are disposed to take the view that the English system is for the present best suited to the requirements of the public, because it makes adequate provision for the supply of medicines in a multitude of small country districts in which a dispensing chemist could not maintain himself. The continental system gives the chemist more power than is desirable, and we fear that in this country there is a growing tendency for the public to resort to the chemist for advice as well as medicine. If the London Colleges of Physicians and Surgeons were united with the London Society of Apothecaries and had one examination in which the three divisions of study were equally considered, it would be better for all concerned, and then their licentiates would have the right to consult their own interests according as circumstances and the nature of their practice required in dispensing their own medicines or not. Nevertheless we apprehend that there are many who hold the view that the dispensing of medicines by the practitioner, that is an open surgery, must be regarded as a regrettable expedient, essential but bad in principle, and to be got rid of as soon as circumstances permit. On the other hand, there are those who take a different view, and consider that it will certainly be discreet for the practitioner to arm himself with such qualifications as will enable him to provide for his patient's wants.

ALCOHOL IN WAR.

THE practical test of a campaign conducted in a far distant country has been applied to the British military system, with results that are not on the whole unsatisfactory. At the same time it would be idle to deny that various defects have been brought into the light of day. The navy commissariat organisation, for instance, has shown itself worthless so far as providing sound food for the transport ships, and it is to be hoped that when the war is over a

searching Government inquiry will be conducted into this all-important detail of transport work. Then, again, the utter inadequacy of the Army Medical Service to the needs of the situation has been proved to demonstration. A large number of supernumerary civilian, and of Indian army surgeons have been despatched to the seat of war, while the army at home has been depleted of its surgeons. In consequence, civilian medical men have been engaged to undertake the regimental supervision of military stations throughout the United Kingdom. In not a few instances, these important duties, both at home and abroad, have been entrusted to newly-qualified men, who are clearly without the experience necessary to render them competent for such posts. Indeed, with a full sense of this responsibility, we do not hesitate to say that the War Office is not to be envied the heavy risk it is incurring by handing over whole regiments of British soldiers to the care of fledgling medical men, whether the sphere of the latter be at home or at the Cape. All these straits were prophesied long ago, and the War Office authorities have only to thank their own system which has been founded on disastrous lines of social arrogance and false economy. No doubt when the piping times of peace are once more upon us a Government inquiry will find further material for investigation in Army medical administration and organisation. The introduction of aseptic surgery and the perfecting of the medical branch of the Service, to say nothing of the latest wonder, the Röntgen rays, have done a vast deal towards alleviating the horrors of war, and the saving of life from casualties. Perhaps one of the most significant signs of the times may be found in the different place assigned to alcohol in the conduct of modern British warfare. This subject was well discussed in the *Forum* of last May in an article written by Mr. W. K. Rose, the able *Reuter's* correspondent in the Soudan campaign. In the old days, when it was the fashion of our forefathers in every station of life to drink to excess, the practice was carried into active service, whether ashore or afloat. Indeed, it was not uncommon for many battles to be fought by soldiers more or less under the influence of "Dutch courage." But nowadays we have changed all that. The modern general has learnt the lesson that the hardships of campaigning, however inclement or deadly the climate, may best be borne without the aid of alcohol. So long ago as the Indian Mutiny some of the greatest feats of endurance were performed by Havelock's men upon coffee alone as a beverage. In the Red River Expedition of 1870, under General Wolseley, no spirit ration was issued, and it is recorded by the medical authorities that no men could have enjoyed better health than the troops concerned. In the tropical climate of Central Africa the use of rum was formerly regarded as a specific and necessary precaution against the deadly diseases of those regions. The old-fashioned ration of rum, however, was discontinued in the Ashantee war of 1873; also under the command of General Wolseley. The result of that omission was

most encouraging, for the total mortality from all causes amounted to the surprisingly low figure of 3·14 per cent. of the whole strength of the British troops. In the Kaffir war of 1877-78 the use of rum as an ordinary ration was prohibited, and the health of the force engaged was excellent. In the more recent campaign in the Soudan the Sirdar wisely prohibited all alcoholic liquors, and a quantity of villainous smuggled spirit was summarily disposed of by pouring it out upon the sands of the desert. Without alcohol the men engaged in that expedition quickly grew into fine condition as regards general health and endurance. In short, these experiences simply prove that it is not the climate that is so deadly to Europeans as their habits, which, in the case of alcohol, predispose to disease and lessen the powers of resistance and recovery. The growing intelligence of modern times has widely recognised the needlessness of alcohol in everyday life, although there can be no doubt as to its value as a stimulant when administered under proper medical control. In this subordinate and restricted manner alcohol will play its part in the war now being waged in South Africa, but it will not be needed to accentuate or to call forth the splendid and traditional valour which has long made the British soldier the envy of the world.

Notes on Current Topics.

The Present Position of the Vaccination Question.

THE first annual dinner of the Association of Public Vaccinators, which took place on Saturday evening last, afforded a convenient opportunity to Mr. Climson Greenwood, the president, to dilate upon the grievances of public vaccinators, and to Mr. Chaplin, M.P., to discuss the general bearings of the last Act. Little had been heard before of the grievances in question, probably because public opinion was much more concerned with the question of principle than with the working details. The insecurity of their tenure of office, the absence of all control on their part over the vaccination officer and their humiliating dependence on the guardians are so many points calling for reform. The independence of the Medical Officer is at least as important, from an administrative point of view, as that of the vaccination officer whose position has now been judicially defined, thanks to the steps taken by the Local Government Board. The speech of the evening, however, was that of the President of the Local Government Board, Mr. Chaplin, M.P., who prefaced his remarks with an assurance that if it could be shown that the position of a public vaccinator had been prejudiced in any way because he honestly tried to do his duty he would not fail to come forward in his support. After disposing of sundry criticisms on the lymph supply he proceeded to compare the position of things at the time of the passing of the Act, 1898, with that which now obtains. Before 1898, he observed, at least a third of

the local authorities had virtually declined to fulfil their duty in respect of enforcing vaccination, with the result that some 300,000 children remained every year unvaccinated. He declined any responsibility for the introduction of the "conscientious objector," but pointed out that, since the passing of the Act, children had been vaccinated at the rate of 150,000 more per annum. He defended the action of the Local Government Board in respect of vaccination officers, pointing out that many other officials, occupying more or less similar positions, had their duties prescribed for them entirely irrespective of the guardians; indeed, as he effectively pointed out, it is difficult to see how the public interest could be served, or public business carried on, if the central department were to have no authority in these matters. This, indeed, was the only alternative at the disposal of the Government if the Act was not to be allowed to prove a disastrous failure. The right honourable gentleman concluded his remarks with a valuable hint to the supporters of vaccination, as to the value of an effectual propaganda. Why, he asked, did those who were so clamorous against the Government when the Bill was before Parliament not start an opposition, a vaccination league, whose business it would be to explode the fallacies of that other body which had done, and was doing, its best to prevent vaccination, adding that such a league would do more in the cause of vaccination than anything the Government might do.

The End of a Noxious Trade.

THE result of the trial at the Old Bailey last week of the persons trading as "Madame Frain" will, we trust, have the effect of putting a stop to the practices of all those unprincipled persons of the same ilk, whose career so far has been unchecked by the law. In some respects the trial in question has proved a most important one. In the first place it was conspicuous for having been undertaken at the instance of the Director of Public Prosecutions. This undoubtedly showed that the evil with which it dealt had at last been officially recognised, and that the decision had been arrived at to put the law in force against it. Now that one prosecution of the kind has terminated successfully there should not be much difficulty in proceeding in other cases in which the evil flagrantly exists. But it was clear from the elaborate and careful statement of the judge on the law of the case that the legal points involved were not by any means simple. The statement in question was made in reply to the plaint of the defendants' counsel that there was no case to go to the jury against the defendants. The claim was that there was no evidence of criminal attempt. But Mr. Justice Darling took a different view of the case. "I have given," he said, "my best consideration to this matter, and I will state a little fully what my view is, because it is perfectly plain that this case raises, probably for the first time, questions on a very difficult branch of the law—questions as to what is or what is not, in given circumstances, a criminal attempt to do a thing, and how

far a person inciting is or is not criminally responsible. The conclusion I have come to is this, that if the woman, believing that she is taking a noxious thing within the meaning of the statute, does, with intent to procure abortion, take a thing in fact harmless, she is guilty of the attempt to procure abortion within the meaning of the statute. I have also come to the conclusion that if the person inciting the woman to take the noxious drug himself believed that thing to be a noxious drug capable of procuring abortion, he would be guilty of inciting her to attempt to commit the crime, although, owing to facts being otherwise than he believed, the commission of the crime in the manner proposed was impossible." The jury presumably could not fail to be impressed with this expression of opinion, more especially since the evidence showed that the pills sold by the defendants were of a noxious character, and would act as abortive agents if taken in the quantities recommended. In the end a verdict of guilty was returned, and substantial terms of imprisonment meted out to the guilty principals. A second point of great importance in connection with the trial was the deliberate warning given by the judge to all those newspaper proprietors who publish advertisements of the kind which made the business of "Madame Frain." Mr. Justice Darling pointed out that if this practice were continued, the owners of the journals in question might find themselves in the same position as the defendants at the trial. There can be no doubt that the suppression of these advertisements will have a most salutary effect in the prevention of the evil. Moreover, without such temptations to resort to criminal proceedings, unmarried women would be less likely to fall astray; and without such scandalous incentives to crime there would be less inducement to the married to interfere with the course of Nature.

Homœopathy and Surgery.

It is interesting to note that at least *one* homœopathist recognises that there is something better than homœopathy, namely, surgery. In this connection a curious correspondence recently took place between Lord Dysart and the Committee of the Grantham Hospital. Lord Dysart is an ardent homœopathist, and, at the same time, he is a subscriber to the Hospital. In this latter capacity he has offered to double his subscription if the Committee of the institution will undertake to exclude all internal treatment for the patients except in very extreme cases. The noble Earl intimated also that he was desirous in every way of supporting the practice of surgery, but that he intensely disliked supporting an institution which adopted antiquated and unscientific methods of internal medicine, while it was unreasonable to expect him to support a system of medicine, which besides not being up to date, was doing much harm to the public. These are his Lordship's views upon the practice of medicine in the present day, and to say the least they can scarcely be described as compli-

mentary. Most persons, however, we imagine, instead of agreeing with his Lordship on the matter would be disposed to hold that homœopathy was out of date, and not the present-day practice of medicine. We fear Lord Dysart is altogether talking about a subject of which he can have but little knowledge when he expresses himself to the effect that homœopathy is an up-to-date system of medical treatment. No statement could be more absurd. If science has proved anything it has shown that homœopathy is as unscientific as it is now antiquated. It is interesting to record, however, that the committee of the Grantham Hospital replied to his Lordship to the effect that they could not see their way to suggest any alteration in the existing management of the hospital, but they gave their assurance that Lord Dysart's subscription would be devoted entirely to the relief of surgical patients. Possibly this means that the money will be expended in purchasing anti-septic dressings.

The Lesson of a Small-Pox Epidemic.

THE lesson of the last small-pox epidemic in Warrington has evidently not been lost upon some of the inhabitants, as the following incident will show. A man who filled the *role* of "conscientious objector"—applied to the local bench of magistrates last week for a certificate of exemption from vaccination. He was asked by the Mayor if he had been in the town during the last epidemic, and to this query a negative reply was given. Whereupon the Mayor remarked that the epidemic had shown that in proportion as re-vaccination obtained the disease had diminished, and the sad experience which they had had of the ravages of small-pox had taught him that vaccination was a necessary prophylactic. The Mayor then left the Bench, stating that he, for one, would not grant the certificate applied for, but that his brother magistrates could do as they liked. The end was that each of the other magistrates followed the Mayor's leading, and the "conscientious objector" was told that if he wanted his certificate he would have to make an application upon another day. The incident is a significant one from several points of view, and more especially as showing how easily the common sense of these magistrates disposed of one of the most grievous fads of the present day.

The Mauser Bullet.

It is not unnatural that great interest should now be taken in the wounds inflicted upon our soldiers in South Africa by the Mauser bullet. As is well-known, the Mauser rifle is the weapon with which the Boers are chiefly armed, and the present war is the first occasion upon which the effects of its projectile have been seen in European troops. Numerous cases are reported of soldiers wounded by Mauser bullets now lying in the Wynberg hospital. It is stated that an examination of the wounds shows that this bullet makes a cleaner track through bone and soft tissues than the Lee-Metford, and that the aperture of exit is not larger than that of entry. But

if the objection to the Lee-Metford bullet is that it fails to stop "rushes," how does this objection apply to the Mauser, whose wounds seem to be less deadly than the former. The rational conclusion must be that the less the injury inflicted by the projectile the less must be its "stopping" power, and if the Mauser bullet-wounds are less severe than those of the Lee-Metford, unserviceable a weapon as the latter is said to be, the former must be still more so. It will be interesting, after the war is concluded, to learn the opinion of experts upon this matter. It would seem that the modern rifle has reached such a state of mechanical and scientific perfection, that its bullet must injure a vital part before the life of a soldier is endangered. In the days of "Brown Bess" many a trivial wound meant death to the injured man. So, after all, even if war in the present day is conducted upon extremely scientific lines, its effects may be less terrible than in early days from a humane point of view.

The Dublin Conjoint Examinations.

THE report of the July examinations (presented, it will be observed, four months after date, by the Committee of Management) records a decadence in the number of candidates compared with the same period of last year—239 as against 251. An analysis of the figures explains this falling off and is highly instructive for the Dublin teachers. It will be recollected that the College of Surgeons felt obliged, a couple of years ago, to take serious notice of the persistent and excessive rejections in Physiology and Histology at these examinations, with the result that the rejection percentage dropped largely. It would appear that the examiners in these subjects have reverted to their former policy, for we see that, at the second examination in July (at which the subject is predominant) 45.3 per cent. of the candidates were rejected in these subjects alone, the average in all subjects of that examination having been 57.0 per cent. Sixty-nine candidates offered themselves for this examination against 90 this time last year, and it is noteworthy that 9 of these offered themselves in one subject only, presumably most of them candidates having been previously rejected in the same subject.

The Subsoil of Guy's Hospital.

AN extensive find of osseous remains was made a few days since in the "park" within the grounds of Guy's Hospital in the course of the excavation for a gallery which is being constructed for the purpose of providing underground communication between different parts of the buildings. No one knows exactly how these bones came where they were found but not many years ago a similar find was made, no less than a hundred skeletons having been unearthed when digging the foundations for additional buildings. It is surmised that the hospital must have been built on a place previously used as a burial ground for the victims of the plague, and its position just outside the city boundaries gives some credence thereto. We are informed that a Dutch auction was held, but

the remains fetched very poor prices, skulls going for twopence, while the long bones were simply "given away." It is reported that a large number of short clay pipes were found in the neighbouring earth, but their presence is as much a mystery as that of the bones, seeing that a plague victim would be unlikely to take his "cuddy" along with him when conveyed to his last resting place; or, as it turns out, his last resting place but one.

A Medical Hero in the Transvaal War.

SURGEON-CAPTAIN R. A. BUNTINE has recently performed a valiant deed under Boer fire. He was with the Natal Carabiniers who were patrolling the Free State border when the party was surprised by ambushed Boers at Bester's, near Van Reenen's Pass, under the towering peak of the Drakensberg. The Carabiniers had to retire, leaving a wounded trooper on the ground. Dr. Buntine, inducing his trooper servant Duke to accompany him, rode back

and having dismounted, placed the severely wounded man on his own horse, and then, in spite of the rifle practice, clutched hold of his servant's stirrup leather and ran back to camp, all three men getting in safely. For this conspicuous deed of courage in the face of the enemy he has been mentioned in despatches, and is likely to get the much coveted V.C. Our special correspondent informs us that Dr. Buntine is in private practice at Pietermaritzburg, joined the volunteers with his partner, Dr. Currie, and has been attached to the headquarters' staff of the Royal Army Medical Corps at Ladysmith. He is an Australian, born at Melbourne, and is of Scottish extraction.

WE are requested to inform our readers that the Conjoint Diploma in State Medicine heretofore granted by the Royal Colleges of Physicians and Surgeons, Ireland, will, in future, be styled the "Diploma in Public Health."

The Small-pox Epidemic at Hull.

IN spite of the greatest activity the sanitary authorities at Hull cannot as yet be congratulated on having circumscribed the epidemic of small-pox which has been raging there for some weeks past. The number of cases under treatment up to the present is not far short of 500, and the evil is not limited to the town itself, the existence of such a large focus of infection constituting a standing menace to the neighbouring country with its many agglomerations of human beings, as the returns already show but too plainly. One satisfactory feature is the readiness with which persons of all classes of society avail themselves of the facilities for revaccination, some forty thousand having already been revaccinated. It could be wished, however, that people would adopt this very useful precaution beforehand, without waiting to be scared into compliance by the presence of the disease in their midst. It is impossible to over-estimate the cost to a seaport or manufacturing town of such a widespread epidemic, to say nothing of the suffering and misery which it entails far beyond its own limits. We shall be in a better position to discuss this point when we are in possession of the Government report. Just at present we are more concerned with the means of preventing its extension, and the public may feel assured that nothing that can be done with this object in view has been left undone.

The General Medical Council.

THE autumn session of the General Medical Council was opened yesterday (Tuesday) by the usual presidential address. It is anticipated that the duration of this session will display the same tendency to prolongation as its immediate predecessors, many matters of considerable importance to the profession being comprised in the *agenda* drawn up by the Executive Committee.

The Princess of Wales's Hospital Ship.

THE inspection by the Prince and Princess of Wales of the hospital ship which bears the Princess's name was naturally the occasion of a popular demonstration on Wednesday last at Tilbury. The well-known tourist steamer "Midnight Sun" has been transformed beyond recognition. Her white sides bear the large red cross of Geneva, and the sign is reproduced on the smoke stack and bows. Down below, the cabins and saloons have given place to true hospital wards filled with rows upon rows of suspended beds soon to be filled with their burdens of wounded and suffering soldiers. The nursing sisters and assistants were paraded, and the Prince in a few well-chosen words wished them God-speed on their mission of humanity. The medical visitors could not but admire the perfection of the arrangements made for the reception and treatment of the victims of duty. Every appliance known to modern medical and surgical science has been pressed into the service, of which steam disinfectors, an electric laundry, Röntgen ray apparatus, and a most elaborate and

complete installation for the electric light are but outward and visible indications, showing the care, skill, and thoroughness with which the hospital ship has been fitted up.

A Student Blackmailer.

A FOREIGN exchange relates an instance of what we may term up-to-date blackmailing. A student was recently arrested at Gratz on a charge of endeavouring to obtain money by menaces from an old lady whose dwelling he threatened, failing cash, to inundate with a selection of pathogenic microbes. It is even stated that when searched the ingenious but indelicate student was found in possession of cultures of cholera, tetanus and typhoid fever bacilli. This is quite a novel application of bacteriological knowledge but hardly one which can be commended for imitation.

"Grammar School" Education in Professional Education.

THE attempt on the part of the London Colleges to evade the regulations of the General Medical Council by recognising the sham instruction given at grammar schools in chemistry, physics, and biology is likely to occupy the attention of the General Medical Council at a prolonged debate at the session which opened yesterday. It is unnecessary to discuss the merits of this question, considering that the Education Committee of the Council has already pronounced twice, and the Council itself once, that these grammar school courses are a palpable evasion of the regulations, and it is not likely that they will go back from that pronouncement; but it is as well to say that we believe that, if the London colleges are permitted to accept such courses, the Irish and Scotch colleges, which have hitherto rejected them, will receive certificates from any school which purports to give instruction in these subjects, and, in that case, the Medical Council may as well strike them out of the curriculum altogether, a consummation, indeed, which would not distress us very much.

The Dublin Preliminary Examination.

IN our last issue we referred to the excessively high standard of the Dublin conjoint preliminary, which the General Medical Council is seeking to crush out, as compared with other examinations, which it readily accepts. We have since made inquiries, and are in possession of the name of at least one candidate who, having tried the Dublin preliminary four times, and made overtures to another body which would not be accepted, went down the street to a university close-by where he paid £15, and passed the examination recognised by the Medical Council, and is now inscribed on the Students' Register. The theory of the Medical Council that, outside the universities, there is no educational salvation is not sustained by the facts.

Anti-Typhoid Inoculation in the Army.

DESPITE the fact that the South African climate in which the war is now being carried on is the best in

the world, and the risks of typhoid infection correspondingly slight, nevertheless, many thousands of our soldiers have wisely submitted to inoculation against typhoid. This is as it should be, for even in places where this fatal disease is least to be expected, as, for example, in the open veldt, it is well to be on the safe side, and be prepared for any infection that might be present. So far, we believe, the death of only one private has been reported from typhoid, and this occurred in an up country station before the inoculated troops were sent out. Upon the whole then, although for the reasons above given, the present occasion cannot be regarded as one in which the antityphoid inoculations will be likely to be put to a satisfactory test, nevertheless after the war is over some facts will probably be forthcoming to show to what extent they have been useful.

The Medical Advisers of the Czar.

A FRENCH contemporary draws attention to the number of medical advisers "engaged" by the Czar of Russia. They number in all no fewer than twenty-seven, thus forming a veritable medical body-guard. There is first a physician-in-chief; then come the honorary physicians, three surgeons, and four honorary surgeons; two ophthalmic surgeons, a chiropodist, and honorary chiropodist; also two court physicians and three specialists for the Czarina. This goodly array of medical talent, for it represents the best that Russia can produce, should make the Czar happy in his mind so far as his medical requirements are concerned. There is said to be safety in numbers, but this old saying is thought not to apply to cases in which many medical men assemble around the sick bed of a patient.

Nursing in the City of Dublin Hospital.

OUR advertising sheet informs us to-day that the City of Dublin Hospital has decided upon a change in its nursing system. Heretofore, its nursing has been done by an institute, which may be said to have been proprietary located close by, but the Governors have now decided to have a nursing establishment of their own, and they are now making provision for the accommodation of the staff by temporary, and afterwards by permanent, extensions of the hospital buildings.

PERSONAL.

SIR WILLIAM BANKS will preside at the annual dinner of the students of University College, Liverpool, on December 2nd.

PROFESSOR KOCH, who is now in Batavia, is reported to be in good health. He will continue his observations on malaria a few months longer, and will then proceed to New Guinea.

DR. FRANK J. WETHERED, late Medical Registrar and lecturer on Medical Jurisprudence at the Middlesex Hospital has been elected Assistant Physician to that Institution.

DR. CARSTAIRS CUMMING DOUGLAS has been appointed Professor of Medical Jurisprudence in Anderson's College Medical School, Glasgow. Dr. Douglas is a graduate of Edinburgh University, where he took his degree in medicine with first-class honours and the Etches scholarship in 1890, and his degree in Science (Department of Public Health) in 1891.

OUR Continental correspondent informs us that King Alexander of Servia is at the popular winter health resort of Meran, South Tyrol, Austria. His Majesty resides at the Schloss Rametz, in the elevated Obermais suburb of Meran, and is accompanied by General Solárovich, Major Wassies, Colonel Androvitch, and Doctors Weljkovics and Michel.

THE German Empress Frederick (Princess Royal of Great Britain), with her daughter, Princess of Saxe-Meiningen, is at the Imperial Hotel Trento, Trient, South Tyrol. Her Majesty frequently visits Meran, Arco, Riva, Gardone-Riviera, and other places of interest conveniently near Trient. Our correspondent understands that she intends building a château on the Cap San Vigilio, Lake Garda.

SIR WM. MACCORMAC, Bart., and Mr. Makins, of St. Thomas's Hospital, London, have arrived in South Africa, and after a thorough inspection of the hospital arrangements for the sick and wounded at the seat of war, have pronounced very favourably upon the energy and foresight shown by those in charge of the hospitals and with the work already accomplished by the Army Medical Corps.

DR. JAMES ALEXANDER LINDSAY, of Belfast, who has been appointed to the chair of medicine in Queen's College Belfast, is an *alumnus* of the college, and he secured many distinctions there. After leaving Belfast he studied in the leading schools of London and the Continent. He is a member of the more important medical bodies, and a much-esteemed medical writer. His "The Climatic Treatment of Consumption" is regarded as a text-book.

DR. EMILY WINIFRED DICKSON, being engaged to be married in the early part of December, has resigned her position as gynaecologist to the House of Industry Hospitals, Dublin, and Dr. Thomas Henry Wilson has been appointed as her successor. Dr. Wilson has recently occupied the position of Senior Assistant Physician to the Rotunda Hospital. Dr. Dickson has also lately resigned her office of Assistant Physician to the Master of the Coombe Lying-in Hospital.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

UNIVERSITY JOTTINGS.—GLASGOW.

THE number of students matriculated at Glasgow University this season is 1569, an increase of 38, as compared with the preceding year.

In the Randolph Hall on Thursday evening, 24th inst.: Principal Story gave an "At Home." This step is quite an innovation, as no former Principal ever used the building for such a function. On this occasion fun and frivolity assumed the place of serious faces and palpitating hearts. Gilmorehill did not quite under-

stand or know itself; tea and claret cup were in evidence instead of pens and ink. Such functions, it is said, will be given by the Principal during the session. In fact, the session has begun with a series of festive gatherings. A short time ago the students were at loggerheads with Professor Ramsay, who magnanimously apologised to them, and since then has entertained them to tea in the Examination Hall of the University. On another evening Professor Murdoch Cameron gave a "smoker at home" to the medicals in the Union, which was no doubt immensely enjoyed, and if the "going home" at an early hour be regarded as a reflection of the gathering, then it is safe to say it was *very lively*. Brother Pelican says Dr. Cameron is a born *storyteller*; this statement is a fact, and the professor would thoroughly enjoy himself, as he would be in his "element" while giving utterance to his *stories*, especially those of a cerulean colour. After enjoying such a feast of light things, the students were further treated on another evening to hear Dr. McVail, Health Officer for the counties of Stirling and Dumbarton, read a paper on "Municipal Duty as to Prevention of Tuberculosis." While such things were going on at the University the members of the Glasgow and West of Scotland Agricultural Discussion Society were treated to a lecture by Dr. Robert Bell on "Potato Disease." It is to be hoped that the "pregnant week" was safely delivered of its weighty burden, and was satisfactory to all concerned.

GLASGOW HOSPITAL SUNDAY took place on the 26th (Sunday) inst., and, as usual on such occasions, the day was wet and stormy, preventing many charitable souls from going out and giving their support. Last year 355 churches gave collections, an increase of eight on the year previous, and the total (including Sunday schools) amounted to £4,388 16s. 11d. The circular issued states that the three principal infirmaries treated 12,991 patients in their wards and 45,188 in their dispensaries, a total of 58,179. On such Sundays when the weather prevents a full congregation, the public are reminded that their subscriptions can be sent to the Secretaries, which, no doubt, will be the case this time.

MEDICAL SOCIETY OF LONDON.

THE meeting on Monday evening last (November 27th) was devoted in its entirety to a paper by Dr. Cayley on "Prognosis in Appendicitis, with notes of 200 Cases," and the discussion thereon. He discussed prognosis according as it bore on (1) recovery, and (2) recurrence. He admitted that statistics were misleading in the aggregate, the prognosis having more to do with the special form of the disease. The two essential factors in prognosis were (a) the nature and course of the appendix lesion regarded from the point of view of relative infectivity, and (b) the extent and nature of any resulting peritoneal infection which depended for the most part upon the actual lesion of the appendix, in part also on its position and on certain special modifying conditions. The most important direct prognostic factor was the peritoneal one. Of 200 cases at St. Mary's Hospital, 99 were simple appendicitis, *i.e.*, localised and non-suppurative, all of which recovered; 31 were cases with localised suppuration, of which number 29 recovered; 23 were complicated by general peritonitis, of which 20 died; 42 were examples of relapsing chronic appendicitis, in 37 the appendix was removed, and all the 42 recovered. In the other 5 cases there were special complications, and of these three died. These cases show the great fatality of appendicitis with general peritonitis, the small mortality of appendicitis with localised abscess, if properly treated, and the almost uniformly favourable course of mild cases, which constitute the majority of all cases of the disease. The special prognostic indications for clinical consideration were (1) local symptoms, with special reference to pain and vomiting; (2) general symptoms, with special reference to temperature, pulse, respiration and general condition; (3) local signs on physical examination; and (4) the progress of the case. Persistent, severe pain suggested a severe lesion, and a sudden increase of pain an unfavourable turn. Vomiting, when persistent and severe was always a significant symptom. The temperature

chart by itself is a fallacious guide, but taken in conjunction with the pulse, respiration, &c., it possesses considerable prognostic import. A high pulse rate is of bad omen, as is also a bad general condition. The character of the local signs is also of considerable importance. Above all we must note the progress of the case during the first twenty-four hours in acute cases. In respect of recurrence this may be expected in fully a third of the cases, most commonly within a year of the initial attack, and it amounts to a practical certainty if there is persistent pain, tenderness or local thickening indicative of chronic appendicitis.

In the discussion that ensued Mr. Edmund Owen agreed that suddenness of onset was of grave significance, and urged that the sooner these cases came into the surgeons' hands the better. He dismissed McBurney's point as utterly misleading and useless. Dr. F. Smith pointed out that the cardinal point to investigate was the occurrence or not of suppuration, and in its absence he thought it might be safe to temporise. Mr. Carless urged that surgeons ought not to wait for, but to anticipate, suppuration, thereby obviating the risk of peritonitis. This plan, moreover, enabled them to remove the appendix, which was often impossible in presence of abscess.

Mr. Mansell Moullin thought that in all cases of appendicitis, if no improvement took place within the first thirty-six hours, it was time for the surgeon to intervene, inasmuch as either suppuration had taken place or adhesions were forming which would render relapse inevitable.

Mr. Berry said he had changed his views, and was now an ardent advocate of the more expectant treatment. He adduced some very telling figures showing the results of the various methods of dealing with the disease, and among them he mentioned thirty-three cases of acute appendicitis treated by free incision and washing, of which number twenty-six died, while of forty-one dealt with by limited incision through adhesions only two died. He protested energetically against the fatal practice of washing out the abdomen, which, he thought, was responsible for many of the fatal results, and he pointed out that in the majority of cases an incision through the linea semilunaris would fail to open an appendicular abscess. The incision adopted in the majority of the successful cases was one perpendicular to, and just above, Poupart's ligament.

The President said he had seen a very large number of such cases recover under common-sense medical treatment, but he always called in a surgeon to have the benefit of his opinion.

Dr. Cayley then replied, admitting that early operation had much to recommend it if one could be sure of getting the cases early enough and of operating at the right moment, but he asked whether an operation at an injudicious moment might not have for effect to convert a local into a more general infection.

Obituary.

DR. JOSEPH SAMUEL PRENDERGAST.

DR. J. S. PRENDERGAST, the son of the late Francis Prendergast, for many years Registrar of the Court of Chancery in Ireland, was born in 1810, entered the Army in 1836, and retired in 1863 with the honorary rank of Inspector-General of Army Hospitals. He was attached to the 77th Regiment. He served in the Crimean campaign upon the personal staff of the Field-Marshal Commanding-in-Chief, Lord Raglan. He was present at the battles of Alma, Inkerman, and Balaklava, as well as at the siege of Sevastopol. He attended Lord Raglan in the field until his death, when he accompanied his body to England. He received the Crimean medal with four clasps and Turkish medal (5th class of Medjidieh).

MR. W. I. WHEELER, B.A., F.R.S.C.I., OF DUBLIN.

THE grave illness of this surgeon, which we reported in our last issue, ended on Saturday last when he died at his residence, Merrion Square, Dublin, of a complication of diseased conditions of which typhoid was the most mani-

fest. Mr. Wheeler has been a leader in Dublin surgery for many years. He received his first qualification from the Colleges in 1866, and became Fellow of the College of Surgeons in 1874 and M.Ch. of the University of Dublin in 1879. Having served as Resident in the City of Dublin Hospital he became a Demonstrator in the School of the College of Surgeons, and afterwards entered the Army Medical service and saw service in the Abyssinian campaign. He, on his return home started practice in Dublin, being elected as Surgeon to the City of Dublin Hospital, a position which he held until his death. He also served as Examiner in Surgery in his College, and became its President in 1883.

MR. FRANK SHAPLEY, M.R.C.S., OF SIDCUP.

THE death of Mr. Frank Shapley took place on the 15th inst. from typhoid fever. He had been suffering from a severe attack of rheumatism for a month past, but was progressing favourably until the beginning of November, when typhoid supervened, to which he succumbed at the early age of 42. Deceased was a student of the London Hospital, took the L.S.A. in 1878, and the diploma of M.R.C.S. Eng. in 1879. He was senior house surgeon of the London Hospital, assistant medical officer to the Wonford Hospital for the Insane, Exeter, and later senior assistant medical officer at the Glamorganshire County Asylum. In 1884 he commenced private practice at Sidcup, in Kent, and during his residence there, of fifteen years, has taken a prominent part in all local affairs, and it was owing to his exertions that the present Cottage Hospital, to which he was attached as honorary medical officer, was freed from debt.

DR. CAMARA PESTANA.

A CORRESPONDENT of the *Times* gives some pathetic details of the death of Dr. Camara Pestana, who, it is stated, actually caught the plague through his anxiety to learn all that he could about it. He was dissecting the body of a patient who had died from plague, and in order to extract the virus more thoroughly for analysis he put aside his instruments and worked with his fingers. The poison entered his system under the finger nails and he was struck down with the terrible disease which he was investigating. He was at once moved to an isolated ward set apart for plague sufferers, and there he set himself to study his own case and to record for the benefit of humanity his own symptoms and the course of the disease. He refused to see his brother for fear of infection, and in every way, even in making arrangements for his own funeral, he took every precaution to prevent the spread of the plague. His mind and will conquered his bodily sufferings until the very end, and even as he died he was still trying to indicate to those around him the lessons of his own case. He left a letter for the Queen of Portugal begging for her influence in favour of his colleagues at the Lisbon Bacteriological Institute. So died the heroic doctor, who, as our correspondent says, "had toiled for months amid the horrors of the plague hospital and dissecting room, and at last gave his life a willing sacrifice for the benefit of the whole world."

MR. WM. LEWIS MORGAN, M.A., M.R.C.S., OF OXFORD.

News has just reached here of the death at sea about a fortnight ago, of Mr. W. Lewis Morgan, a well-known Oxford surgeon, at the early age of 45. Early in the year his health had completely broken down, and he left England for the Cape with the hope that the voyage would lead to a marked improvement in his condition. While on the return voyage, however, dangerous symptoms set in to which he succumbed, and he was buried at sea. Mr. Morgan was one of the University coroners, and performed valuable work as an honorary surgeon of the Radcliffe Infirmary. Before his departure from England, the Freemasons, in recognition of his services as provincial grand secretary of Oxfordshire, presented

him with a purse of 500 guineas. As a student he greatly distinguished himself, attaining first-class honours at Oxford University in Natural Science. Later on he became a member of the Board of the Faculty of Medicine and Litchfield Lecturer on Clinical Surgery in the University.

INCONSISTENCIES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Edward Berdoe, the medical apostle of the anti-vivisectionists, attempts to apologise for the complacent inaction of his party with reference to the torturing of tame deer by Her Majesty's Buckhounds, by pointing out that an obscure clergyman in an obscure parish in England, who is an anti-vivisectionist, has written something against this so-called "sport," and he says, "tell us what more we (the antis) can do in the matter and we will do it." I suppose it is unnecessary to answer the question. Dr. Berdoe and his cogeners are perfectly well informed as to what they might do if they wished. None are better skilled in the art of working up a semi-political agitation among benevolent old parsons and impressible old ladies and carrying that agitation, with their money, into the constituencies and into the House of Commons, and it is not at first obvious why they pass over the atrocities perpetrated in these Buckhound hunts, in the transhipment of cattle, and in the marketing of fowl, and many other every day cruelties, and devote themselves to mendacious attacks on the medical profession for putting a hypodermic injection under the skin of a frog, or performing other equally painless experiments. On consideration, however, their attitude is not difficult to understand. Anything associated with Her Majesty's name would be unpopular with the old women, male and female, whom the organisation serves, and any agitation for interference with cattle commercial interests would be scouted by Parliament, so that Dr. Berdoe and his friends wisely confine themselves to maligning the doctors and scientists, who, politically, have no friends. No one can have any respect for the consistency of a party who occupy themselves with the endeavour to swallow camels while they strain at gnats.

I am, Sir, yours truly,

MAWORM.

OPERATIONS AT THE CANCER HOSPITAL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly permit an outside general practitioner to make a few comments on two cases reported in last week's edition as coming from the Brompton Cancer Hospital. The first case by Mr. Ryall gives a history of ten years. Surely this is enough to put it out of the class of operative cancer cases. The next case is by Dr. Snow, and gives a history of five to six years. This surely puts the case of a woman of 38, full blooded and vigorous, out of the list of cancer patients. Yet both were operated on at a hospital supported by the outside public for cancer cases alone. There are many cases, as we all know, where no one can be quite certain whether they are malignant or not, but neither of these cases comes under the category or definition of cancer. I do not suggest that the treatment, although unsuccessful, was wrong, but I do most emphatically say that neither should have been treated at a Cancer Hospital. It is obtaining money by false pretences to get it from the public for supporting cancer cases, and then applying it to myoma and other diseases.

I am, Sir, yours truly,

JAMES HAMILTON,

60, Sydney Street, Chelsea, S.W.

November 25th, 1899.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

REPRINTS.—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them, at half the usual cost, on application to the printers before the type is broken up.

A HINT TO SCULPTORS.

A CORRESPONDENT suggests that the refuge in front of the Jenner Institute offers a magnificent position for a statue of "Bacteriology Enlightening Therapeutics," and suggests that sculptors might give the suggestion their attention. The idea is ingenious, but still more ingenious would be the artist who could work out the suggestion in marble.

THE BITER BIT.

THE following amusing tale was recently told to his class by Professor Comstock, of Cornell, in speaking of the trials of scientists. It appears that a professor of invertebrate zoology in a sister university wished to procure some trichinous pork for purposes of experiment. The learned scientist went to his butcher and asked him if he ever got any measly pork. "Sometimes," the butcher cautiously answered, "but I always throw it away." "Well," said the professor, "the next time you have any I wish you'd send me up some," meaning, of course, to his laboratory. The butcher, although somewhat taken aback, said that he would. Three weeks passed, when the professor, growing impatient, again visited the store. "Haven't you found any measly pork yet?" "Why, yes," said the butcher, "I sent up two pounds a week ago." A sickly grin broke over the professor's face. "Where did you send it?" "Why, to your house, of course," said the butcher.—*New York Medical Record*.

MR. G. C. GREEN.—Is thanked for his suggestion, but no useful purpose is served by a record of such cases.

DR. KNOTT's paper on "Lactation in the Virgin, the Old Woman, and the New-born," will appear in our next.

AN UNCONSIDERED TRIFLE.

"ARE you fond of literature?" he inquired, with assumed carelessness, but he was watching her attentively. "Passionately," she replied, "but I get so little time to read anything except the chronicles of my profession. Ours is a most exacting art, but I love books dearly." "Then you must admire Sir Walter Scott? Is not his 'Lady of the Lake' exquisite in its flowing grace and poetic imagery?" "It is perfectly lovely," she assented, clasping her hands in ecstasy. "I suppose I have read it a dozen times." "And Scott's 'Marmion'?" he continued. "It is perfectly grand," she murmured. "And 'Scott's Emulsion'?" he continued, hastily, for a faint suspicion was beginning to dawn upon him. "I think," she interrupted, rashly, that its the best thing he ever wrote."—*Exchange*.

DR. JAMES EDMUNDS' paper on "Alcohol in Medical Practice" is unavoidably held over.

DR. RABAGLIATI (Bradford)—Your paper on "Suppurating Pelvic Cellulitis, with Remarks on the Occurrence of Low or Sub-normal Temperatures," is marked for early insertion.

Meetings of the Societies and Lectures.

THURSDAY, NOVEMBER 30TH.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL (Gray's Inn Road, W.C.).—5 p.m. Dr. D. GRANT: Treatment of Diseases of the Nasal Sinuses.

FRIDAY, DECEMBER 1ST.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover Square, W.).—5 p.m. Cases and Specimens will be shown by Sir Felix Semon, Dr. Powell, Dr. Bronner, Dr. Waggett, Dr. Pegler, Mr. Butlin, Mr. Boughton, Mr. Wingrave, and others.

SOCIETY OF ANESTHETISTS (20, Hanover Square, W.).—8.30 p.m. Dr. Walter Copestake: A Combined Inhaler for Ether, Chloroform and A.C.E. Mixture.—Clinical Cases by Mr. McCardie, Mr. R. W. Lloyd, Mr. Turle Bakewell, and others.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith).—8.30 p.m. Cases by Mr. McAdam Eccles, Mr. Bidwell Mr. Keetley Dr. George Johnston, the President, and others.

Vacancies.

Bradford Poor-Law Union.—Two Resident Assistant Medical Officers for the Hospital and Workhouse of the Union. Salary of Senior £150, and of Junior, £100, with prescribed rations, washing. Apply to the Clerk to the Guardians, Manor Bow, Bradford.

County Council of Salop.—County Medical Officer of Health. Salary £750 per annum, to include travelling expenses. Applications to Mr. E. C. Peale, Shirehall, Shrewsbury.

Flintshire Dispensary, Holywell.—Resident House Surgeon. Salary £130 a year, with furnished house and coal light, and water.

Manchester Royal Infirmary.—Resident Medical Officer for one year, unmarried. Salary £150, with board and residence.

North Staffordshire Infirmary and Eye Hospital, Hartshill, Stoke-on-Trent.—House Governor and Secretary. Salary £300 a year, non-resident.

Parish of St. Pancras, London.—Senior Assistant Medical Officer for the Workhouse. Salary commencing at £125 with residential allowances. Also a Junior Assistant Medical Officer. Honorarium £80, and residential allowances. Apply to the Clerk to the Guardians, Vestry Hall, Pancras Road.

Pontefract General Dispensary and Infirmary.—Resident Medical Officer. Commencing salary £150 per annum, with furnished rooms, fire, lights, and attendance.

Queen's County Infirmary.—Medical Officer. Salary £182 6s. 2d. per annum. Applications to Chairman of the Infirmary Committee. (See advt.)

University of Edinburgh.—Additional Examinerships in Materia Medica and Clinical Surgery. Salary of the Examiner in Materia Medica £75 per annum, and that of each of the Examiners in Clinical Surgery, £50 per annum. An allowance of £10 per annum given conditionally.

Victoria Infirmary of Glasgow.—Superintendent and Resident Medical Officer. Salary £300 per annum, with board in the Infirmary and a free house.

Appointments.

DOUGLAS, CARSTAIRS C., M.D., B.Sc.Ed., Professor of Medical Jurisprudence, Anderson's College Medical School, Glasgow.

FENN, C. E., M.B., M.R.C.S., L.R.C.P., House Accoucheur to King's College Hospital, London.

FERGUSON, J. M., L.R.C.P., L.R.C.S.Ed., Medical Officer to the New Sanatorium for Infectious Diseases, Burnley.

HADLEY, F. A., M.B.C.S., L.R.C.P., Assistant House Physician to King's College Hospital, London.

MACKAY, HUGH J. D., L.R.C.P., L.R.C.S.Edin., L.F.P. & S., Medical Superintendent of Aston Hall, Warwickshire.

MAYON, S. M., M.R.C.S., L.R.C.P., House Surgeon to King's College Hospital, London.

McMULLEN, W. H., M.R.C.S., L.R.C.P., Junior House Physician to King's College Hospital, London.

ROBERTS, G. A., M.B.C.S., L.R.C.P., Senior House Physician to King's College Hospital, London.

SAVAGE, W. GEORGE, B.Sc., M.B., L.R.C.P.Lond., M.R.C.S., D.P.H., Bacteriologist and Lecturer at the Cardiff and County Public Health Laboratory.

STRATFORD, H. B., M.R.C.S., L.R.C.P., House Surgeon to King's College Hospital, Lincoln's Inn Fields, London.

STUART, HACKWORTH, M.R.C.S., L.R.C.P., Assistant Resident Medical Officer to the London Temperance Hospital.

TWENTYMAN, J. M., B.A., B.Sc., L.S.A., Assistant House Accoucheur to King's College Hospital, London.

VOSPER, P., M.R.C.S., L.R.C.P., House Surgeon to King's College Hospital, London.

YARDMAN, W., L.R.C.P., L.R.C.S.Edin., L.F.P.S.Glasg., Medical Officer for the Third Sanitary District of Manchester.

Births.

DODD.—On Nov. 21st, at 14, Goldstone Villas, Hove, the wife of Arthur H. Dodd, L.R.C.P.Lond., M.R.C.S.Eng., of a daughter.

WISE.—On Nov. 20th, at 39 Mount Pleasant Road, Tunbridge Wells, the wife of Christopher Wise, M.D., of a son.

WHICHER.—Nov. 24th, at Midsomer, Norton, Somersetshire, the wife of A. Hastings Whicher, M.R.C.S.Eng., of a son.

WOODS.—On Nov. 17th, at Westbury, Hornsey Lane, N., the wife of Hugh Woods, M.D., of a son.

Marriages.

BRODIE-HOSEORD.—On Nov. 23rd, at St. Anne's Church, Eastbourne, Norman Brodie, M.A. (Oxon) Indian Civil Service, to Edith Josephine Ainslie, younger daughter of T. Stroud Hosford, L.R.C.P., M.R.C.S., Eastbourne.

SMITH-PULLIN.—On Nov. 22nd, at St. Augustine's Church, Honor Oak, Walter H. M. Smith, L.R.C.P., M.R.C.S.Eng., eldest son of Dr. Smith, Croydon, to Florence Emily, daughter of Joseph Shurly Pullin, of Honor Oak.

Deaths.

HICKS.—On Nov. 18th, at Hendon, Henry Hicks, M.D., F.R.S., aged 62 years.

LAKEMAN.—On Nov. 14th, at 30, Church Street, Modbury, Thomas Lakeman, M.R.C.S., L.R.C.P., aged 34.

SHAPLEY.—On Nov. 15th, of typhoid fever, Frank Shapley, M.R.C.S., L.S.A., of Maison Rouge, Sidcup, Kent, aged 42.

WALKER.—On Nov. 11th, at Margate, Frederick Hanson Walker, M.R.C.S., L.R.C.P., of Blagdon, Putney, aged 31.

A SCIENTIFIC BASIS OF ORGANOTHERAPEUTICS. (a)

By Prof. P. F. RICHTER, M.D.,
Of Berlin.

[FROM OUR OWN CORRESPONDENT.]

THE author connected the new foundation of organotherapeutics with Brown-Séquard. It was based on the assumption that material is furnished by the individual organs, which taken up into the blood is indispensable for the organism. Brown-Séquard's prophecy as to the therapeutical value of the products of organs had to a certain extent been fulfilled. But with numerous failures, the enthusiasm at first excited had subsided, and the strangeness of the thing, along with other considerations had made thoughtful physicians sceptical. But exact scientific inquiry had to search out the healthy kernel from a mass of outgrowths. In the scientific testing of the justification of organotherapeutics, it must be determined by artificial laboratory experiment, what results will happen when certain functions cease, and how far the substitute of the missing organ can remove the symptoms induced by its loss. Organotherapeutics constituted a substitution method, and furnished a substitute for a definite material that was missing from the system. That the incorporation of certain organs did exercise a certain pharmacodynamic action as tonics, &c. (nuclein), might well be assumed, but not as organotherapeutics in the sense of Brown-Séquard. Only thyroid-therapeutics were able to stand up against this general statement. It was undoubtedly true that the removal of the thyroid causes serious disturbances that could be wholly or in part got rid of by the substitution of the organ removed. The conditions were more difficult in the case of the other organs: spleen, bone, marrow, kidneys, suprarenal capsules, pancreas, hypophysis, &c. In contrast to this absurd employment the use of the sexual glands from which Brown-Séquard started lent itself more simple and readily to experimental inquiry. Whilst the removal of most organs was impracticable and dangerous, that of the sexual organ was simple, easy, and free from danger. As regarded the effects of removal of these organs, there had been a fulness of observation for thousands of years, especially in

the case of women whose ovaries ceased to functionise at the climacteric. It was a happy thought of Dr. Leopold Landau to treat the affection of the menopause after analogy with the thyroid, with ovarian substance. The action of the remedy was, however, tested empirically, the theory was swaying in speculation and hypotheses. The influence of the ovaries on the uterus was known, their influence in osteomalacia, on the excretion of phosphorus. Beyond this the matter was too uncertain for any opinion to be founded upon it. On the other hand the influence of the removal of the sexual glands on the deposit of fat was better known. The connection between embonpoint and the climacteric was so striking that it was part of the folk-lore, and had been made use of for ages in the fattening of animals. A critical view of the literary material bearing on natural and artificially anticipated change of life confirmed this assumption of a connection between absence of sexual function and development of fat, and this, independent of other factors, favouring such development. In order to ascertain if there was any scientific basis for this, the gases were accurately measured before and after castration of animals. The experiments were performed on tracheotomised bitches by Hr. Loewy and himself, and the observations extended over several weeks and months. At first no change was observable, either in body weight or gas elimination; but gradually, months after the castration, the weight increased, and a distinct limitation of the gas exchange pro kilo. took place (up to 20 per cent.). From four to six months afterwards the gas exchange remained at its low level. Similar conditions followed in the male dog after castration. To see the effect of supplying the missing function, whether oxydation would be increased, the animals were now given testicular substance, and it was seen especially in the female. One bitch was given, 14 weeks after castration, 8 oöphorin tablets per day, so that in 12½ days 100 were taken. The effect was remarkable. The gas exchange reduced by the castration was not only raised again, but far beyond the original measure, and the increase was not limited to the time she was taking the tablets, but continued for 11 days, and then gradually fell away again. In the castrated male animal substituted testicular substance or spermin drove up the lowered gas exchange, but only to a slight degree. But on the other hand, the action of the oöphorin was extraordinarily extensive. The maximum of gas exchange exceeded the normal by 24.8 per cent., and that of the castrated animal by 44.5 per cent. Given to healthy non-castrated animals, oöphorin did not increase the gas exchange. The proof that oöphorin only acted as a substitute after removal of the several organs was of great value as a scientific basis for organotherapeutics, as such a substitution therapeutics had never been demonstrated before, not even in the case of the thyroid. A castrated bitch given other animal substances (sperminum-Pöhl, testicular substance) showed no rise of gas exchange.

THE ROLE OF THE BLOOD-SUPPLY IN MENTAL PLEASURE AND PAIN. (a)

By WILLIAM R. DAWSON, M.D. F.R.C.P.I.,
Medical Superintendent of Farnham House Asylum, Finglas, Dublin.

AFTER some introductory remarks, Dr. Dawson went on to say that a great change had taken place in the position occupied by the alienist speciality, which now ranked with the rest of the profession. The change was due mainly to an altered conception of mental disease; this having come to be regarded as a symptom of physical disease, and to be dealt with as such. This altered standpoint was rendered tenable by the more recent results of neurological work, especially that Flechsig, along with the products of research conducted by the methods of Golgi and of Nissl, on which the speaker touched at some length, explaining the pathological processes known as varicose atrophy and chromatolysis. He thought that this mass of observation formed the foundation for a working hypothesis of mind, and if it were objected that the connection between matter and consciousness was unthinkable, a sufficient reply for practical purposes was, that mind could be profoundly affected and morbid states of consciousness produced, by purely chemical means. The clinical and pathological study of insanity, therefore, became incumbent, of which the latter was at present the more promising field.

The first problem encountered by the pathologist was that of the physical states underlying mental pleasure and pain. The states themselves, especially when morbid, were so absolutely different that it was not surprising that attempts at explanation had been made, one of which was the now abandoned theory, that melancholia was due to brain anæmia, and mania to brain hyperæmia. Yet there was here probably some modicum of truth, and he proposed to consider the question afresh. The arrangements for the blood-supply of the cerebral cortex were then gone into, and it was pointed out that the area supposed to be psychically most important, was particularly well furnished in this respect. It appeared from experimental research that the cerebral circulation as a whole was practically at the mercy of the general blood pressure; but there were facts showing that this was not always so, and in any case there might be local variations in different areas of the brain-cortex.

Coming to the problem under discussion, in conditions of brain anæmia there was found as a matter of clinical observation, a group of symptoms which most typically consisted of lethargic depression with morbid suspicion and loss of intelligence, &c. It appeared in more or less perfection in lactational and phthisical insanity, and in cases arising from starvation and indigestion; in chlorosis, pernicious anæmia, and syphilitic anæmia; in mitral valvular disease and emphysema, and in disease of the cerebral vessels. Both acute and chronic anæmia and want of oxygen had been found to produce changes (varicose atrophy and chromatolysis) in the nerve-cells.

In ordinary melancholia, reduction in the amount of hæmoglobin in the blood had been found, which returned to normal on recovery. On the other hand, high arterial pressure was the rule in all states of mental pain, both sane and insane, and appeared to be proportional to the acuteness of the pain, which was relieved by measures which reduced the tension. But this, which seemed to indicate an increased flow through the brain, would only mean this if the venous

pressure remained low, of which there was no proof, and, on the other hand, high blood pressure with slow pulse were symptoms of bulbar anæmia and were found in general anæmic conditions. Moreover, whatever the effect within the cranium, the other organs of the body were rendered anæmic, and thus the blood was poorer both in gaseous and solid nutriment. Cases of depression again, where the mind is excessively active within a very limited range, generally that of the moral sense, might be explained by a localised hyperæmia of the corresponding area of the cortex, with anæmia of all the rest.

Excitement might occur with melancholia (when the blood-pressure was found to be variable), and was common in mental exaltation. It was a condition apart from either, and ought if possible to be eliminated in studying them. When of marked degree it, like the convulsions with which it was so closely related, was a "discharging lesion" due to "irritable weakness" of the nerve cells, and was produced by anæmia of sudden onset or considerable degree. This was shown by the class of cases in which it occurred, and by the results of treatment. As might be expected the blood-pressure in excitement was low.

Mania meant excitement along with, in most instances, exaltation, but the latter symptom predominated in certain classes of cases, in which it could be well studied. It was best, however, not to approach the question from this side, but to inquire first what would be the effect on the nervous system of increased oxygen supply.

Inhalation of oxygen under higher pressures than that of the atmosphere had been found to produce exhilaration, excitement and feverishness, convulsions, indications of mental derangement, and even death, according to the pressure, the period of inhalation, and the species; and appearances like chromatolysis had been seen in the nerve-cells. These results were caused by a mere proportion to the tension of the oxygen in simple solution in the blood. There was, however, no evidence that these conditions could arise otherwise than experimentally, but at the same time it was possible that increase of blood-flow and of hæmoglobin percentage, with, perhaps, other conditions, might slightly raise the oxygen tension of the blood. This was all that could be said, and experimental hyperæmia of the brain had not been found to cause symptoms.

In mania the hæmoglobin was about normal in contrast to melancholia. On the other hand the blood pressure was usually low, but in the absence of evidence as to the venous pressure, no conclusion regarding the cerebral circulation could be drawn from this fact. The general nutrition in the slighter cases of mania was actually improved, and there was not improbably more oxygen in the blood. On the whole the facts seemed to point to a connection, whether causal or not, between increased or enriched blood supply and mental exaltation.

Although fresh observation was needed at every point, the results of the inquiry might be summed up as follows:—

1. The emotional state produced by brain anæmia when gradual in onset, not too profound, and of some duration, is depression.
2. Anæmia of rapid onset and considerable degree tends to produce convulsions and excitement.
3. The characteristic feature of the general circulation in mental depression is high arterial tension, which helps to maintain, if it does not cause the painful mental state; but there is no conclusive evidence of the condition of the cerebral circulation.
4. In mental depression the blood is impoverished.
5. Under experimental conditions high oxygen tension in the blood supplied to the nerve-cells produces excessive action and possibly exhilaration.

(a) Abstract of Inaugural address delivered at the opening meeting of the Dublin University Biological Association, November 28th.

but there is no real evidence that such symptoms are ever due to this cause under ordinary circumstances.

6. The characteristic feature of the general circulation in excitement, and probably in exaltation, is low arterial tension. Here, again, there is no direct evidence of the state of the cerebral circulation.

7. This low arterial tension helps to maintain, if it does not cause, the mental state. The speaker concluded by deprecating a hard material conception of psychology except in the limited sense defined at the beginning of the address, and by urging the importance of psychological observation on the part of the general profession.

THE USE OF ALCOHOLIC BEVERAGES.

FROM THE STANDPOINT OF A MERE PHILOSOPHICAL EPICURE.

By JAMES EDMUNDS, M.D., M.R.C.P.Lond., &c.

THERE is a standpoint to which I think that no sufficient prominence has yet been given as a motive for abstinence from alcoholic beverages. That standpoint is neither social, religious, nor political. It is a purely personal motive, *i.e.*, the motive springing from a conviction that if one would live the highest, best, and most effective life, one must discard narcotics of all kinds. Influenced by that motive, the abstainer makes no pretences of special virtue, he charges no sin against those who use narcotics, he looks on with equanimity, and even with physiological interest, while his friends subject themselves to a course of chronic poisoning. He may amuse himself with Dr. McGee's claptrap phrase, referred to in your leading article on November 22nd, and tell his friends that he would "sooner see them free than sober." When his friends do him the honour to dine with him, he can furnish them with wine and cigars, and do all that is needed to make them comfortable in their own way, one thing only excepted—he does not poison himself with alcohol or tobacco—not even to please his friends. That is what I call the standpoint of the philosophical epicurean—the man who has arrived at the intellectual conviction that the use of alcoholic beverages lowers the level of physical and mental power, lessens the luxury of living, impairs the output and the quality of the work done, and shortens the natural longevity—the man who having arrived at this conviction makes up his mind to live accordingly, and lays down for himself the straight line of total abstinence as more easily worked up to than the crooked line of "moderation" or of occasional indulgence—just to make one's friends comfortable or to avoid being peculiar. What I submit is that, if the philosophical epicurean be not right, there is no bottom for total abstinence, and the sooner it is dropped the better. If the philosophical epicurean be right, there is no need for any other motive. In fact, all other motives must be false and misleading.

What Bishop McGee meant by his phrase I have never been able to make out. Surely a man may be free as well as sober. There is no sort of antagonism between freedom and sobriety. In fact, it is only men who are sober who attain full freedom. Yet this miserable phrase passes for argument. A generation before uttering that phrase McGee took the temperance pledge at a meeting at Bath. He did not keep the pledge, and hence, probably, the pungency of his speech on this point. He must have thought that he was talking sense when he said that he would "sooner see England free than sober." But can anyone point out what the sense is?

If I may descend to my own personal experience would say that I never in my life was perceptibly

under the influence of alcohol, and that in my student days I was, from motives of thrift, practically an abstainer. In my practice I learnt from my old master the rule never to take a glass of wine in a patient's house, and I have never on any occasion varied from that rule. Among patients with whom I might dine, my practice as a guest was the same as with other friends, but on no occasion of professional intercourse did I ever take any alcoholic beverage. If up at night when doing a large midwifery practice I would order tea and toast, or, in special cases, a broiled chop with tea and toast. But, when dining out, for many years I did not like to be peculiar, and I took wine just as other gentlemen might. And at my own lunch or dinner at home a glass of ale or a little wine would generally be taken. During these years I saw no principle in the matter, and simply looked with contempt upon men who used alcohol intemperately. Tobacco I never used in my life in any shape or on any occasion.

In 1864 I was bothered by one of my patients, who was secretary to a teetotal society, to take the chair at a temperance meeting. I had never previously looked upon abstainers as anything but fanatics, and at once declared myself a moderate—a real temperance man. However, I could not get away from my pertinacious patient—a working saddler, who had pleased me as a foreman in some harness work I had needed—and I most reluctantly promised to take the chair for him, although I was then surgeon to the great brewery—Truman, Hanbury, Buxton and Co. It was understood that I did not go as a teetotaler, and that I was to say what I chose. I went. I opened the meeting with an emphatic recommendation of "moderation," and an emphatic disavowal of total abstinence. The temperance meeting listened to me with perfect toleration, and then several working men got up one after another and spoke. They told a tale of misery and suffering, and how teetotalism had rescued them and made them successful and useful in life, and had made their wives and children happy instead of miserable. Every word they said went home to me, and put life into pictures which, in my daily work, I had long seen without seeing. In fact, those working men fastened this question into my mind, and made me feel that, in my opening remarks, I had been flippant and wrong. I closed the meeting in a very different spirit, and I promised to think very carefully over the subject.

The result of what I heard at that meeting raised with me the question of what was right in this matter, and I left off my own little wine and beer. I found at first that water was insipid, and especially at times when I was heavily worked. I got a shade thinner in person; and at first I missed my little daily dose of alcohol. But I soon got used to water, and I found that my quickness and power in work were, if anything, better and more uniform. Beyond a few ounces of alcohol in all—taken during recent years for experimental purposes—I have never since taken any alcoholic beverage. I did a very large general practice for many years, including some 300 midwifery cases a year, and I never allowed an assistant to give ergot or use instruments without sending for me. I believe that I have gained everything and lost nothing by my thirty-five years of total abstinence from alcohol, and by my life abstinence from tobacco. Now, after fifty years' really hard medical work in London—often with a propensity to blow off steam very wastefully, I have perfect senses and still enjoy my work thoroughly. That is my experience, and I am an abstainer, not for any one else's good, but simply for my own good, and as an epicurean philosopher. The rule that I think should be laid down as to becoming an abstainer is that a sound intellectual conviction is the first stage. Habit must then be cultivated.

For every year that a man has drunk moderately he needs a week of total abstinence before the natural conditions of palate and digestion can be recovered, and he is in a position to judge of the effects of the use and disuse of alcohol. One needs to work on the old maxim of Pythagoras, "First find out that course in life which is best, and then habit will soon render it the most delightful." Above all things, no sneaking out of the publichouse into the druggists' shop. No substitutes. If a man wants to drink let him get drunk honestly at a publichouse, not get intoxicated at the druggist's shop.

One word as to the political aspect of the temperance question. I am not sure that there is much in it. But as one who believes in local self-government for local affairs, I would deal with drink shops as local affairs, and leave their maintenance or their suppression to the votes of the people for whose convenience the licences are supposed to be granted. But as to getting an Imperial enactment to suppress the sale of drink, it seems to me at present an illusion. We now have 32 of the leading men in the country constituting our present Government—a Government second to no Government in the world for all round ability and character. Now, of those 32 eminent and leading Britishmen only one is a total abstainer. In the face of such a fact how can we expect to enact a total prohibition of the sale of those drinks which so large a proportion of our leaders honestly believe themselves to require.

The question of using, or of disusing, alcoholic beverages is a question of medical science. It should be taken up and seriously studied by the medical profession. Doctors are the only men who can push this movement on through its next stage, and by so doing they can vastly serve the community. They can also do themselves and their profession honour by advancing the public good.

LACTATION: IN THE VIRGIN— IN THE OLD WOMAN—IN THE ADULT MALE—IN THE NEW-BORN OF EITHER SEX ("WITCHES' MILK").

By JOHN KNOTT, M.A., M.D.,
CH.B., AND DIP. STAT. MED. (Univ. Dub.),
M.R.C.P.I., M.R.I.A.

THE issue of the MEDICAL PRESS AND CIRCULAR for November 22nd, 1899, contains a short comment on "Lactation in a Virgin," for which the "text" was confessedly furnished by a communication made by a physician to *La Médecine Moderne*. The English commentator justly attributes to the case in question "a physiological interest," and proceeds to add: "We remember to have heard of similar occurrences, more or less well authenticated, in non-pregnant females, even of advanced years; indeed, an abundant lacteal secretion has actually been noted in the newly-born, even of the male sex." The general tone of this, the concluding sentence of the article in question, leaves the impression—at least upon the mind of one reader of the MEDICAL PRESS AND CIRCULAR—that the phenomena of the physiological vagaries therein referred to are not quite so well known as I think they should be. Accordingly, I have thought that the gleanings of a few pages of my professional Commonplace Book might not prove uninteresting to a certain proportion, at least, of the readers of this Journal.

To begin with the beginning. The fact of the occasional occurrence of "lactation in a virgin" is mentioned and commented upon by the illustrious

"Father of Medicine" himself; and his observations have been periodically reinforced by new cases in all the ages down to the present period. A very interesting instance is mentioned by the great French obstetrician, Beaulocque,—of a girl of eight years old, who suckled her brother for a month. I have myself been consulted within the past few weeks by the nurse (attendant) of a child—suckled by its mother—who had been greatly distressed by the appearance of an unexpected lacteal secretion. During a comparatively slight indisposition of the nursing mother, the baby had, by my advice, been placed to sleep with the nurse; and the attempts of the latter to keep her troublesome charge in somewhat better order by encouraging its instinctive attentions to the mammary glands had led to the unexpected and unpleasing result. The removal of the stimulus, followed by appropriate treatment, general and local, soon led to the complete disappearance of the abnormal phenomenon.

The distinguished American physiologist, Duglison, observed that "the secretion may arise independently of impregnation; for it has been witnessed in the unquestionable virgin, in the superannuated female, and even in the male sex." Turning our attention now to the "superannuated female," I find that Dr. Gordon Smith refers to a manuscript—one of the rare and interesting collection made by Sir Hans Sloane, in which is recorded the case of a woman, aged sixty-eight, who had not borne a child for more than twenty years before, and who had, nevertheless, nursed all her grandchildren, one after the other. And Professor Hall, of the University of Maryland, related the case of a widow, aged fifty, whom he had actually seen in the act of giving suck to one of her grandchildren, although she had not borne a child of her own for more than twenty years previously. In this instance the secretion of milk had been called forth by trying to quiet the child—during the process of weaning—by putting it to her breast. Dr. Francis, of New York, narrated the case of a lady, who had been delivered of a healthy child, fourteen years before, after a natural labour. He proceeds to observe that "since that period her breasts have regularly secreted milk in great abundance, so that, to use her own language, she could at all times easily perform the office of a nurse." Dr. Kennedy, of Ashby-de-la-Zouch, has described the case of a woman who menstruated during lactation, suckled children uninterruptedly through the full course of forty-seven years; and, in her eighty-first year, had a moderate, but regular supply of milk; and this "rich, and sweet, and not differing from that yielded by young and healthy mothers."

Dr. Stack recorded in the "Philosophical Transactions" the case of an old woman whom he had seen in Tottenham Court Road. She was then aged sixty-four, and had not borne a child for sixteen years. He found her "secreting milk after repeatedly applying her grandchild to her breasts for the purpose of quieting it, and continuing to furnish milk in great abundance up to the time of the publication of the case—an interval of four years—to the children of her daughter, who, finding her mother so useful, 'was emboldened to bid fair for an increase of issue, which, till then, she knew not how to nourish or provide for.'"

Sexual excitement I should guess to be the exciting cause in such cases as the following, mentioned by Dr. Elliotson: "I myself saw two married women with milk in their breasts, one of whom had never been pregnant, but always menstruated regularly, and said this had been the case for nine months; the other had not been pregnant for upwards of six years, had weaned her child, and at the end of seven months miscarried, and said she immediately after

wards observed the milk, which had been secreted for six months and was increasing at the time I saw her."

Ovarian ("reflex") irritation is not unfrequently a cause, and an easily intelligible one, of the abnormal secretion of milk. The following case, also observed by Dr. Elliotson, would, I think, be an example: "I also attended a young single lady, whom I believe never to have been pregnant, but who was subject to amenorrhœa, and had not then menstruated for five months, and laboured, apparently, under ovarian disease; milk oozed very copiously from her breasts, and the medical attendant informed me that the left had secreted it for many months."

From the consideration of the abnormal secretion afforded by the young unimpregnated and the physiologically superannuated female, we may pass to the still more anomalous cases of the establishment of the function in the male.

When a boy, resident in the West of Ireland, and long before I had imbibed the most elementary idea of the meaning of the term "physiology," I heard discussed among some farm labourers the case of a peasant of the preceding generation, who lived near the shore of Lough Gara, and who had been left a widower—with a baby of a few months old. This had occurred in winter; and, in order to supply what care and warmth he could afford, the father took the infant to his own bed. To quiet its restlessness at night, he offered his nipple, with the result, after a time, of the establishment of the lacteal secretion. During the whole of the following spring, while labouring at the planting of his potato crop, he used to "leave his boy" at regular intervals, and go to his cabin to "give the breast" to his infant child.

Professor Hall, of the University of Maryland, exhibited to his obstetrical class, in the year 1827, a coloured man, fifty-five years of age, who had large, soft, well-formed mammae, rather more conical than those of the female, and projecting fully seven inches from the chest; with perfect and large nipples. The glandular structure seemed to the touch to be exactly like that of the female. This man, according to Professor Hall, had officiated as wet-nurse, for several years, in the family of his mistress; and he represented that the secretion of milk was induced by applying the children entrusted to his care to the breast, during the night. When the milk was no longer required, great difficulty was experienced in arresting the secretion. His genital organs were fully developed.

In the "Philosophical Transactions" for 1741 (Vol. XLI., p. 810), we find an Article which bears this title: "A Letter from the Right Revd. Father in God, Robert Lord Bishop of Corke, to the Right Honble. John Earl of Egmont, F.R.S., concerning an Extraordinary Skeleton, and of a Man who gave Suck to a Child." This letter bears date "Corke, Aug. 8, 1738," and after due consideration has been given to the peculiarities of the "Extraordinary Skeleton," the writer proceeds to the following history of the second item of interest:—

"And now that I am engaged in writing I will venture to give an Account of a Man I met at Inishan, about 10 miles from this Place. He was an old Man about 70 years of Age, by Birth a Frenchman, but was a Refugee on account of his Religion, was bred a Gardener, and, by all Accounts, had been industrious till deprived of his Strength by Age.

"He asked me for Charity, and I gave him half-a-crown. I mention this Particular, that the remaining Part of the Story may not seem to be told for the sake of Gain. After I had done this, and was gone into the House, I heard a Noise at the Door. The Man, out of gratitude, had returned to show me a Curiosity, which was that of his Breasts, with which he affirmed he had once suckled a Child of his own:

His wife, he said, died when the Child was about Two Months old: the Child crying exceedingly while it was in bed with him, he gave it his Breast to suck, only with an Expectation to keep it quiet; but, behold, he found that the Child in time extracted Milk; and he affirmed that he had Milk enough afterwards to rear the Child. I looked at his Breasts, which were then very large for a Man; but the Nipple was as large or larger than any Woman's I ever saw. Some Ladies were then passing by; so I sent him off in Haste, and have not seen him since.

"I have either heard or read of one Instance of this kind before."

In Franklin's "Journey to the Shores of the Polar Sea," the author gives an interesting case as an instance of the unconquerable parental affection of the untutored Chipewyan. Passing from other subjects to this, he alludes to the striking example of which he had recently obtained evidence:—"I shall venture to give it in the words of Dr. Richardson's Journal. 'A young Chipewyan had separated from the rest of his band for the purpose of trenching beaver, when his wife, who was his sole companion, and in her first pregnancy, was seized with the pains of labour. She died on the third day after she had given birth to a boy. The husband was inconsolable, and vowed in his anguish never to take another woman to wife, but his grief was soon in some degree absorbed in anxiety for the fate of his infant son. To preserve its life he descended to the office of nurse, so degrading in the eyes of a Chipewyan, as partaking of the duties of a woman. He swaddled it in soft moss, fed it with broth made from the flesh of the deer, and to still its cries applied it to his breast, praying earnestly to the Great Master of Life, to assist his endeavours. The force of the powerful passion by which he was actuated produced the same effect in his case as it has done in some others which are recorded; a flow of milk actually took place from his breast. He succeeded in rearing his child, taught him to be a hunter, and when he attained the age of manhood, chose him a wife from the tribe. The old man kept his vow in never taking a second wife himself, but he delighted in tending his son's children, and when his daughter-in-law used to interfere, saying, that it was not the occupation of a man, he was wont to reply that he had promised to the great Master of Life, if his child was spared, never to be proud, like the other Indians. He used to mention, too, as a certain proof of the approbation of Providence, that although he was always obliged to carry his child on his back while hunting, yet that it never roused a moose by its cries, being always particularly still at those times. Our informant [Mr. Wentzel] added that he had often seen this Indian in his old age, and that his left breast, even then, retained the unusual size, it had acquired in his occupation of nurse."

It is stated, on what appears to be good authority, that this occurrence of the lacteal secretion in the adult male is, or was, common in Russia. ("Comment. Acad. Sc. Petropolit," Vol. III., p. 278.) I regret that I have no later reference on the subject.

With regard to the general question of the occurrence of a mammary secretion in the male mammal, Blumenbach published some curious items of information. One case is that of a he-goat, which its owner found necessary to milk on every alternate day throughout a whole year. Commenting on this case, Dr. Elliotson wittily observes, "so that, to say with Virgil, *mulgeat hircos* is not tantamount to calling a man a fool. In the "Philosophical Transactions" (1799), there is a case recorded of a bull which had been put to cows successfully, and had also rudimentary female organs of generation. According to "satisfactory testimony," this animal gave milk. There is also a case given in the "Philosophical Trans-

actions" of a lamb, the property of a Sir William Lowther, which had lost its dam, and then commenced to suck a wether that grazed in its company. The effect of the efforts of the orphan lamb was that it "brought him to milk, and was maintained by him all the summer: he had two considerable teats on his udder, each side whereof was about the bigness of a hen's egg." After the lamb had been weaned for a whole month the milk could be made spurt to a distance of two yards.

(To be concluded in our next.)

Clinical Records.

DEATH FROM ELECTRIC SHOCK.

By Mr. PERCY G. LODGE, L.S.A.,
Bradford.

At the works of Messrs. J. Holden and Sons, Bradford, on November 20th, E— D—, *æt.* 29, of Bradford, whilst repairing a lamp, slipped off the hand-steps on which he was standing, and to save himself caught at the insulated wires. Eye-witnesses state that his whole body became violently flexed, his grasp fixed, and he finally fell. When picked up he was dead.

Dr. S. Lodge, the police surgeon, made a post-mortem examination on the following Thursday at which I assisted. The medical officer of health, Dr. Evans, also assisted in the proceedings, and Dr. Campbell, of the Bradford Infirmary, was present.

Post-mortem (14 hours).—Externally: Body was not quite cold. There was a superficial redness over the axillæ and flanks. The eyes were bright, and there was none of the haziness usually seen after death about the corneæ. The pupils were dilated equally. No bruises were to be seen, the hair on the inner and outer sides of the knees was white and frizzled, as though scorched or bleached. The hands, especially the right, were firmly flexed. Internally: On opening the head, there was a bruise beneath the scalp on the right parietal region as large as a florin, with a few corresponding ecchymoses on the pia mater more deeply. The brain weighed forty-eight ounces. It was firm and healthy. There was no sign of any fracture of the skull. On opening up the trunk free venous hæmorrhage was observed from the incision, and the blood exhibited a marked fluidity. The lungs were both healthy. The heart was empty and free from valvular or other lesion. The pericardium contained a small quantity of clear fluid. A small bruise like an ecchymosis was seen beneath the visceral pericardial endothelium over the ventricle. This was quite superficial. The ventricular walls were firm and of normal thickness. The liver was quite healthy, weight $3\frac{1}{2}$ lbs. The kidneys were firm and healthy. Right weighed $4\frac{1}{2}$ ozs., left $4\frac{1}{2}$ ozs. Spleen normal. Dr. S. Lodge states that the body was that of an exceeding healthy individual, well nourished and muscular. He was about 5 ft. in height and about 10 st. in weight. The increasing frequency of death from electric shock and the rarity of published reports of post-mortem appearances induce me to present these necessarily brief notes. The most marked features in the post-mortem appearances are, the fluidity of the blood and the absence of any form of physical lesions.

Transactions of Societies.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

At a meeting held on December 1st, the President, Dr. J. B. BALL, made the following proposal:—That it is desirable that this Society should join in the scheme, in connection with the

SOLDIERS' AND SAILORS' FAMILIES' ASSOCIATION, to afford gratuitous medical attendance in their own homes for the necessitous wives and families of soldiers and sailors now serving with the colours. And that a sub-committee be formed to carry out this resolution. The proposal was carried unanimously. Mr. C. B.

Keetley proposed that the following should be nominated members of the sub-committee to carry into effect the resolution which had just been passed by the Society. The President (Dr. J. B. Ball), the secretaries (Drs. G. D. Robinson and G. P. Shuter), the treasurer (Mr. Gunton Atherton), Mr. F. Lawrance, Mr. W. H. C. Staveley, Dr. S. D. Clippingdale, Dr. A. H. W. Clemon, and Dr. H. Campbell Pope, with power to add to their number.

Dr. W. H. Waller seconded the motion, which was carried unanimously.

CASES EXHIBITED.

Mr. McADAM ECCLES then showed a case of Excision of Carcinoma of the ascending colon in a woman, *æt.* 45. The patient was operated on for cystic right ovary which was removed. On further examination the whole circumference of the ascending colon was found to be involved by a large growth. The diseased portion of the gut was brought to the surface and stitched to the skin. Eight days afterwards the tumour was removed with complete success, the woman making a good recovery. No secondary deposits were found at the time, and there had been no recurrence since.

Remarks were made by the President, Messrs. L. A. Bidwell, C. B. Keetley, and E. P. Paton.

Dr. GEORGE JOHNSON showed a case of intra-cranial growth affecting the first eight cranial nerves in a sister of the last patient. After minutely describing and demonstrating the patient's symptoms, Dr. Johnson said that the lesion was improving under treatment, and that it was probably of a syphilitic character. Dr. Seymour Taylor showed a patient who was suffering from injuries to nerves due to a fall of a few feet. On one side the seventh and eighth were affected and on the opposite side the eighth nerve alone. The cases were discussed by the President, Messrs. McAdam Eccles and E. P. Paton.

Mr. L. A. BIDWELL showed two sisters from whom thyroid cysts had been removed. Also a case of congenital syphilitic synovitis of both knees. The three cases were discussed by Messrs. W. H. C. Staveley and W. McAdam Eccles.

Mr. McADAM ECCLES showed a case of wiring in an ununited fracture of the tibia, with skiagraphs by Dr. F. H. Low.

Mr. C. B. KEETLEY showed a patient on whom he had operated for extensive suppuration of the abdominal wall, and who had attended the West London Hospital for an offensive purulent discharge from the vagina. An incision was made in the middle line, a large quantity of pus and air being evacuated. Another incision was made to the right of the umbilicus, on passing the finger through this opening into the pelvis the cervix could easily be felt; but the body of the uterus had disappeared. He diagnosed the case as one of pelvic suppuration, the pus having tracked up into the abdominal wall. Remarks were made by Dr. G. D. Robinson.

Dr. G. D. ROBINSON showed two skin cases for Dr. P. Abraham. (1) Case of Condylomata about the anus in an infant, *æt.* 1. There was no history of syphilis maternal or otherwise, and the child was rapidly cured by the external application of zinc oxide and calomel; (2) Case of pityriasis rosea of Gibert showing points of resemblance to linea circinata as well as to eczema seborrhoicum.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD NOVEMBER 27TH, 1899.

The President, Dr. BURGESS, in the Chair.

Mr. EDWARD SKINNER showed an instrument for examining throats of cases suffering from diphtheria, consisting of spoon handle, having a glass disc between the observer and patient.

Dr. ARTHUR HALL showed the following cases:—(1) A young woman with very loud rough aortic systolic murmur of some years' duration, in whom a diastolic murmur has developed during the last month or two. There is no history of rheumatism, strain, or syphilis. Up to the present time the obstruction has not caused

any ventricular dilatation or hypertrophy. (2) A girl with keratosis palmaris et plantaris. (3) A man with multiple soft fibromata varying in size from a pin's head up to a marble. Not pedunculated. (4) A case of favus of the cheek in a child (photograph).

Dr. GWYNNE showed a case of

PSEUDO-HYPERTROPHIC PARALYSIS.

The patient a boy, *et. 6½*, began to develop the disease about 2½ years ago. Two of his maternal uncles suffered from paralysis in early life. There was no mental deficiency. He was unable to walk, and could not rise from the stooping posture without the aid of his hands. The muscles of the calves were enlarged and hard, as were also the erector spinae muscles and the infra spinati. Most of the muscles of the upper extremity were atrophied, also the muscles of the chest and ribs. The Faradic current produced no reaction except slightly in flexor longus pollicis and the adductor pollicis brevis. The galvanic current (16 cells) produced no reaction in the lower limbs except in the tendo-achillis. Most of the muscles of the upper limb were unaffected by the current including the supra spinatus and infra spinatus. The adductor pollicis brevis and the flexor communis digitorum in the right side showed the R.D. reaction. He favoured the view that the disease was a primary idiopathic atrophy of the muscles.

Dr. ROBERTSON gave a demonstration on organisms isolated from the throats of children attending public elementary schools during the prevalence of diphtheria, and contrasted these with typical diphtheria bacilli. He afterwards read a paper on "Some Points in the Etiology of Diphtheria," in which he dwelt at length on the number of children attending school—apparently in good health, who had in their throats either typical diphtheria bacilli or organisms which could not by microscopical method be distinguished from them. Examination had shown that in schools not attacked with diphtheria the children did not in any instance show the diphtheria bacillus in the throat. During the past twelve months fifty-nine selected children from five schools had been examined bacteriologically—of these seventeen showed typical diphtheria bacilli, thirteen showed an organism very like the bacillus diphtheriae, while the remaining nineteen gave no suspicious organism. All of these children were at school when examined, and none of them had any typical diphtheritic lesions.

Dr. ROBERTSON gave it as his opinion that the occurrence of such unrecognised cases was one of the most important difficulties in dealing with epidemic diphtheria, and unless they were recognised other preventive measures were likely to be abortive.

Dr. ANDERSON read a paper on

THE SERUM TREATMENT OF DIPHTHERIA.

He gave a brief resumé of the results obtained by the use of antitoxin in different parts of the world, pointing out that, though generally there had been a reduction in the total case-mortality by about one-half, the best results were obtained where treatment was commenced within the first three days of the onset. In a series of 258 consecutive cases treated by antitoxin at the City Hospital, Sheffield, where 46 per cent. of the cases were admitted on the fifth day and after, the case-mortality was 15.8 per cent. In Chicago the mortality in 4,071 cases, only 11 per cent., and of those which were treated on the fifth day and after it, was only 6.77 per cent. Early administration was the most important point. It was not advisable to waste too much time in disinfecting the skin, and it was bad practice to wait for the results of a bacteriological examination before using antitoxin. The enormous reduction in the mortality of post-scarlatinal diphtheria was due to the fact that all such cases were injected on the first or second day. In laryngeal diphtheria, if antitoxin treatment was begun early enough, operative interference was often unnecessary. Intubation ought to be given a trial as the primary operation in most cases. He had never observed any really serious constitutional disturbances following the injections, though in a few cases the occurrence of pains in the joints in patients suffering from cardio-gastric symptoms seemed to accentuate the tendency to collapse. Antitoxin albu-

minuria was of no real importance. The dose in a mild case should be 4,000 units. In severe cases the best plan was to give 4,000 units every three hours for three or four doses and to repeat similarly next day if necessary. In his experience this was better than giving one or two large doses of 8,000 or 12,000 units. Septic complications were very infrequent in diphtheria. The associated micrococci seemed harmless enough, though they had all the advantages of the situation. Where cervical cellulitis was present, he had tried simultaneous injections of antitoxin and anti-streptococcic serum, but with no better results than with antitoxin alone. A perfected serum would no doubt be obtained with a greater affinity for the toxins and a diminished liability to the production of rashes and pains, which were often a source of considerable annoyance and discomfort.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD NOVEMBER 21st, 1899.

The President, Mr. W. HORROCKS, in the Chair.

Dr. EURICH gave an exhibition of pathological specimens, among them was (1) a specimen of angio-sarcoma of kidney, (2) primary melanotic sarcoma of spinal column which invaded the dura mater and destroyed the spinal cord by pressure. There was no metastasis except in the lungs. The specimen was spoken of as one of extreme rarity.

Mr. J. B. HALL showed a popliteal aneurism, the result of a comminuted fracture into the knee-joint.

Dr. RABAGLIATI read notes on a case of

SUPPURATIVE PELVIC CELLULITIS,

And made some general remarks on the sequence of high and low temperatures in inflammatory diseases. We hope to publish a full report of this case in an early number.

Dr. JOHNSTONE CAMPBELL related a case of

ADDISON'S DISEASE,

And showed the diseased suprarenal bodies obtained post-mortem. The patient was a man, *et. 48*, a shoemaker. Nine months prior to admission the illness had commenced with nausea and vomiting in the morning. His appetite failed, and bronzing of the skin soon began to show itself. The fingers and toes became blue in the cold weather. On examination the patient showed well marked "bronzing" of skin, especially in the folds and over the points of pressure, *e.g.*, at the place where a truss was applied. The skin over the terminal phalanges of fingers and toes was cold and blue, although the weather was warm. Urine normal. The heart was normal. No sign of tubercle in the lungs. Examination of abdomen negative. The pulse was small and feeble, and the patient very weak. The appetite was bad, and he vomited occasionally. Patient rapidly got weaker, refused to take his food, and, passing into a semi-unconscious state, died on June 19th, 1897, seventeen days after admission. Post-mortem examination showed extensive tuberculous disease of the suprarenal bodies.

Dr. CAMPBELL remarked that the case showed the typical symptoms of the disease. The asthenia without marked wasting, the pigmentation, the persistent nausea and low blood pressure rendered the diagnosis easy, and it was confirmed by the post-mortem appearances. After discussing the history of the disease, and the experimental work in connection with the suprarenal bodies. Dr. Campbell expressed the opinion that there was a hope of good result in the future from the treatment by suprarenal extract. He remarked that intravenous injection was the ideal method of administration, but was not available for prolonged treatment. He suggested the employment of suppositories, made up with a neutral fat.

Dr. KERR showed a patient who had "Embolism of Central Artery of the Retina," and who had since been found to have kidney trouble, and who thirty hours previously had blindness in the left eye, a small patch of the field from the fixation point down and out being preserved. The fundus presented the typical picture of embolism of the central artery. In two of the vessels,

which appeared to be veins, broken up blood columns were seen slowly progressing, with pulsating movements in one case towards, in the other from, the nerve head.

TRAUMATIC HYSTERICAL MONOCULAR DEVIATION.

Dr. KEER read notes of the case, and presented a single spare woman, who, as result of a knock on the cheek ten years previously, had deviation of the eyeball 30 degs. up, and 27 degs. out. Several operations—advancement of both internal and inferior, and tenotomy of external and superior recti and of inferior oblique, had restored her appearance, the deviation with the Maddox test being now 2 degs. out and 6 degs. up. There was accommodative asthenopia, contracted field of vision, and pharyngeal anaesthesia, and after a full discussion of the features of the case, the diagnosis of traumatic hysterical contracture was arrived at as affording the best explanation.

LIVERPOOL MEDICAL SOCIETY.

MEETING HELD THURSDAY, NOVEMBER 16TH, 1899.

Dr. MACFIE CAMPBELL, President, in the Chair.

Mr. FRANK T. PAUL related two cases of colectomy.

Mr. RUSHTON PARKER related a case of gastric ulcer in which perforation occurred, necessitating an operation.

Mr. PAUL related a case of

PERFORATING GASTRIC ULCER IN WHICH THE EXTRAVASATION BECAME LOCALISED, AND THE PATIENT RECOVERED WITHOUT OPERATION.

For three weeks not a drop of anything was swallowed, and the deprivation was borne without discomfort owing to plenty of water being injected per rectum. He thought that as in appendicitis the different degrees of peritoneal infection called for different treatment.

Mr. THELWALL THOMAS confirmed the previous speaker in the value of injections of water or saline solution into the rectum for shock or after operation for perforated gastric ulcer to diminish thirst. He alluded to two cases (one fatal), in which he had operated, in one case the perforation occurred when the stomach was empty of food, yet the whole peritoneum was soiled, the ulcer being near the pylorus. The other case, which was followed by recovery, the perforation was near the cardiac extremity of the organ, and occurred when the stomach was full, yet the extravasation was limited by the anterior surface of the great omentum. In the first case abdominal lavage was practised, in the second merely wiping out the extravasated food and lymph.

Dr. CANTER remarked on the apparent frequency with which, after immediately successful operations for perforating gastric ulcer death resulted from changes in secondary exudations between the liver or the diaphragm and the stomach. Such, he gathered, was the case in two instances alluded to by speakers this evening, and such was certainly the cause of death in a very difficult, and what for some time promised to be a very successful, operation performed by his colleague, Mr. Robert Jones, some months ago at the Royal Southern Hospital. The patient, a young woman, rallied well, and continued well for some ten days, when a tumour which had formed and presented near the epigastrium, was opened by Dr. Alexander, in Mr. Jones's absence from Liverpool, and gave exit to more than a pint of very fetid pus. She rallied during the operation in a most remarkable manner from what looked like a very moribund condition, the result, apparently, of a free intravenous injection of a warm saline solution, but succumbed a day or two later. As to the possibility of recovery, even without operation after the perforation, he had no doubt whatever, first, because he had seen patients recover where the symptoms left no doubt that such perforation had occurred, and secondly, because in one instance a post-mortem examination years after such an occurrence proved it to have taken place. This case was that of a girl who died of caecal disease and obstruction. She gave a distinct history of a stomach complaint with hæmatemesis. Severe pain and collapse some years before in which her life had been almost despaired of. Post-mortem: we

found extensive firm adhesions between the liver and stomach, with a somewhat cicatricial puckering which convinced us that perforation had taken place, and that nature had successfully sealed the orifice. In other cases even where art has achieved this result, subsequent inflammatory changes at the site of operation may as we have heard to-night cause death.

Drs. Abram and Grunbaum also spoke.

Dr. BRIGGS read a paper on vaginal enucleation and vaginal hysterectomy in the treatment of uterine fibroids (not including polypi). The paper was based mainly upon his own experience in 89 cases treated by the vaginal route, 25 by hysterectomy, and 14 by enucleation. The fibroids enucleated varied in weight from 2 ozs. to 2 lbs. 15 ozs. The uterus and fibroids treated by vaginal hysterectomy varied in weight from 7 ozs. to 2 lbs. 2½ ozs.

The main object of the paper was to show the advantage of an anterior vertical mesial section of the dilated cervix, after separating the bladder as in vaginal hysterectomy, in affording room for piecemeal extraction and enucleation. Enucleation of submucous and interstitial growths was, in his opinion, now rendered as safe as hysterectomy, by the vaginal route. All the thirty-nine patients recovered, and only one operation (enucleation) was followed by a complication (cellulitis) during recovery. In only one case was the enucleation abandoned and hysterectomy substituted. The author alleged this circumstance was some proof as to how far the adaptability of the operation could be gauged by uterine exploration, before enucleation was commenced, and, if need be, total uterine extirpation could follow. Opponents of enucleation on account of fibroids being multiple seem to have overlooked the complete exploration possible at the close of enucleation. One patient had eight growths enucleated in March, 1893, and was now still free from symptoms or physical signs of fibroids.

The work was in all respects less formidable than the work of Pean, but it demonstrated that operative treatment by enucleation by the vaginal route had wider limits than had been generally recognised. The weights of the tumours removed in the author's practice were net weights, minus blood and serum, yet were larger than many which had been treated with greater risk by abdominal hysterectomy.

Dr. GRIMSDALE thought that there was much to be done by vaginal enucleation, but considered that the great difficulty in the application of the operation was the fact that fibroid tumours, being usually multiple, the exact relations of all the tumours were often impossible to make out, so that the operation must often be completed by means of a vaginal hysterectomy. He related a case where he had removed fifteen fibroids by vaginal enucleation with the best result, but it was still possible that other tumours had been left behind, and that a second operation might be required at some future date. For large tumours he preferred to perform abdominal hysterectomy.

The President and Dr. Burton also spoke.

GENERAL MEDICAL COUNCIL

OF

EDUCATION AND REGISTRATION.

WINTER SESSION, 1899.

Sir WILLIAM TURNER, President, in the Chair.

FIRST DAY.—TUESDAY, NOVEMBER 28TH, 1899.

THE Sixty-Eighth Session of the Council was inaugurated on Tuesday of last week by the usual Presidential Address. The PRESIDENT informed the Council that the services of three experts had been obtained to read and report upon the papers which the majority of the Examining Boards had placed at the disposal of the Council in view of steps being taken to raise the standard of the entrance examination to the medical profession.

Alluding to a correspondence which had passed be-

tween himself and the Registrar-General on the subject of the reform of death registration the President remarked that this official could not himself initiate legislation, the matter resting with the Local Government Board. The President added that the Council should not relax its efforts to obtain this much needed reform and should pass a formal resolution on the subject.

With regard to the proposal to obtain further powers from Parliament for strengthening the penal and disciplinary powers possessed by the Council, the President related the steps that had been taken to bring the various degree and diploma-granting bodies into accord, and this object had been attained. He pointed out that it lay with the Council to request the Privy Council either to introduce or, if introduced by a private member, to support, a Bill to carry out this much-needed reform, adding that a motion to that effect would be placed before them.

The further steps taken to secure the identification of persons applying to be admitted to the Medical and Dental Registers were mentioned, and it was promised that the draft report of the Personation Committee would come up for discussion in due course.

A request having been received from the German Ambassador for information on several points regarding the admission of foreigners to the practice of medicine in this country, and as to the conditions under which foreigners can be admitted to examination by the medical authorities in this country, a *précis* had been prepared which had been handed to the Education Committee for their consideration, and this, when adopted by the Council, would be forwarded to the German Government through the usual channels.

With regard to the agitation in Italy in favour of restricting the practice of medicine in that country to persons with native qualifications, the President said he had been requested to ask the Council to move the Government to consult the Law Officers of the Crown in order to obtain an official statement of the rights to practise in this country enjoyed by Italian practitioners. A statement has been prepared by Mr. Muir Mackenzie on the law with respect to the rights of foreign practitioners to practise in the United Kingdom, and a report on the question of reciprocity by the Executive Committee would be brought before the Council.

The Society of Apothecaries had written, challenging the decision of the Queen's Bench Division in the Hunter case, and suggesting that a test case should be arranged with the co-operation of the Council, to be tried in the Court of Appeal, each party to pay its own costs. The address concluded with an allusion to the penal cases and other matters to come before the Council, and after the usual vote of thanks the Council proceeded to the first item of business on the programme.

EXAMINATIONS FOR THE SERVICES.

On the tables of results of the examinations for posts in the Royal Army Medical Service Corps and the Indian Medical Service being brought forward Mr. GEORGE BROWN pointed out that of six candidates from the Irish schools only three had been successful, and he suggested that the reports in question should be referred to the Education or the Examination Committee for consideration.

Sir DYCE DUCKWORTH observed that as chairman of the Education Committee he would not know what to do with the reports if they came before him, and Dr. MACALISTER pointed out that the candidates in question appeared under the heading "qualified but unsuccessful," which merely indicated that they did not come high enough up on the list.

Sir CHRISTOPHER NIXON thought Mr. Brown had discovered a "mare's nest," and he failed to see what good could come from such a reference.

Dr. ATHILL pointed out that the Army Medical Department expected something above a mere "pass" standard, and he suggested that Irish candidates were placed at a disadvantage in being examined by English and Scotch examiners, whose methods were different.

Dr. MCVAIL thought these examinations afforded a means otherwise unobtainable of ascertaining how the

various bodies did their work. He thought, too, the motion was of the nature of a compliment to the departments.

Dr. BRUCE thought it was a question worth looking into, but Sir RICHARD THORNE thought the Council had enough work to do without going out of its way to seek additional subjects.

Dr. LITTLE agreed with Dr. Athill that the Services were not popular in Ireland, and he urged that the motion should take the form of an instruction to the Committee to ascertain the circumstances which led to the unusual success which attended the efforts of the Irish graduates in the more wealthy and appreciative English communities, a proposal which Mr. Brown repudiated.

After some further discussion, the motion was negatived.

THE APOTHECARIES' SOCIETY OF LONDON.

An opportunity was afforded Mr. BRUDENELL CARTER of replying to certain statements made by a member of the Council bearing on the constitution of the Society of Apothecaries and the action of its representative on the Council. He commenced by observing that his conduct and opinions had for some years past been adversely criticised by Mr. Victor Horsley, such criticisms not always being based on facts. He had thought his fifty years' experience of medical practice, his life, his acts, and his writings were sufficient to defend him against these criticisms, but he now felt compelled to protest against certain acts attributed to him in connection with the case of the late Mr. Hunter, in deference to the instructions of the Society he represented. Referring in particular to Mr. Horsley's statement that the Master and Wardens "knew no more about medicine than boot-making," and were really a handful of tradesmen who "without any medical education, notoriously prescribed over the counter in the druggists' shop on the ground floor of the Apothecaries' Hall in Blackfriars," and to the reference elsewhere to himself as "a man who is sent there (to the Council) by a handful of City grocers . . . and who speaks as though he were the representative of a large body of medical men throughout the United Kingdom, instead of the members of the Apothecaries' Society," Mr. Carter remarked that in Mr. Horsley's statements there was a singular "economy of truth," indeed, there was not a particle of truth in the statements. He (Mr. Carter) was not elected by the Master and Wardens but by the Court, a body of twenty-four, of whom the Master and Wardens were three. He commented on the studied insolence of Mr. Horsley's phraseology, and opined that the use of such phraseology addressed to gentlemen of mature years and unblemished character might be compared to the peculiar howl or cry of the variety of the human race known to modern sociologists as the "bounder." He pointed out that since 1815, no one, who was not a medical man, was eligible for election to the court, adding that the Society was mostly composed of medical men. Alluding to a further statement of Mr. Horsley's that the Court of Assistants of the Society contained several gentlemen who were not on the *Medical Register*, he pointed out that this remark referred to a few gentlemen who, having retired from active service, had not placed their names on the *Register* though they happened to be Fellows or members of various colleges. Passing on to the statements made concerning him in respect of the Hunter case, he pointed out that although he happened to have taken the chair at the particular meeting of the committee, he was not the chairman of the committee. At the subsequent meeting of the committee, he believed they only had before them the charge made against Mr. Hunter by Mr. Syme, and they merely had a verbal report that the solicitor "had taken steps to carry out the instructions of the Council." He said that, personally, he knew nothing about the Hunter case, and had incurred no more responsibility than any other member of the Council. In reference to the statement that he had opposed Mr. Horsley having access to the Council's papers, he admitted that he was of opinion that such access should be regulated, and he had voted for this modified access. He complained that while the medical

journals gave publicity to statements adverse to him they suppressed his replies, and he appealed to the journals, if they published the attack, to be fair enough to publish the reply. He denied the right of journalists to comment upon a speech, no report of which appeared in their columns.

Mr. VICTOR HORSLEY having obtained permission to reply, apologised to the Society of Apothecaries for having inadvertently misrepresented their constitution. He had been informed at the office of the Society that practically the representative was elected by the Master and Wardens, and he was also informed that these gentlemen were not on the *Register*. He admitted that when he stated that certain of the members were not on the *Register* he was unaware of the fact that, though not on the *Register*, they were qualified to be there, and he tendered an apology to them in so far as he had maligned them. He reiterated his view that Mr. Carter was not really the representative of the Society seeing that the licentiates had no voice in the matter. He would not concede either that the work of the Society had, as asserted by Mr. Carter, been carried on without reproach. The reputation of the examination of the Society among students bore him out in the views he had expressed on the Apothecaries Society as a whole. He failed to see what inaccuracy there was in describing Mr. Carter as chairman of the meeting of the Penal Cases Committee referred to (Mr. CARTER pointed out that Mr. Horsley had not said chairman of the meeting, but chairman of the committee). Mr. HORSLEY, continuing, said he would not quibble over such a little point. Mr. Carter complained that he had been blamed for not observing that Mr. Hunter was an L.S.A., but he (Mr. Carter) had had it before him in print, and he asked whether any of them would have voted for the prosecution of Mr. Hunter among a band of quacks if they had been cognisant of that fact. He maintained everything he had said about Mr. Carter on that point, and declined either to withdraw his statements or to apologise therefor. He concluded by remarking that he had certainly been misinformed as to the nature of the present Court of Assistants, and he apologised for what he had said concerning that body.

The President then declared the incident closed.

DEATH CERTIFICATION.

Mr. Carter moved on behalf of the Executive Committee that the President should request the President of the Local Government Board to receive a deputation from the Council to urge the advisability of early legislation on this subject on the lines of the recommendations of the Committee on Death Certification approved in September, 1893.

This was seconded by Dr. GLOVER, and the PRESIDENT stated that according to one of the latest reports of the Registrar-General for Scotland showed 3·6 of the deaths to have been uncertified, and he thought it not unlikely that in England the proportion was even higher.

Mr. G. BROWN observed that in many cases the registrars of deaths were chemists who had been in attendance on the patients whose deaths they had to certify, and he urged that no chemist should hold such appointments, especially if he prescribed for patients.

The resolution was passed, the selection of the deputation being left in the hands of the President.

ILLEGAL CERTIFICATES.

On the motion of Mr. BROWN, seconded by Dr. GLOVER, a communication from the Yorkshire Branch of the British Medical Association, accompanied by copy of a resolution expressing disapproval of "unauthorised societies or other organisations of registered medical practitioners arrogating to themselves the right to grant diplomas or certificates of proficiency in any branch of medicine, surgery or midwifery," as being contrary to the Medical Acts, was received. A similar communication was received from the East York and North Lincoln branch.

Mr. BROWN had given notice of a motion to rescind the resolution of the Council of May 29th, 1895, relating to the Obstetrical Society's certificates, but the con-

sideration of the motion was postponed in order that its terms might be made conformable to the Standing Orders.

The Council then adjourned.

SECOND DAY—WEDNESDAY, NOVEMBER 29TH, 1899.

CERTIFICATES OF PROFICIENCY IN MIDWIFERY.

Mr. GEORGE BROWN moved resolutions (a) that the President be requested to inform the Obstetrical Society of London, the resolution of May, 1895 notwithstanding, that the Council can no longer assent to the holding of examinations in midwifery, or granting of certificates of proficiency therein by any body of persons, unless invested with legal authority therefore, and (b) that notices be inserted in the leading medical journals to the effect that after January 1st next any registered practitioner who took part in such examinations . . . would be liable to be adjudged guilty of "infamous conduct in a professional respect," and to have his or her name removed from the *Medical Register*. Mr. BROWN referred to the numerous petitions that had been brought before Council in respect of the practice complained of, and he added that not only midwifery was examined in, but also massage, ophthalmic work, &c. He referred to the terms of the Act of 1886, which defined what was a qualifying examination, yet certain societies issued diplomas quite outside that Act. He animadverted on the practice of the Obstetrical Society in granting these certificates, observing that if the Obstetrical Society were permitted to do this sort of thing it was open to anyone so to do.

The PRESIDENT pointed out that the certificate expressly stated that it was not a qualification under the *Medical Act*.

Mr. BROWN admitted that such was the case, and said he would not object to this or any other society issuing a certificate that a person was qualified to act as midwife or monthly nurse. The holder of such a certificate might say that she had a certificate which was approved by the General Medical Council, and this was objectionable.

Mr. VICTOR HORSLEY seconded the motion on two grounds, first that the Council as a whole had never had any opportunity of finally expressing its opinion on the subject, and he hoped that the Council would now acquit themselves of appearing in any way to sanction this certificate. His second point was, that though they must have every sympathy with the Obstetrical Society in taking up these examinations, still he thought the Society was mistaken in issuing any such certificate, the original objection applying equally to the amended certificate.

Dr. GLOVER sympathised with the motion, but urged that it would place the Council in an awkward position to have to stamp men like Sir John Williams as guilty of infamous conduct. The position of the Council was that they had never sanctioned the certificate, and they were all agreed that it was objectionable. It was objectionable also that the Council should appear to give its sanction to an examination which had no legal standing, and he thought they would be doing no harm in withdrawing the apparent sanction which it was said had been given by the Council.

Sir RICHARD THORNE said the fault, if any, of having changed the word "midwife" into "midwifery" and of knocking out the words "natural labour" was that of the Council and not of the Obstetrical Society. He had gone over the resolutions of the Council, and had found that they distinctly urged that midwives should be certified. He urged that after having for twenty years pressed upon the Government the necessity of having midwives certified they could hardly now fall foul of the only body that had made the slightest attempt to achieve what was aimed at. They might as well try to stop the tide at the Nore as to try to do away with the midwife and call her nurse. He thought it was unworthy of the medical profession to say that no women should go through a perfectly physiological process without paying a doctor's fee. If the Council withdrew its assent the Obstetrical Society could go on just the same, and he hoped it would.

Dr. ATTHILL said the greater part of his life was occupied in teaching midwives and sending them out to the public under a special charter. He had always advocated the education of these women as midwives, and midwifery nurses.

Dr. MACALISTER pointed out that if Mr. Brown withdrew his second motion the effect of the first would be just the same. If they withdrew their consent to the second certificate, that would be tantamount to declaring that it was a colourable imitation of a diploma, and exposing those who granted it to be brought under the ban of infamous conduct. He hoped the Council would be careful what they did in this direction.

Dr. LITTLE thought it would be injudicious for the Council to adopt the motion. He pointed out that the Society gave these nurses no legal status.

Sir CHRISTOPHER NIXON urged that the Council ought to do all in its power to secure the holding of an examination of the efficiency of women who practised midwifery, and he thought it would place the Council in a false position to ask the Obstetrical Society to abstain from holding their examinations, though he felt that the Council should be opposed to the granting of a certificate, which was practically used as a diploma.

Dr. LEECH said he would have been pleased to support any resolution to prevent these certificates being granted, but he did not care to go so far as to say that no examinations should be held.

Dr. BRUCE then handed in an amendment to the effect that it was inexpedient under existing circumstances to disturb the present system of examination and granting of certificates to midwives.

Dr. MCVAIL did not like the wording of the resolution, but he preferred it to the amendment. That the system had existed for twenty years was beside the mark. He pointed out that formerly midwifery was held as being much inferior to medicine and surgery, but in 1886 the three branches were placed on the same level, and he hoped they were never going to hear again of the general practitioner regarding midwifery as something alien to his ordinary work.

After some further remarks Sir RICHARD THORNE moved "the previous question," which was carried by fifteen voices to eight. This disposed of the amendment, whereupon Sir C. NIXON, with the consent of Mr. Brown, suggested that the motion should read as follows:—"That the Obstetrical Society be informed that the Council, while approving of the holding of examinations in midwifery-nursing by the Society, was adverse to the granting of certificates of proficiency, &c."

This was no sooner settled than, on the motion of Dr. BRUCE, "the previous question" was carried. A question arose whether the loss of the first resolution entailed the loss of the second, but Mr. Brown insisted on the latter being put to the vote.

The PRESIDENT said he had been actively opposed to the original certificate granted by the Society, but he felt that the Society had been instrumental in exerting a beneficial influence in improving the status of midwives, and he thought that the Society should not be interfered with so long as their certificate did not infringe the *Medical Act*.

Mr. BROWN said that if the Council did not feel inclined to deal with the matter now he would withdraw his motion and ask for the appointment of a committee.

After further discussion Sir W. THOMSON moved as an amendment that the measure be referred to a committee. He pointed out that the matter was one of considerable importance to the profession, in view of the practice that was growing up of getting the stamp of certain medical and surgical authorities for various purposes, a practice which was entirely opposed to the purposes of the *Medical Act*. He recalled the attitude of the Council last session, when attention was called to the certificates granted to spectacle makers, and this, he contended, showed that there was a ground for the charges which were originally made. This was seconded by Sir C. NIXON.

Dr. MCALISTER disapproved of the appointment of what might be called a "fishing committee," and Mr. BRYANT thought the matter was not ripe for action.

Sir W. THOMSON said he did not wish the committee to

fish for evidence, but there was a feeling that there existed an evil which required to be dealt with.

The amendment on being put to the vote was negatived by 14 to 6, and the original motion was also negatived by 21 to 5.

THE COMBINATION OF MEDICAL CORPORATIONS WITH UNIVERSITIES.

Mr. BROWN asked leave to postpone a motion which stood in his name, but this having been refused he brought forward a motion urging the various medical corporations in each division of the kingdom to take steps under Section 3, Clause C, of the *Medical Act* (1886) to combine with one or other of the universities to form a conjoint board of qualifying examination.

No seconder being forthcoming, Dr. BRUCE kindly filled the gap.

Mr. BROWN explained the tenour of his motion, which was negatived without discussion.

THE APOTHECARIES SOCIETY AND THE ENGLISH CONJOINT BOARD.

After a brief discussion as to the motion being in order, Mr. G. BROWN moved that the Council "strongly recommend" the Royal College of Surgeons of England, the Royal College of Physicians of London, and the Apothecaries Society to combine for the purpose of holding qualifying examinations conjointly. He pointed out that it was virtually only asking the Council to repeat a resolution passed in 1887. He recalled the strenuous efforts made by the then president of Council, Sir H. Acland, to induce these bodies to join, and he thought the time had come when these three corporations should be asked to combine.

Mr. VICTOR HORSLEY seconded the resolution merely because it was a step in the direction of the one-portal system.

Dr. MCALISTER pointed out that the University of London Commission Act had for object, *inter alia*, to incorporate these very bodies with the University of London.

After some remarks by Mr. TEALE, Dr. PYE-SMITH said he could not vote for the resolution because he did not think it would achieve the object aimed at, but he would not vote against it because he was in favour of the one-portal system. He thought there should be a single board in each department of the kingdom.

Sir RICHARD THORNE said he should vote for the motion as being a step in favour of the one-portal system, but Sir J. B. TUCKER, though in favour of the one-portal system, did not think the resolution would help them.

Sir DYCE DUCKWORTH urged that it was useless to do anything at this juncture, and they had better wait the resolution of the Commission.

Dr. GLOVER said he should vote for the motion, and Mr. BRYANT regretted that the combination did not take place when the conjoint board was formed.

Mr. CARTER recapitulated what the Society of Apothecaries had done in the matter, and he hoped that the combination would ultimately take place, though he could not vote for the motion.

Mr. BROWN declined a suggestion by the PRESIDENT that he should abstain from putting the question to the vote, and when put to the vote, 11 voted for, 8 against, 8 did not vote, and 3 were absent.

THE APOTHECARIES HALL IN DUBLIN.

Mr. BROWN then moved that it should be referred to the Irish Branch Council to consider and report as to the possibility of making arrangements for the institution of a conjoint Board for Ireland, to include the royal colleges, and the Apothecaries Hall. If the Council desired that these bodies should combine, the matter might be referred to a committee. The reason he had put this motion on the paper was that he received a report of the examiners of the Apothecaries' Hall, Dublin, and he blushed when he saw so much force was expended for so little result. The whole staff of examiners were brought to Dublin in many instances to examine only one candidate. It was nothing less than a scandal that in Dublin an examining body existed when so few candidates presented themselves. If this went on they would have to put the powers in force given them under the Act of 1886, and made representations to the Privy

Council that a certain body had ceased to be of importance.

Sir C. NIXON seconded the motion, though he feared in so doing that he was acting in opposition to the views of the representative of the Royal College of Physicians. In 1886 he had opposed such a combination because he had thought that if it could not enter into such a combination the Hall would cease to exist, but it did not cease, and they had the miserable spectacle of a competition, to which, as practical men, he thought they should try to put a stop.

Sir PHILIP SMYLY did not see how any recommendation could be considered with regard to a re-combination of the Colleges with the Hall.

Dr. LITTLE objected to the motion on the ground that the Irish branch had no money and could hold no meetings.

Dr. ATHILL said he had always been an advocate of the one-portal system, and denied that there had ever been any competition between the Colleges and the Hall.

Mr. BROWN thought as the Branch had no money it would be useless to refer the matter for their consideration, and offered to withdraw the motion. Leave to do this having been refused the motion was summarily negatived.

The Council then adjourned.

THIRD DAY.—THURSDAY, NOVEMBER 30TH, 1899.

PENAL CASES.

CASE OF DR. WILLIAM STEWART, OF DENTON.

The first item on the programme was the adjourned consideration of the case of Dr. William Stewart, of Denton, near Manchester, who appeared at the last session to answer a charge of having covered one Burgess, his assistant. The Council on the last occasion arrived at the conclusion that the charge brought against Dr. Stewart had been proved to their satisfaction, but adjourned the further consideration thereof. A letter was read from the Ashton Medical Society to the effect that they did not wish to press the case further since Dr. Stewart had discharged the unqualified person in question, and had resigned his appointment in the Denton Provident Dispensary, and asking the Council to take these circumstances into consideration at the adjourned hearing. A letter setting forth these facts, signed by Dr. Stewart's solicitor, was also read, and after a brief deliberation *in camera* the Council decided that the conduct complained of was not "infamous in a professional respect."

RESTORATION OF NAMES TO REGISTER.

A report of the Executive Committee with regard to the restoration of names to the *Register* was brought up, and the Council deliberated thereon *in camera*. On the admission of strangers it was announced that the following names had been ordered to be restored:—Robert Masters Theobald and George Hamilton Wyse.

ADJOURNED CASE OF MR. CLEMENT MAGUIRE KERSHAW.

This is the case of a dentist who was charged last session with employing an unqualified assistant. It transpired that he had discharged the assistant in question, and was employing a man who, though qualified, was not registered. Under the circumstances, the Council decided that the offence did not amount to infamous conduct in a professional respect.

CASE OF HENRY LOUIS GOODMAN.

This was another dental case, the person charged having been sentenced to a term of imprisonment for obtaining money by false pretences, and the Council, after deliberation, ordered his name to be erased from the *Dentists' Register*.

CASE OF MR. RICHARD THOMAS WILLIAMS.

Mr. R. T. Williams, L.R.C.P., L.C.C.S.Ed., of Port Talbot, Glamorganshire, was summoned to answer a charge of covering one Davies, an unqualified person.

Mr. Williams was unable to be present by reason of an attack of tonsillitis, this fact being testified to by the

doctor who is attending him. He was represented by his counsel, Mr. Eldon Banks.

The complaint was laid by Mr. James Herbert Powell, of Cwmavon, who was accompanied by his counsel, Mr. Arthur Powell. Evidence was given by a detective, Mr. Oxley, to the effect that the unqualified person was known in the village as "Dr." Davies, that he signed certificates for clubs, &c., and visited patients instead of his principal.

Mr. Powell, the complainant, in reply to Mr. Banks, the counsel for the defendant, explained that Mr. Williams was in partnership with Mr. Roberts, with whom he was not on speaking terms, and it was at Mr. Roberts's instigation that the detective was first employed. It appeared that there was a brass plate bearing Mr. Williams's name affixed to the door of the house occupied by the assistant, but it was stated that this house was formerly occupied by Mr. Williams, and the plate had not been removed. The complainant, through his solicitor, said that the assistant had since been dismissed and, so far as he was concerned, he did not wish to press the matter further, his object having been achieved. The detective, having been examined by members of Council as to how he obtained his information, a statutory declaration made by the assistant was read, setting forth that he was a *bona fide* medical student, having done part of his studies at the Middlesex Hospital. He denied having attended patients in place of his principal, or, in fact, of having done anything more than make a preliminary examination of patients until his principal could visit them. He only signed certificates when directed to do so by Mr. Williams.

Mr. Banks stated that Mr. Williams had applied to the Registrar of the Council for information as to what use he might make in his practice of a senior student, and had been provided with a copy of the resolutions of the Council bearing thereon. Mr. Williams had advertised for a qualified man, but in three weeks he had not a single reply, and, having seen Davies' advertisement, he engaged him until he could alight upon a qualified assistant.

The further hearing of the case was postponed until to-morrow, and the Council adjourned.

FOURTH DAY.—FRIDAY, DECEMBER 1ST, 1899.

On the Council reassembling, they went into *camera* to consider the Report of the Executive Committee with regard to the Restoration of Names to the *Medical Register*, and strangers were not admitted for a period of upwards of two hours.

ADJOURNED CASE OF MR. R. T. WILLIAMS.

After tea the Council resumed the consideration of the case of Mr. R. T. Williams, of Cwmavon, Glamorganshire. His counsel read statutory declarations made by certain of the patients who, it was alleged, had been attended by the assistant, denying that such was the case. It was stated that Mr. Williams was still unable to be present, and Mr. Davies, the unqualified person referred to, was put in the box.

Mr. Davies stated that he had not signed a particular certificate of which a copy had been produced, in which he was alleged to have signed his name as "Surgeon." He said he had been a medical student since 1889. He had only signed certificates at the request, and in the presence, of his principal, merely for convenience. In reply to Sir Christopher Nixon, he said he had passed his 1st, 2nd, and 3rd examinations for the M.B. of Glasgow, and was going in for his final in June. In reply to Sir Dyce Duckworth he attributed the delay in completing his studies to ill-health. Mr. TOMES asked to see the advertisement inserted by Mr. Williams, which was produced, and it appeared that it had been continued even after the engagement of Mr. Davies. He stated that his age was 30, whereupon Mr. G. BROWN asked at what age he had begun his medical studies. As Mr. Davies seemed somewhat embarrassed to reply, the President pointed out that this was merely a question of arithmetical computation.

Mr. Banks then addressed the Council on behalf of his

client. He pointed out that in the district where the practice was carried on people employed the term "Dr." very loosely, even the chemist and veterinary surgeon being thus styled. The incident of the plate bearing Mr. William's name being attached to the door of the house where Davies lodged was a simple inadvertence, the house still belonging to Mr. Williams, the plate having been left *in situ*. After some further remarks by Counsel for the complainant, the Council deliberated *in camera* and, on the admission of strangers, it was announced from the chair that the charge brought against Mr. Williams had not been proved to the satisfaction of the Council.

CASE OF MR. WILLIAM MATTHEWS JOYCE.

Mr. William Matthews Joyce, L.R.C.P., L.R.C.S. Ed., L.F.P.S., of Cattle Road, Birmingham, was brought before the Council under the following circumstances:— That in July, 1896, he had been convicted of being drunk and disorderly; and (2) that in November, 1899, he had been convicted of misdemeanor, viz., of assaulting one Ellen Simpson.

Mr. Joyce, who appeared in person, admitted the soft impeachment, but did not appear to be in a position to say anything in extenuation of his conduct. The Council having deliberated on the case *in camera*, on the readmission of strangers, the President, addressing Mr. Joyce, said that although his conduct had obviously been unworthy of a professional man, the Council had decided to take a merciful view of his case and had adjourned the further consideration thereof until next session, when he would be required to produce evidence that he had in the meanwhile behaved himself as a gentleman. Mr. Joyce then departed.

CASE OF FREDERICK WILLIAM KIRKHAM.

This was the case of one Frederick William Kirkham, of London Street, Chertsey, registered as L.R.C.S., L.R.C.P. Ed., who in October last was convicted at the Central Criminal Court of fraud. After a brief deliberation his name was ordered to be erased from the Register.

The Council then adjourned.

FIFTH DAY.—SATURDAY, DECEMBER 2ND, 1899.

L.S.A.'S AND THEIR TITULAR DESIGNATIONS.

A COMMUNICATION was read from the Society of Apothecaries in regard to the recent judgment bearing on the description that may be legally assumed by their licentiates, remitted by the Executive Committee. In this letter the Society contend that the judgment in question is to say the least unsatisfactory. They have taken the opinion of distinguished counsel, including Sir Edward Clark, who are of opinion that a licentiate is entitled to describe himself as Physician or Surgeon, or both, the case of *Hunter v. Clare* to the contrary notwithstanding. The Society suggest that a friendly action should be brought before the Court of Appeal or the House of Lords, each party paying its own costs. The Society emphatically disclaim any desire to assist its licentiates to appropriate any title belonging exclusively to any other licensing body. This letter was duly received and entered on the minutes.

Mr. B. CARTER pointed out that the licentiates must call themselves by a title of some sort, that of apothecary being archaic. Physician was obviously the proper term, it being an old English word, superseding the old word "leech," meaning nothing more than the practice of the healing art. He moved that the communication be referred to a special committee with power to take legal advice and to instruct the solicitor to take such steps as might be necessary to obtain the decision.

Sir BATTY TUKE said he held very different views from Mr. Carter, but would second the motion because the question was one that would have to be settled sooner or later, and it was the duty of the Council to remedy the confusion they had been the means of creating, a mishap which he attributed to important matters being held over to the fag end of the session instead of being taken earlier.

Mr. VICTOR HORSLEY proposed as an amendment (seconded by Dr. Bruce) that the words after "committee" be left out of the motion. He maintained that the opinion given by Sir Edward Clarke on the case as presented to him by Mr. Upton was valueless, and he did not think that it was the duty of the Council to spend money in clearing up the question. The task was one which would properly devolve upon the society. The decision might unfavourably affect the number of candidates for the licentiate, but that was not the concern of the Council. He concluded by moving "that the letter of Mr. Upton on the part of the Society on the subject of the use of the titles physician and surgeon be referred to a special committee to report to the Council."

Dr. MACALISTER expressed his concurrence with the amended motion, and suggested that they should add "with power to take legal advice."

Sir DYCE DUCKWORTH did not admit that the question was one of any great importance in view of the fact that very few men held the licentiate alone.

Dr. ATHILL observed that most medical men were known as "Dr.," and that in every profession there must be different grades. He had great respect for the L.S.A., but did not think that the Council would be justified in spending money for this purpose.

Mr. BROWN challenged the exclusive right of any particular class of practitioner to the use of the word "physician." He was proceeding to refer to the Medical Act of 1858 when the President called him to order, observing that Mr. Brown was entailing great expense to the Council by his lengthy remarks, it not being the first occasion on which he had done so.

Mr. HORSLEY objected to the introduction of the permission to take legal advice. They required time to consider the point, and the appointment of a committee would give them the time.

The amendment was then put to the vote, and was carried by 22 to 5.

Dr. MACALISTER then moved the addition of the words "with power to take legal advice." This was seconded by Mr. Carter.

On being put to the vote the amendment was lost.

Mr. Horsley's amendment was then agreed to as a substantive motion, the nomination of the committee being left in the hands of the President.

ADDITIONS TO PENAL AND DISCIPLINARY POWERS.

Mr. BRYANT brought forward the report of the President on the steps taken by him to have Section XXIX. of the *Medical Act* (1858) amended so as to secure increased powers for penal and disciplinary purposes, and moved that he be requested to forward to the Privy Council the draft clauses as amended, with the expression of a hope that the Privy Council would support a Bill in Parliament to have them made law. The purport of this report is to confer on the Council the power to erase a name from the Register for a specified period, such name to be restored at the expiration of that period if such person then possessed a medical diploma. Also to confer on the various medical authorities the right to revoke, suspend the use of or cancel, diplomas held by a person whose name has been erased from the Register, with power to restore such diploma without the necessity of fresh examination. The report also deals with the allocation of fines and penalties recovered under the Medical Acts in the Metropolitan Police District and elsewhere, and defines the meaning of the terms employed.

After some remarks by Dr. BRUCE and Dr. PYE-SMITH, Dr. LITTLE asked who would take the first steps, whether the Council or the licensing body. The President replied that the body which suspended the diploma would, of course, take the initiative in restoring it.

Sir RICHARD THORNE raised the question as to what would happen if the medical authority restored the diploma and the Council declined to reinstate the name on the Register.

The motion was then carried.

RECIPROCITY OF MEDICAL PRACTICE.

The report of the Executive Committee on reciprocity

of medical practice in relation to foreign countries was received and entered in the Minutes.

This report embodied a statement by Mr. Muir Mackenzie to the effect *inter alia* that a foreign practitioner in the United Kingdom was bound by the laws in force, and was in the position of a practitioner who is not registered. Mr. Mackenzie recalled that under the Medical Act, 1886, the Queen in Council might apply the part of the Act which related to foreign practitioners to any foreign country which, in the opinion of Her Majesty, affords to the registered medical practitioners of the United Kingdom such privileges of practising in the foreign country as to Her Majesty may seem just, whereupon the Council would be empowered to grant recognition to such medical diplomas of the foreign country as to the Council appeared to furnish a sufficient guarantee that the holder of the diploma possessed the requisite knowledge and skill for the efficient practice of his profession. These diplomas would then be admitted to registration. Failing the consent of the Council to recognise a colonial or foreign diploma the Privy Council might, if they thought fit, after communication with the Medical Council, order it to recognise the said diploma.

The Executive Committee recommended:—"That the General Council be recommended to authorise the issue of Mr. Muir Mackenzie's statement of August 10th, 1899, as an expression of the Council's views in regard to its legal position in connection with the question of Reciprocity of Practice; and that the Executive Committee recommend that the General Medical Council represent to the Privy Council that the time had arrived when Her Majesty in Council should apply Part II. of the Act of 1886 in respect of foreign practitioners to the Kingdom of Italy."

After a brief discussion it was agreed "that the Council adopt the statement made by Mr. Muir Mackenzie with respect to the state of the law in England as to reciprocity of medical practice in foreign countries, and that it be introduced into an amended edition of the Memorandum to be reissued. On the motion of Dr. MACALISTER it was agreed that the statement should be translated into French.

Sir DRCE DUCKWORTH pointed out that British practitioners would be shut out from practice in Italy unless the Council interfered. He spoke highly of the Italian diplomas, and urged that for one Italian practitioner who would come to this country there would be ten British practitioners who would desire to practise in Italy. He concluded by moving the recommendation of the Committee above.

Dr. LITTLE asked why no steps were taken to induce other countries to allow British practitioners to practise their profession, Italy being alone in allowing British practitioners to practise without obtaining a native qualification.

Dr. McVAIL pointed out that if the Council granted reciprocity to Italy, they would be constrained to adopt a similar course in regard to other countries.

Mr. HORSLEY urged that if Italian practitioners were allowed to practise in this country they would compete with native practitioners, adding that the latitude allowed by the Italian Government was simply due to the fact that English visitors were a large source of revenue to that country.

Dr. MACALISTER pointed out that Colonial practitioners had not shown any great desire to flock to this country, although they possessed many obvious advantages over foreign practitioners, in their knowledge of the language, &c.

Sir RICHARD THORNE urged that the Council should make sure of the exact condition of things in Italy before taking any decided step.

The further discussion was adjourned.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, December 8th, 1899.

COXALGIA.

At the last meeting of the Surgical Society, M. Nelaton

spoke on resection of the hip for coxalgia, and said that radical operation was not generally practised in such cases, surgeons contenting themselves with conservative treatment. Twice he had resected the hip for suppurating coxalgia, and the results were such that he considered that surgeons should have recourse more frequently to this operation.

The first case was that of a woman, æt. 28, treated for two years without success by the conservative method. After the coxa-femoral resection, in the course of which he had removed a considerable portion of the iliac bone, the patient recovered completely, and walked better than could have been expected from any other method of treatment.

The second was that of a boy, æt. 15, who six months before was operated upon in a similar manner to the preceding, and in three months he was able to get about comfortably, although the hip was ankylosed. The speaker concluded by saying that his remarks of the expediency of the operation referred to adult persons and not to children, in whom it was right to expect much from the conservative treatment.

M. Félizet remarked that the history was known of 100 individuals suffering from coxalgia in their childhood, it would in all likelihood be found that out of that number not more than a dozen were alive at the end of twenty years, all the others having succumbed to complications. Consequently, no one should hesitate to utilise a radical operation, and the resection should be practised at an early date of the malady. For his part, he employed it in children in about 300 cases, and thanks to the actual cautery he had obtained excellent results. Generally, he made the first dressing twenty days after the operation. When the shortening, which ordinarily was one inch, attained one-inch-and-a-half, or even more, it was easy to correct it by an apparatus.

CEREBRAL HEMORRHAGE AND THE SIGN OF KERNIG.

M. Vidal, in speaking at the Medical Society, said that he had recently observed in a case of meningeal hemorrhage which had been revealed to him by the existence of Kernig's sign. A man of 38 was seized suddenly with an apoplectic attack. When he recovered consciousness a few hours afterwards he presented neither fever nor paralysis. He complained only of intense headache, pain in the back, while the pupils were somewhat dilated. The existence of the sign of Kernig was observed, and a lesion of the meninges was immediately suspected. In the dorsal position, the man could keep his legs extended on the thighs, but once he was seated on the edge of the bed, his legs were drawn towards the thighs. Five days after the accident the temperature rose somewhat, and on the ninth day the patient succumbed. When the cranium was opened a clot of blood was found beneath the arachnoid and extending down towards the bulb, while the rhachidian canal was filled with blood. The clot then did not intersect either the circumvolutions of the base of the brain or those of the convexity. That fact proved that the sign of Kernig could exist independently of all inflammation of the coverings of the cerebral circumvolutions, and that its *raison d'être* was rather to be imputed to an irritation of the spinal membranes. If the sign was more frequently absent in tuberculous meningitis than in cerebro-spinal meningitis, the reason probably was that in the first-named affection, the rhachidian membranes were less affected than in the second.

GRAVE PULMONARY AFFECTIONS.

M. Raynaud communicated several cases of pulmonary affections treated by him by blood letting, and the injection of artificial serum, and insisted on the necessity of sustaining the organism in its struggle with the microbial poison and to favour its elimination; blood letting acted mechanically in that sense, and by injecting at the same time the saline solution, the blood withdrawn was replaced, the toxins diluted, the heart stimulated, the tension and the diuresis increased. The amount of blood withdrawn was from six to ten ounces, and that of artificial serum injection seven to twenty ounces.

Germany.

BERLIN, December 2nd, 1899.

IODINE AND ITS COMBINATIONS.

DR. HEINTZ, of the University of Erlangen, has an article on this subject in a recent number of *Virchow's Archiv*. His investigations into the behaviour of iodoso-benzoic acid and on the influence of the iodine alkali on absorption are of special interest. Iodoso-benzoic acid discovered by V. Meyer, possesses the property when applied locally of splitting off free iodine in contact with iodine-alkali circulating in the blood. If for example iodoso-benzoic acid mixed with starch is injected under the skin of the rabbit, and an injection of an iodine solution is made into the blood current, the starch is coloured blue by nascent iodine. By the local application of iodoso-benzoic acid therefore, and the simultaneous administration of iodine per os, we have the means of exciting a lasting action of iodine at the place of selection, but the iodoso-benzoic acid acts as a powerful irritant. The author attributes the resorptive properties of iodine to its influence on the leucocytes. Great proof of this hypothesis has hitherto not been at hand; the leucocytosis that follows the introduction of iodine also follows the introduction of indifferent salts. It might be supposed that the iodine alkali in the blood or tissues was split up in the region of greatest tissue change therefore in the leucocytes, the free iodine then acts back on the leucocytes and excites them to greater resorptive activity.

THE TREATMENT OF CHLOROSIS AND ANÆMIA.

Few subjects have been more written about than the one named. Considering the ease with which such cases are generally improved, this is perhaps a matter for surprise. But now and then cases are to be met with that persistently resist our efforts to improve them, and here it is that the possible value of a multitude of counsellors comes in. In view of these difficult cases it behoves us not to neglect any source of possible aid. A recent writer on this subject is Dr. Frieser, who devotes an article to it in the *Klin. Therap. Wochens.*, 42 99. According to him treatment must take three directions—the direct medicinal, the symptomatic, and the hygienic-dietetic, and he must first of all seek to restore the lost equilibrium of iron in the system. To this end resorbable and assimilable iron must be introduced into the system in sufficient quantity, care being taken not to disturb the digestion. He would exclude all the inorganic preparations of iron, as they are inferior to the ferratin an

iron combination made from the animal liver. His experience with the preparation extends to fifty-nine cases, thirty-three of secondary and chronic anæmia, and twenty-nine of chlorosis. In eighteen cases of anæmia and fourteen of chlorosis ferratin was given exclusively with specially good results. In two tolerably severe cases no special result was observed, whilst in four cases of anæmia with complications, it was not well borne, but subcutaneous injections of a 6 per cent. solution gave very good results. In other cases various preparations of iron were given with varying, mostly unsatisfactory, results. The ferratin was generally given as a powder along with a little rhubarb. (Ferratin, 1 to 3 grms., pulv. rhei, 0.1 to 0.4 grms., two or three times a day.) No fruit or acid foods were allowed during the treatment. Quinine iron wine was a useful aid.

The symptomatic treatment was mostly of the side of disordered digestion. Absence of appetite was generally assisted by small quantities of Carlsbad Mühlbrunn water drank slowly on the empty stomach before breakfast. In many cases Penzoldt's wine was of service. Lowered intestinal function was relieved by intestinal infusions with luke-warm water with salt, or under certain circumstances oil injections. Much may be expected by appropriate massage and weak Faradaic currents. In cases complicated by chronic diarrhoea only the most careful regulation of the diet was of service.

Dietetic hygienic treatment embraced all the measures necessary for ensuring a well-regulated mode of life. First of all everything that interferes with the function of the bowels must be removed. The food must be easily digestible, non-irritant, and as varied as possible. The chief food must be milk, meat roast or scraped, and soft eggs. But milk cannot always be taken in sufficient quantity by adults, it sometimes causes diarrhoea and a constant feeling of fullness. Patients must be careful, and be protected from overwork, bodily exercise in the open is of great value, but oftentimes bad cases of both anæmia and chlorosis required prolonged rest in bed. Almost always such cases require an extra allowance of sleep, and this should be provided for them. Special stress must be laid on personal cleanliness. The mental and sexual functions must be watched over.

As regards hydrotherapeutics daily rubbings are useful, and act beneficially on the general health and on the strength; but a systematic hydropathic treatment is rarely admissible; but on the other hand massage and faradisation are sometimes exceedingly useful in anæmics.

At the Medical Society, Herr Virchow opened a discussion on Richter's paper on

ORGANOTHERAPEUTICS.

He said he remembered Rademacher's "Organotherapy," and the difference between that and the present; further his essay "Specifica and Spezifisches" (in his *Archiv*), wherein he drew attention to the necessity of finding certain relations between therapy and local pathology as a matter of fact, certain organs were specially susceptible as regarded certain remedies. In the new kind of organotherapeutics he missed the theoretical connection between therapy and the general pathology of the present. The idea of using a whole organ—an ovary for example, for the preparation of the desired remedy appeared to him

monstrous, and corresponded to the first raw beginnings of "Koch Kunst." It was impossible for all the constituents of the ovary to come into consideration as active agents, but only certain groups of cells, possibly the Graafian follicles. The discovery of the peculiar active substances was of the greatest importance in the inquiries now being conducted. The alleged reimplantation of already extirpated ovaries with subsequent recurrence of functional activity we must relegate to the region of the stories from "A Thousand Nights and a Night."

Hr. Burchardt related again the case of a girl of 20 who weighed, without clothes, 158 lbs., on whom treatment by oöphorin tablets was successful. She generally took about fifteen a day, and after taking 1,000 her weight fell to 142 lbs. (March to July). She increased in weight again when treatment was interrupted, but again fell off when it was resumed, but not to so great an extent as at first. Organotherapy under proper medical control, was absolutely harmless, and very encouraging.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, December 2nd, 1899.

THROMBUS IN TRANSVERSE SINUS.

At the Gesellschaft der Aerzte, Politzer showed a boy, æt. 14, who had suffered from otorrhoea since an attack of measles when he was six years of age. Five weeks ago the boy became suddenly ill with vomiting, vertigo, and headache, for which it was decided to perform trepanation of the mastoid portion of the right temporal bone. Six days after the operation, when the patient was recovering rapidly and all anxiety was considered over, cerebral phenomena suddenly occurred which excited alarm. The original wound was re-opened and extended into the transverse sinus, from which pus discharged, where a thrombus 4 centimètres (0.39 of an inch) was found firmly impacted. After careful removal and washing the patient recovered without a bad symptom.

Sinus thrombi are not uncommonly found after chronic discharges from the ears owing to the proximity of the vascular plexus where the inflammation is conducted to the wall of the sinus and the changes induced. The site of the thrombus is never constant, as it may occur anywhere, even in the vena jugularis communis itself, but wherever situated the prognosis is always grave. The most effectual method of reducing the fatality is an early opening into the petrous bone. Since 1896 70 cases have been published, 41 of which have recovered. In his own cases he had had 15 sinus thrombi with 10 recoveries, and 14 peri-sinus abscesses, with 7 recoveries.

TABC AFFECTIONS OF BOTH KNEES.

Sternberg next exhibited a man with tabic affections of both knees and lower bones. In 1876 there was a history of a genital affection with subsequent copper-coloured spots on the arms and legs. Fifteen years later there were severe pains in both legs and swelling in both knees, with enlargement of the upper ends of the tibia and fibula which increased and diminished temporarily. In 1897 the swelling confined itself to the

left leg, but in 1898 it invaded the right, where it has remained stationary ever since, while the bones have become bent in the shaft. Tendon reflex has disappeared, as well as the distinction of heat when rapidly placed in warm and cold water. The case was generally diagnosed as one of tabes or syringomyelitis with bone affection.

LUMBAR EXTRAVASATION.

Lanyer next brought forward a coachman with a large fluctuating tumour in the lumbar region. According to his story he was getting down from the box when he slipped and fell hurting his leg and back. A few days after the fall a fluctuating swelling was discovered in the lumbar region. It seems that the fall, with the muscular movements, had caused a tearing of the subcutaneous cellular tissue, with an effusion of lymph. Levellée and Gussenbauer seem to have been the first to draw attention to these extravasations as being difficult and protracted in resolution. Pressure alone will not effect the object, and even when combined with iodine injections it frequently fails in accomplishing a cure. Free incision and allowing the cavity to heal by granulation is the most effectual procedure.

Weinlechner remarked that in these cases blood extravasation co-existed with the lymph.

Schopf challenged this assertion of Weinlechner's, and pointed out that there was a vast difference between a hæmatic cyst and lymphatic effusion, as the former appeared rapidly after the injury, while the latter did not appear for days after, as evinced in the case shown by Lanyer. He exhibited two cases from his own wards to prove the differential diagnosis.

ÆTIOLOGY OF TABES DORSALIS.

Benedikt next read to the meeting a long paper on the ætiology of tabes dorsalis which he maintained was purely hereditary in origin. All other causes, such as exhaustion, violent exertion, illicit excess and colds, were only immediate exciting causes in persons predisposed to the disease. What part syphilis played in the disease was difficult at the present time to determine, but present day statistics were certainly against Erb's figures, which he used twenty-two years ago to vindicate his opinion that syphilis was the sole cause of this obscure disease. Benedikt then adduced his own investigations and found that in every hundred cases examined fifty-two were positively free from syphilis; thirty-four had been infected; while thirteen remained doubtful. It is quite conceivable, however, that mercury and iodide when given in large quantities for syphilis will induce tabes dorsalis in the predisposed.

A large number have syphilis and no tabes dorsalis follows the disease, while a large number have tabes dorsalis without any trace of syphilis.

DOCTOREN COLLEGIUM.

This institution will have reached its 500th year on the 10th of December. To commemorate the occasion a "Festrede" will be given by the Vice-President, Dr. Svetlin, who will probably tell his hearers how Johann Silber opened this institution 500 years ago as the "Acta facultatis medicæ Universitatis Vindobonensis," the first institution formed after the foundation of medicine in Vienna.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

CHOLECYSTOTOMY.—Mr. CARLESS operated on a woman, æt 60, who had suffered from recurrent attacks of pain in the right hypochondrium for some months. She had never been badly jaundiced, but the conjunctivæ were slightly yellow, and after an attack of pain there was a slight yellow tinge about the skin. The attacks of pain were of a colicky nature, and so severe as to exhaust the patient, and she was sent to hospital by Dr. Jardine, of Richmond, as he feared that after one of these paroxysmal seizures she might collapse. The patient was a fat, flabby woman, who looked an unfavourable subject for abdominal operation. She was anæsthetised with A. C. E., and, after efficient purification of the abdominal wall, an incision six or seven inches in length was made parallel to, and about one inch from, the right costal margin, extending downwards and outwards from the middle line above. After opening the abdominal wall, the liver, which was somewhat enlarged, came into view, and on lifting its free border, a few adhesions had to be divided between the duodenum and the gall-bladder, which last at once came into view. The fundus of the gall-bladder was found to be occupied by a hard lump about the size of a walnut, over which the wall of the viscus was firmly adherent, the proximal end of the gall-bladder appeared to be normal. The abdominal cavity was now shut off by a packing of cyanide gauze wrung out of hot sterilised salt solution, and the liver with its attached gall-bladder drawn out of the wound which was in this way plugged. An incision was now made through the walls of the gall-bladder, and by this means the hard mass was exposed, and found to consist of a collection of small black gall-stones held together by a cement-like substance, evidently consisting of inspissated mucus and bile salts; the whole of the stones and the *débris* were removed by means of a lithotomy scoop and a Volkman's spoon which had to be used somewhat energetically in order to detach the calculi from the gall-bladder wall. A small communication with the rest of the gall-bladder was found, and down this a long probe was insinuated but no further calculi were discovered. A small amount of healthy bile escaped from the wound. The free wall of the pouch in which the stones had been laying was cut away. The posterior wall of the pouch was freely curetted, and the opening closed entirely by a double row of Lembert's sutures. The gauze packing which was scarcely soiled, was then removed, and the liver replaced in the abdomen; a small lamp-wick drain of gauze was inserted down to the wound in the gall-bladder, the whole of the extensive abdominal wound closed by a double row of buried stitches, and a superficial continuous suture for the integuments. Mr. Carless remarked on the extreme simplicity of the operation in this particular case. The stones were lying in a part of the gall-bladder which was practically shut off from the biliary passages; the liver was large and could be pulled out of the abdominal wound, so that the opening of the gall-bladder could be done outside the abdomen. There was quite sufficient evidence of old peritonitis to explain the symptoms from which the woman had suffered. Surgeons, he said, differed somewhat in their method of treating the gall-bladder after the removal of stone. In the majority of instances a biliary fistula was established,

and the immediate closure of the wound in the gall-bladder was not a favourite proceeding; he had, however, followed this practice several times with complete success, and unless there were some definite reasons demanding drainage, such as suppuration, he would certainly feel inclined to close the gall-bladder at once. In this particular instance it would have been ridiculous, he thought, to leave a biliary fistula.

It is satisfactory to report that the patient recovered without a bad symptom, the deep lamp wick drain was removed in forty-eight hours and replaced by a more superficial one, which was in turn taken out at the end of the fourth day. The whole wound was closed in a fortnight, and the patient was out of the hospital in less than three weeks.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 6, 1899.

THE GENERAL MEDICAL COUNCIL.

WHEN the Council adjourned on Saturday last there seemed to be every prospect of the Session extending far into the present week. A certain amount of work has been got through, including a number of penal cases, none of which presented any particular interest, but we fear it cannot be asserted with confidence that the net result of so much talk has been to advance medical interests to any material extent. An interesting little discussion arose on the large proportion of Irish candidates who were unsuccessful at the competitive examinations for admission to the Services. Mr. Brown saw in this lack of success a proof that the examining bodies in Dublin were not up to the mark, but the Council, recognising how fallacious must be a conclusion based on a single set of results, bearing on some half-a-dozen candidates, refused to allow the matter to be referred to a committee. We decline to believe that the Services are unpopular with Irish diplomates, and the explanation, if any be needed, must be sought else-

where. Obviously the Service competitive examinations afford an excellent opportunity of estimating the status of the various qualifying boards, and the Council would be ill-advised not to derive from these lists such information as may be gleaned. Mr. Brown's suggestion, therefore, is right in principle, and may serve as the basis of future scrutiny. Something very like a scene occurred in connection with a speech delivered by Mr. Brudenell Carter in refutation of certain allegations made by Mr. Victor Horsley, reflecting on the constitution of the body of which Mr. Carter is the representative, and on Mr. Carter's conduct in the notorious Hunter case. Unfortunately for Mr. Horsley the very drastic criticisms which he had made with regard to the constitution of the Society of Apothecaries of London proved to be grotesquely erroneous, and although he duly swallowed the leek and apologised for his misstatements, one could have wished that he had verified his references before making them the basis of scathing denunciations from the forum. Having exposed himself to correction he has no right to complain if Mr. Carter, with studied vindictiveness, availed himself to the utmost of his opportunity, but if the *fond* of Mr. Carter's remarks was good the form left much to be desired. Mr. Carter complains that while the medical journals give ready publicity to speeches adverse to himself they usually suppress his replies. We cannot admit the justice of the reproach as addressed to ourselves, but when our readers have perused the report, published elsewhere, of Mr. Carter's most recent utterances, they may possibly come to the conclusion that the reticence of which he complains was all to his advantage. Personalities between members of public bodies are to be deplored, because they impede the course of business and import an element into the debates which is foreign to their intention and detrimental to their utility. We cannot say that Mr. Carter has succeeded in explaining away his behaviour in respect of the prosecution of the late Mr. Hunter. If he was really unaware of the fact that Mr. Hunter was a licentiate of the Society of Apothecaries and a registered practitioner, that was a serious piece of negligence on his part. The proposal that the Council should share with the Society the expense of an appeal with the view of establishing once for all the titular position of its licentiates is hardly one that can commend itself to business men. If, as the legal advisers of the Society contend, the decision is wrong, it is open to the Society to take such steps as they may select to have it redressed, and the most the Council can be expected to do is to abstain from active opposition. Mr. George Brown, who has been very much *en evidence* this session, brought up the vexed question of the Obstetrical Society's examination for midwives which we hoped had been laid to rest by the Society's acceptance of the amended form of certificate, suggested by the Council, which comprises a footnote expressly stating that the certificate in question confers no privileges under the Medical Acts. However much one may sympathise with

the Obstetrical Society in its endeavour to raise the educational status of the midwife, the principle of the granting of certificates of proficiency is obviously one to be condemned, especially as the example has been followed by various other medical and non-medical bodies, in contravention of the spirit, if not of the letter, of the Medical Acts. Still, as the Council has inadvertently given a quasi-approval to the present form of certificate, and as legislation which will render the exercise of their present functions as examiners supererogatory, is probably within measurable distance of becoming law, the opportuneness of resuscitating this delicate question may well be questioned, and the action of the Council in declining to take further action therein for the present will doubtless meet with a qualified approval. One of the most interesting points brought out in the discussion of Mr. Brown's motions in favour of a combination between the Royal Colleges in London and Dublin and the respective Corporations of Apothecaries is the existence of a strong feeling in favour of the one-portal system which, just when it appeared to be on the eve of accomplishment, was relegated to obscurity, but apparently not to oblivion, by the Medical Act of 1886. So far as the Metropolis is concerned, the motion was inopportune, seeing that the Commission entrusted with the organisation of the new University of London has for mission to consider the means of incorporating the three licensing bodies in question with the University. Moreover, a mere recommendation to conjoin would not be likely to exert greater influence at the present juncture than did the strenuous efforts of the President of Council after the passage of the Act of 1886. Even less likely of success would be a recommendation addressed to the colleges in Ireland because the waning popularity of the Apothecaries' Hall in Dublin encourages hopes, probably doomed to disappointment, of its approaching demise. We must comfort ourselves for the nonce with the reflection that there is a growing feeling in favour of the unification of licensing bodies in each division of the kingdom, a feeling which will doubtless find expression when a suitable opportunity presents itself. Without indulging in unduly sanguine anticipations, we are entitled to hope that the definite attitude of the Council in the matter of the much-needed reform of the present system of death certification will bear fruit in due season. The Government cannot well refuse its support to a measure the necessity for which has been demonstrated over and over again, and we trust that the next session of Parliament will provide the public with additional safeguards against criminal practices which are positively facilitated by the present slipshod system.

THE USE OF DIPHTHERIA ANTITOXIN IN AMERICA.

THE most recent statistics upon the subject of the use of diphtheria antitoxin in America are contained in a report issued by the Department of Health in the City of Chicago. Therein it is stated that from

October 5th, 1895, the date of the first administration of antitoxin by the Department, to February 28th, 1899, a period of nearly three years and a half, a total of 6,342 reported cases of diphtheria were visited by the department inspectors. Of this number 4,311 were bacteriologically verified as true diphtheria, and 4,076 were treated with antitoxin, the remaining 235 being treated elsewhere. The results show that there were 3,795 recoveries out of the total number treated by the department. The fatal cases, however, numbered 276, and at the end of February, 1899, there were five cases still under treatment. Examination of these figures will show that the mortality rate was 6.77 per cent. in 4,071 cases of the disease verified by bacteriological examination, and treated by antitoxin. This remarkably low mortality is certainly significant, more especially as we learn that since the antitoxin has been used a decline in the death rate has occurred of 43 per cent. Such a marked improvement as this in the number of fatal cases is certainly convincing testimony to the efficacy of the method of treatment, and whatever may be said to the contrary, the fact remains that only 6 per cent. of the persons attacked with diphtheria died. But further points of interest are contained in the report. It is mentioned that among 355 cases treated on the first day of the disease only one death occurred; that is to say, a mortality of 0.28 per cent.; in 1,018 cases first treated on the second day of the disease there were seventeen deaths, or a mortality of 1.67 per cent.; in 1,509 cases first treated on the third day of the disease there were fifty-seven deaths, or a mortality of 3.77 per cent.. Again, in 720 cases first treated on the fourth day of the disease there were eighty-two deaths, or a mortality of 11.39 per cent. Lastly, in 469 cases first treated later than the fourth day, there were 119 deaths, showing a mortality of 25.37 per cent. Thus these figures conclusively prove the importance of using the antitoxin as early as possible. So far, however, as the latter point is concerned, it has for some time been known in this country that the efficacy of the remedy was much greater the earlier that it was applied. It would have been interesting to have had some information respecting the frequency of albuminuria in the cases treated by the Chicago Department of Health. As is generally known, Mr. Lennox Browne in this country has brought out some startling facts in connection with this part of the subject. If the use of the antitoxin tends to the development of albuminuria, this would constitute a very material objection to its administration. But more statistics are needed on this point.

SINGLE DIPLOMAS.

A FORTNIGHT since we corrected a statement in the *British Medical Journal* to the effect that a single diploma can be by itself a qualification under the Medical Act of 1866, and we referred to the third section of the Act as authority for our asser-

tion. Our contemporary pretends to controvert this statement to which we now, nevertheless, strictly adhere. The section is, *verbatim*, as follows:—3.—(1) A qualifying examination shall be an examination in medicine, surgery, and midwifery held, *for the purpose of granting a diploma or diplomas conferring the right of registration* under the Medical Acts, by any of the following bodies, that is to say:—(a) Any university in the United Kingdom or any medical corporation, legally qualified at the passing of this Act to grant such diploma or diplomas in respect of medicine and surgery; or (b) Any combination of two or more medical corporations in the same part of the United Kingdom who may agree to hold a joint examination in medicine, surgery, and midwifery, and of whom one at least is capable of granting such diploma as aforesaid in respect of medicine, and one at least is capable of granting such diploma in respect of surgery; or (c) Any combination of any such university as aforesaid with any other such university or universities, or of any such university or universities with a medical corporation or corporations, the bodies forming such combination being in the same part of the United Kingdom.

It will be seen that no qualifying Body save a University can grant qualifying diplomas independently, and that even its diplomas do not qualify unless they represent medicine and surgery separately. It is true that under the 5th section "a Medical Corporation which represents to the General Medical Council that it is unable to enter into such combination" (with another Body) can act alone if it causes the Council to appoint assistant examiners in the speciality which it does not profess. In other words, if it be a medical body it must obtain surgical examiners and *vice versa* if it be a surgical body. Outside these arrangements all qualifying bodies may grant any diplomas they please. An apothecaries hall might grant a diploma in aeronauts, just as the spectacle sellers grant one, but such diplomas are only decorative and have no effect as qualifications. The whole controversy arises out of a play on words which our contemporary has originated. It tells us that "the Local Government Board recognises these single diplomas and its possessor would thus, *if registered*, be entitled to hold a Poor-law appointment," and again, "a medical body which fulfils the *statutory requirements* is able of itself to grant a single 'fully qualifying diploma.'" Yes; but no such diploma, *per se*, can be registered or can "fulfil the statutory requirements." We are quite well aware that, of his own mere motion and without any authorisation from the General Medical Council, or, as we judge from the law, the late President of that Council ordered the registration of a number of individuals who presented no other credentials save the medical degrees of the London University, but we protested, at the time, that his doing so was a totally illegal assumption of authority, and we still believe that anyone who chose to take the trouble could cause every one of the entries to be erased.

Notes on Current Topics.

Free Medical Aid to Soldiers' Families.

THE proposal that medical men should give practical help to the movement for relieving the wives and families of soldiers engaged in the South African war is founded on a knowledge of the humane generosity that we are glad to believe animates the medical profession. The gratuitous service already accorded to the community from that quarter is well-nigh incalculable, indeed, if we may believe complaints that have flooded medical journalism for the past half century or more, the habit has led to a crop of sorry abuses. From that point of view it may be well to utter a word of caution as to the manner in which this latest military relief scheme is carried out. The organisers, so we are told by a London morning paper, have been bombarded with offers of free attendance from leading practitioners of the West End. Surely, as regards the honorary surgeons and physicians of hospitals, dispensaries and other medical charities, attendance at their institutions would already provide the aid that is asked for. In every district there are scores of general practitioners who would be willing to extend their list of gratuitous patients so as to include the families of soldiers at the war. The published method of the Soldiers' and Sailors' Families Association is to look up the wives of all the soldiers at the front. Should they discover a case needing medical help they communicate at once with one of the free doctors, who attends the patient and sends on the prescription to the free chemist. Without careful precautions this plan opens the door to undesirable competition and jealousy, although at the same time it is impossible to withhold a cordial approval of the general tenour of the scheme.

"Madame Frain."

WE noted last week that the nest of criminal swindlers who have been making handsome profits by catering for women (married and unmarried) who desire abortion have met with condign punishment at the hands of Mr. Justice Darling. The fact is highly gratifying, because a number of pests of society have been stopped in their pernicious trade, but the greater satisfaction arises from the determination, by the learned Judge, of legal principles which will be invaluable as governing a multitude of future cases. Our readers may recollect that the MEDICAL PRESS AND CIRCULAR was the first medical journal to call attention, some three years ago, to the advertisements of "Madame Frain" when we brought them under the notice of the Public Prosecutor who favoured us with an explicit statement of his view of the law to the effect. (1) That the advertisements were not, of themselves, so obscene as to justify prosecution. 2. That a prosecution neither under the Pharmacy Acts for dispensing without qualification nor under the common law for administering noxious drugs would lie, because, in fact, the medicines sold to the dupes of the firm consisted only of dirty water, and had no emmenagogue potency what-

ever. 3. That the only prosecution which could be effectually maintained would be one, promoted by a victim, for obtaining money under false pretences, a suit which it was very unlikely that any of "Madame Frain's" customers would be induced to enter upon. The prosecution now instituted and the judgment of Mr. Justice Darling have effectually corrected this view of the law. In the first place it was proved that the "Frain" medicines contained a proportion of abortive drugs which might produce the desired result or, if in larger quantity, might kill the patient. Next it was ruled by the learned judge that it was not at all necessary that they should prove this in order to justify a conviction, inasmuch as the vendor of and the purchaser of an abortion medicine were equally liable to the law whether the medicine was or was not what it professed to be. Third, and perhaps most important of all, that the proprietors of newspapers which publish the advertisements of such medicine would be amenable to the law as *particeps criminis*. Considering that it was stated in Court that some of the newspapers (mostly the pious ones) which inserted these advertisements charged at the rate of £7 10s. per inch of space, for which their legitimate cost would be about half-a-crown, it appears that the judge's warning to the journalists comes none too soon.

Tobacco Pipes and Guy's Hospital Subsoil.

REFERRING to our remarks under this heading last week, a correspondent considers that the presence of these tobacco pipes is a strong confirmation as to the conjecture that the bones are those of plague victims. In the seventeenth century tobacco was regarded as a powerful prophylactic, and the faculty strongly recommended everybody to smoke. Those concerned in the burial of plague corpses would, doubtless, be furious smokers, and, probably, as a measure of precaution, would throw away their contaminated "caddies" before leaving the dismal spot. Dr. Charles Creighton, in his work on "Epidemics in England," refers to smoking as a preventive of plague, and quotes the following quaint extract from Hearne, the antiquary, who writes:—"I have been told that in the last great plague at London" [that would be in 1665] "none that kept tobacco shops had the plague. It is certain that smoking was looked upon as a most excellent preservative, inasmuch that even children were obliged to smoke. And I remember that I heard formerly Tom Rogers, who was yeoman beadle, say that when he was that year, when the plague raged, a schoolboy at Eaton, all the boys of that school were obliged to smoke in the school every morning, and that he was never whipped so much in his life as he was one morning for not smoking." Does this not tend to show that a plague pit exists beneath Guy's? It also demonstrates what a curious animal is the boy. He is whipped in the seventeenth century for not smoking according to commands, whilst now (or, at all events, a few decades ago he was) flogged for smoking against orders! This goes to prove that when doctors deal with boys, they should prescribe in exact opposition to their wishes

in order to give a fair chance to the science of medicine.

"Floreat Hibernia Semper."

THE above is the motto of the Irish Medical Schools' and Graduates Association, whose autumnal dinner, attended by members and guests to the number of 180, took place at the Hotel Cecil, on Wednesday, November 29th last. Sir William Thomson, the president, occupied the chair, and he was supported among others by Sir Walter Armstrong, Sir Dyce Duckworth, Dr. and Mrs. Lauder Brunton, F.R.S., Inspector-General W. H. Lloyd, R.N., Sir Christopher Nixon, Sir Philip C. Smyly, Dr. P. S. Abraham, Mr. and Mrs. Robert O'Callaghan, Dr. Gilbert Smith (chairman of Council), Dr. Joceyln Swan (hon. treasurer), and the two honorary secretaries Mr. P. J. Freyler and Dr. James Stewart. After the usual loyal toasts, the chairman proposed "Our Defenders," in which many references were made to the Irish *personnel* among the commanders of the troops now serving in South Africa. The toast was warmly received and was suitably responded to by Surgeon-Major-General Rice, C.S.I., and Staff Surgeon Barrington, R.N. "Our Guests" was next proposed by Inspector-General Lloyd, R.N., to which Sir Dyce Duckworth replied. Dr. Lauder Brunton, in a happy and well-conceived speech, gave the concluding toast, that of "Ourselves," and this was acknowledged by the President. Afterwards an "At Home" was held and was attended by upwards of 400 ladies and gentlemen, consisting of members and guests of the Association. The entertainment provided was of an exceptional description, including songs by Mr. Franklin Clive, Mr. William Nichol, and violin solos and recitations. The whole evening was a great success, and the reunion was, apparently, greatly appreciated by all present.

Surcharging of Guardians' Law Costs.

A CASE has been recently reported in which the Guardians were decreed by the County Court Judge to pay £8 for the law costs of a suit brought by the doctor to recover one guinea due to him by them, which sum he recovered. This is not the first instance by many in which the interests of the ratepayers have been sacrificed avowedly to spite the doctor, because he insisted upon his legal and moral rights, and we have before us from day to day newspaper reports which record speeches of Guardians to this effect. We should wish to ask whether, when the law is clearly against the Guardians, yet they persist on going into court with a hopeless case, and are, of course, mulcted in heavy costs, the Local Government Board considers it right that its auditors should pass such outlay as legitimate. We do not desire to limit, in the slightest degree the right of guardians to contest a claim, which may possibly be bad in law, but when the guardians have been declared by a judge to be in the wrong, and when it appears that they, or their legal advisers, should have known that

the law was against them before they forced the matter into Court, we submit that it is quite unjustifiable that a dominant clique should be allowed to mulct the ratepayers in costs for the wanton gratification of their own ill-temper. If it can be done, the auditors should be instructed to surcharge against such guardians the expense involved unless he is satisfied that the suit has been undertaken by the Guardians *bona fide*, and for the purpose of protecting the ratepayer against an illegal demand.

How Irish Poor-law Elections Are Worked.

AN inquiry has recently been held by the Local Government Board as to the circumstances attending the election of a dispensary doctor for Westport. There were two candidates, and it is needless to say that their competency or incompetency had nothing to say to the case. Had they been stone deaf, blind, or imbecile they would have been elected if they belonged to a certain politico religious party, but there was, not at all for the first time, another element in determining the result. Certain of the guardians required to be paid in hard cash for their votes. One of them wrote "several of us will take the money if you can see your way to a majority, I will be on your side for £2," and another, "It is believed that it is money that will do it all, and I know five or six that would sell their votes for very little. There is one doctor that will sport £100 on the job—it is a fact—and it is no use for him. He will not be returned, as no man stands a better chance than a Leaguer." It would be pleasant if we knew what the Chief Secretary thinks of this method of selection of a medical adviser for the sick poor and whether he thinks of doing anything to purify the Augean stable. We by no means expect that he will.

Penal and Disciplinary Powers.

IT is satisfactory to find that the majority of the licensing and degree-conferring bodies have at last been brought into line in respect of the proposed re-modelling of the penal and disciplinary powers which they possess in common with the General Medical Council. What the Council requires is the power to suspend registration for a definite period without going through the form of erasure of the name with subsequent reintegration thereof. The licensing and degree-conferring bodies, on the other hand, require to have the right to suspend a qualification with the power to hand back the same without obliging the delinquent to re-present himself for examination. It is manifestly absurd for the Council to have, so to speak, to don the black cap when inflicting punishment for an offence which is regarded as adequately purged by a year's suspension. It is also subversive of discipline that a man who has been struck off the *Register* should go on practising his profession as if nothing had happened, a course in which police magistrates appear to take malign pleasure in backing him up. If the diploma could be withdrawn for a time the delinquents would no longer have any pretence for continuing to practise, and magistrates

would have no option but to enforce the law. We are pleased to think that this moderate measure of reform is now within measurable distance of accomplishment, and advantage is to be taken of the opportunity thus afforded to secure that fines and penalties inflicted for contraventions of the Medical Acts shall be paid over, as of right, to the General Medical Council. The appropriation of these sums by the authorities has sadly hampered the very necessary work of stamping out certain forms of illegal practice in the past.

Reciprocity of Medical Practice.

CONSEQUENT upon the renewal of the agitation in Italy in favour of restricting medical practice to persons possessed of a native qualification, the question of reciprocity in medical practice may be said to have entered upon an acute stage. Unless advantage be taken, and that speedily, of the section of the Medical Act (1886) to establish reciprocity with Italy, it may be taken for granted that the Government of that country will be unable to withstand the pressure which is being brought to bear. Steps have been taken to define exactly the position of practitioners with foreign qualifications in this country, and we presume the next step will be for the Council to intimate to the Privy Council its wish to be authorised to recognise and admit to registration duly authenticated Italian diplomas. The question, however, is not as simple as it looks because such a departure would establish a precedent which would have to be followed in respect of other countries. The difficulty, however, is not of the magnitude which we are asked to believe, seeing that the General Medical Council will remain master of the situation, inasmuch as it has the power of admitting to registration only such diplomas as appear to offer the necessary guarantee of knowledge. We have no sympathy with the narrow views which would prevent reciprocity, merely because it might bring foreigners into direct communication with native practitioners. That is precisely the argument upon which is based the protectionist policy of most foreign governments towards British practitioners who wish to exercise their profession abroad. For one foreign practitioner who would come to practise in England, scores of British practitioners would obtain the right to practise abroad; in fact, reciprocity must of necessity be all to the advantage of British practitioners. This question should be approached from a statesman's point of view, and not in the huckstering spirit which is better suited to the small shopkeeper, and although Mr Horsley has thought fit to make himself the exponent of the views which we condemn, we prefer to believe that it was the direct representative who was speaking and not the fellow of the Royal Society. Fortunately, even should the Council yield to its conservative instincts to the extent of refusing to move in the matter, it is open to the Queen in Council to impose the recognition of Italian diplomas; but this is a contingency which we would fain hope the Council will not impose on the Government.

Senior Students as Assistants.

THE General Medical Council has done much to stamp out the unqualified assistant, but, *pari passu*, it has connived at the employment of senior medical students as assistants in medical practice. There was a delightful ambiguity about this quasi-permission which was sure to bring the Council into difficulties, an instance of which presented itself during the present session. The difficulty was surmounted on this occasion by dismissing the charge, but it will be necessary for the Council to define with some approach to precision at what period of study, and to what extent the senior student may assist a registered practitioner. Actual participation in medical practice at a period not unduly removed from the termination of the curriculum is unquestionably an invaluable means of acquiring practical knowledge, and, what is even more important, of learning how to conduct a practice, including a much neglected branch of knowledge, viz., dispensing. If such a man is to be hedged in by the rigorous restrictions imposed by the Council on the ordinary unqualified assistant, his object will be frustrated in great part, and in any event the position will be unpopular. Why should not the Council lay it down that only fifth-year students are eligible for such posts? Having done this the rules of conduct might be enlarged in order to allow of their deriving the benefit of this modified form of apprenticeship. If the matter be left in its present unsatisfactory position, the Council will have to display an irregular and illogical indulgence whenever it can be shown that the unqualified person is a *bona fide* medical student, irrespective of his grade.

The Practical Value of Sham Diplomas.

LAST week the Master of the Spectacle Makers' Company, Sir Reginald Hanson, M.P., addressing the candidates for the optical diplomas of that body, impressed upon his hearers that they should be cautious never to infringe upon the function of the ophthalmic surgeon, and that when, in eye-testing, they discovered some disease apart from refractive error, they should at once send the patient to a competent oculist. Although the suggestion of the Master is not in accord with the view of the Examiner who gave as one of his first questions the diagnosis of glaucoma, we accept his intention as honourable and straightforward, and we are sorry that it is by no means possible for his Company to give any practical effect to it. The spectacle makers are in the same position as the Pharmaceutical and the Obstetrical Societies, which protest their desire to prevent their alumni from counter-prescribing or from the illicit practice of midwifery. Once a trader is put in possession of a pretentious looking parchment certifying his capacity these societies are entirely powerless to restrain him from turning it to any use which will pay. The well-meant assurances of the Presidents of such societies are therefore quite valueless. The medical profession will have to take care of itself, and, if it can, prevent the authoritative issue of such documents, which, as

yet, it does not appear to think it worth its while to do.

Is a Homœopathic Concoction a Medicine?

OUR readers are aware that the Apothecaries' Hall of London possesses, under its Act of 1815, the power to prevent any person from practising medicine in England unless he holds a legal qualification from the Hall itself or from some other competent body. Under this authority a person has been recently prosecuted at Ashton-under-Lyne because he practised medicine, he being avowedly a homœopath. An apothecary, it has been decided, is "one who judges internal diseases by symptoms and prescribed medicines for them." As it was clear that the defendant had violated the first part of this definition, he was driven back upon the defence that the stuff which he prescribed was not "medicine." The Judge deferred his decision, and meanwhile we may ask what the thing is for which the homœopaths receive considerable sums if it is not medicine?

Then and Now: Crimea and Cape.

A WIDE gulf divides the lot of our soldiers who fought in the Crimean campaign and those who are now showing the Boers that the old British bull-dog courage is still a characteristic of the insular breed. In the first half of the century the service medical organisation, to say nothing of the more general army administration, was little short of chaos. The sufferings of the troops from wounds, want, and exposure were terrible, and called forth the noble ministrations of Florence Nightingale, who may be said to have laid the foundations of the modern military nursing. The introduction of a perfect system of base and field hospitals, and of an Army Medical Staff Corps, whereby the wounded are at once collected and medically treated, in itself constitutes an enormous advance. Then within a brief generation soldiers in the field have gained the boon of aseptic surgery, the greatest saviour of suffering and life ever introduced to mankind by the intellect of man. Commissariat has been brought up to a precision that guarantees good food, clothing, with other necessities and even comforts to our brave campaigners. Latest wonder of all, the marvellous Röntgen rays are made to penetrate the bodies of our gallant warriors with harmless beams that demonstrate the presence and location of missiles and in some cases the nature and extent of injuries. Then there are the sumptuous and perfectly equipped hospital ships sent out by the Princess of Wales and by our American "friends across the sea," besides voluntary first aid expeditions. All these and other causes incidental to the Army Medical administration render the lot of Mr. Thomas Atkins of to-day a thousand times less toilsome and terrible than that of his predecessors in the Crimea. For all that it is a shock to read of the wounded in some of the recent fights being left out all night in pouring rain. Some of the details are calculated to fill with horror the imagination even of those inured to surgical experiences. It is to be

hoped that the nation will insist on the vast sums of money that have been collected for the relief of those distressed and bereaved in the present war being immediately and freely expended. The fact that several hundreds of thousands of pounds have accumulated from the Crimean fund appears to reflect discredit upon the administration of that fund, and to show that the objects of its subscribers have been hopelessly and recklessly diverted from their purpose.

The Dublin Student Class for 1900.

THE returns of the Anatomical Committee, made up to November 25th, show a slightly decreased number of Anatomy students in the schools, 423 for this year as compared with 435 last year. For the individual schools the figures are as follows:—Trinity College 170, College of Surgeons 130, Catholic University 123. It should be kept in mind that these figures represent only the Anatomy students, and even these not accurately. The duty of the Anatomical Committee is limited to ascertaining the number of "subjects" which will probably be required in the coming session for dissection and for operative surgery. It is, therefore, chiefly the second year students who are enrolled in this return, and those entering for other courses are not counted. Moreover, it is open to a school to apply for a greater number of subjects than it wants, in order to secure an abundance of material, and it suffers no monetary loss thereby because it subsequently obtains a refund of the money paid for the redundant material. The shortage in the number of students in the Dublin school for the last year or two is attributable to the new-born severity of the conjoint preliminary examination of the Colleges which has led to the wholesale rejection of aspirants. At the recent examination more than half the candidates were sent away unsatisfied.

Medical Volunteers for the War.

THE profession has, we believe, regarded the appointment of civilians, however distinguished, to supervise the work of the Army Medical Service in South Africa with very qualified approval. In the first place it is questioned whether such supervision is at all required, implying, as it undoubtedly does, a doubt on the part of the War Office that the administrators of the Medical Department are to be depended on in emergency, a doubt which the profession at large by no means shares. Secondly, there is a feeling that the gentlemen selected are not the best for the purpose which might be found. The President of the London College, by virtue of his experience of the Franco German War, may be looked upon as an expert in medico-military organisation, and one of the others selected is recognised as an operative surgeon of much eminence, but the third, though recognisable as an advancing surgeon, has not yet attained a position to entitle him to check the work of the campaign. It is to be feared that the appointment of these, or any other outsiders, will give rise to friction with the medical authorities on the spot. We note that one or two of the

Dublin papers have sought to make an Irish grievance out of the fact that the tender of their services by certain Irish surgeons was not accepted. Of the four gentlemen named the President of the Irish College of Surgeons, who offered himself chiefly, we believe, with the purpose of demonstrating the patriotic anxiety of his College to contribute its help, was entitled to special consideration, and the late Mr. Wheeler, by virtue of his experiences in the Abyssinian campaign, would have been regarded as a useful appointment. The other candidates, if we may call them so, whose names were quoted by the newspapers, are known simply as more or less successful provincial surgeons who could scarcely be supposed to represent Irish surgery, and it is possible that they are not well pleased that their pretensions to such recognition should be dragged into prominence by injudicious journalistic friends. In any case we object to the indiscreet effort to make these appointments a question of racial jealousy. The War Office may or may not have made a wise selection, but with that selection the question of nationality ought to have, and probably has nothing whatever to do.

Unsound Tinned Milk.

THE trade in unsound tinned milk appears to be flourishing on a large scale, if one may judge from the disclosures that take place from time to time in police courts. Last week an enormous quantity of this particularly undesirable merchandise was condemned, the evidence showing that most of the tins were blown, and that the milk was in all cases unfit for food. The defendant appeared in the witness box and maintained that some of the milk was fit for confectionery and "manufacturing" purposes. It is to be presumed that in both events the pestilential stuff would ultimately be dished up in some more or less palatable form for human consumption. There were no less than 181 cases, each containing four dozen tins, and the defendant admitted that he had bought them at a price varying from sixpence to half-a-crown a case, a clear testimony in itself to the value of this precious consignment. The whole lot, which filled three vestry dust carts, was ordered to be destroyed. In view of these and kindred prosecutions it will be well for local authorities generally to bestir themselves in dealing with this danger to the public health. Not only is there the injury to the adult population involved in the consumption of such articles, but there is the special damage to the infantile population in those quarters where the cheapness of tinned milk makes it popular as a foodstuff for babies. It is to be hoped that the pathway of the tinned milk offenders will be everywhere beset with thorns.

PERSONAL.

LATEST advices from the seat of war state that Sir William MacCormac has left Durban and gone to Pietermaritzberg in order to be nearer the main body of troops sent to relieve Ladysmith.

HER MAJESTY THE QUEEN received the medical staff, together with the nurses, of the American hospital ship

Maine, at Windsor Castle on Monday, prior to their departure for the seat of war.

WE regret extremely to hear that Sir Thomas Grainger Stewart, Her Majesty's Physician-in-Ordinary for Scotland, is not making that progress towards the recovery for which his numerous friends and well-wishers hoped and is still in a somewhat anxious condition.

DR. F. W. N. HAULTAIN, F.R.C.P.E., has been appointed one of the assistant-physicians to the Royal Maternity Hospital, Edinburgh, in the place of Dr. A. H. Freeland Barbour, who has succeeded to the post of Full Physician in place of Dr. Halliday Croom, the latter having completed his term of office.

MR. ARTHUR CHANCE, Surgeon to the Mater Misericordia Hospital, Dublin, has announced his candidature for the seat on the Council of the Royal College of Surgeons vacated by the death of the late Mr. Wheeler. Mr. Chance has already served the College as a surgical examiner and as a councillor.

MR. GEORGE BROWN, direct representative for the General Medical Council, writes:—"In order to prevent misunderstanding I will thank you to permit me to state through your columns that I have resigned all connection with the editorial department of the *Medical Times and Hospital Gazette*, which journal I founded in 1872 under the title, *The Students' Journal and Hospital Gazette*."

Scotland.

[FROM OUR OWN CORRESPONDENT.]

THE NEW MEDICAL SUPERINTENDENT OF THE ROYAL INFIRMARY, EDINBURGH.—Managers of this institution proceeded last week to fill the post of medical superintendent, vacant through the untimely death of Surgeon-Major-General Lithgow. After protracted proceedings, it was announced that Colonel W. P. Warburton, M.D. Edin., I.M.S., had gained a majority of their votes. The new superintendent is an Edinburgh graduate, his M.B. C.M. degree dating from 1865, his M.D. from 1885. Colonel Warburton's services have hitherto been almost entirely administrative, a fact which augurs well for his successful conduct of the duties of his latest post, a post of considerable difficulty, calling for the exercise of much tact, and all-round *bonhomie*, tempered with discriminating resolution.

UNSEASONABLE WARMTH.—The month of November, 1899, will long be remembered in many parts of Scotland for its phenomenal warmth. In Edinburgh the mean shade temperature works out at 47.4 degs. F., or 6.5 degs. above the 135 years' mean of 40.9 degs. for the month. This value is rather above the average mean for October, as shown by the records during the 135 years. Zymotic diseases in Edinburgh have failed to show any autumnal increase; they have, rather, shown a decrease in connection with this meteorological abnormality. During the week ending November 25, only three cases of measles were notified from amongst a population of over 300,000; the total number of cases of infectious disease notified being below 40. The latter part of the month afforded evidence that a form of influenza had again become prevalent, and as so often happens when visitations of this scourge coincide with warm weather, natural or unnatural (as witness the attack during the unusually warm early months of 1896), chiefly affected the gastro-intestinal tract. Perhaps a still narrower localisation may with reason be noted, because in the majority of instances the large bowel seemed to be selected by the causal

bacillus for its habitation. Incidentally we may mention that the village of Braemar has recently suffered extensively from an influenzal epidemic, which has spared few of its inhabitants.

STUDENT NIGHTS AT THE THEATRE.—A special form of entertainment, introduced into student life some few years ago in an unofficial manner, has more recently developed in Edinburgh into a recognised and official custom. Before a student's representative council ever was, students' theatre nights were not conducive to the comfort of the non-academical members of the audience. Since then the members of the Students' Council have taken it in hand; they secure the entire gallery of the theatre patronised for the night; provide a piano, often select the singers, and act as stewards for the night. Friday evening is usually selected, for there are no lectures to be listened to next morning; the date and the locus are posted up on notice boards beforehand, and at least half-an-hour before the curtain rises, early comers in other parts of the house are entertained with a by no means unenjoyable concert, provided by the "gods," consisting mainly of would-be asculapians. Solo is followed by part song, that in turn by chorus, until the play begins. Then all is silence, celestial silence, broken only by applause, the kind of applause to which that of the Continental subsidised *claque* is as a whisper. The act ended, and the curtain down, no need for the orchestra to while away the time, the gods provide the necessary music. Altogether, experience of what a students' night at the theatre means, not that of pre-council days, but with the gallery packed with orderly occupants, among whom are not a few respectable vocalists and who together can produce a very resonant volume of sound, robust perhaps, rather than modulated, after the fashion of a Yorkshire choir at a Leeds Festival—rather induces one to select Friday nights for one's visit to the play; the intervals, often so irksome, so often passed by men in refreshing their bodies at the bar, become interesting; nay, in some instances the entertainment provided by those above makes a poor play seem doubly poor, a thin and jejune score still more jejune.

GLASGOW UNIVERSITY—MEDICAL BURSARIES.—The following results of the competitions for bursaries open to students in the Faculty of Medicine are announced:—John Macfarlane bursary for second year students (annual value about £40, tenable for three years)—Alexander Mathieson. Lorimer bursaries (annual value £19 for three years)—Peter L. Sutherland and John M. Kelly. James A. Paterson bursaries—one of £30 annually for four years—James C. Pairman; one of £15 annually for four years—Carl H. Browning. Senior Arnott Prize of £25 for an examination in Physiological Physics, open to third and fourth year students in Medicine—Robert D. Campbell. Junior Arnott Prize of about £15, open to first and second year students in Medicine for an examination in General Physics—Malcolm Hutton, M.A. Rainy bursary (£20 for two years), open to students of the third year in Medicine, for examination in Anatomy, Chemistry, Botany, Physiology, and Zoology—David Riddell.

Manchester.

[FROM OUR OWN CORRESPONDENT.]

WOMEN STUDENTS.—Manchester is slow to move, but once in action acts thoroughly. Owens College has at last agreed to admit women as medical students. Arrangements are being made for them to enter at the commencement of next winter session. Opportunities for clinical work must be found, and to this end the College authorities have approached the Board of the Royal Infirmary. Such a momentous step needs careful consideration, and the matter has been submitted to a special committee. The rapid development of the medical school makes the necessity for adequate clinical study a very urgent one. Perhaps the "mind of the woman" will do something towards solving the problem of the future of the Royal Infirmary.

MEETING OF MEDICAL ASSOCIATION.—A preliminary meeting has been held to consider the desirability of inviting the British Medical Association to Manchester. It is generally thought that at the commencement of the new century Cottonopolis should welcome the great body of medical practitioners in this country. The representatives of the local branch are about to summon a meeting of the secretaries of the various medical societies in the district, who will doubtless arrange for a fully representative meeting of all members of the association in Manchester and the immediate neighbourhood, at which the whole question will be considered.

Correspondence.

We do not hold ourselves responsible for the opinions of our correspondents.

A SAD AND URGENT CASE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I through your columns draw the attention of brother practitioners to a most sad case with which I am personally acquainted, and which is in most urgent need of some help and assistance. An Irish practitioner, for some years holding a good practice in the North of London, contracted rectal trouble, and had two operations performed upon him. This and the consequent long lying up so deteriorated the practice that he was obliged to relinquish it, his health being greatly shattered. After a time he tried to establish himself in a comparatively poor suburb, but again his health broke down, and with a young family of five children he was reduced to sheer poverty. Still, rather than abandon his wife and children to want by going again into hospital, he continued to work, often in great agony, and despite of his disease succeeded in again getting about him a new connection. Of late, however, his health has been so completely shattered, that he could not continue to do his work, and has been forced again to go into hospital. By interest some provision has been made for a few of the children, but now the insurance on his life will be sacrificed and all his furniture sold unless some help is forthcoming for him immediately. I feel certain, Sir, that you will assist by acting as treasurer for any fund that may be raised to help in this melancholy case, and I would, through your columns, ask on behalf of this poor fellow and his half-starving family some aid at the hands of his fellow practitioners. Any sum, no matter how trivial, will be accepted gratefully.

I am, Sir, yours truly,

H. MACNAUGHTON-JONES.

131, Harley Street, Cavendish Square, W.

November 29th, 1899.

THE TEMPERANCE QUESTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your leader of last week on the temperance question, you put certain questions which I hope I may be permitted to answer. The "teetotalist"—apparently the teetotaler under a new name—is asked "if his views of fermentation would extend to the making of bread, and generally to all forms of fermentation, whatever they may be." A serious answer seems hardly called for. We shall object to bread and other "forms of fermentation" when we find that bread intoxicates, or that other forms of fermentation (whatever that may mean) give rise to about one-twentieth part of the evils produced by beer and other intoxicating beverages. The writer also shows his total unacquaintance with the literature of the temperance movement, or he would never have ventured to say that "it does not appear easy to find support in the Holy Scriptures for teetotalism." We undertake to prove that both the spirit and letter of Scripture is in favour of perfect sobriety, and as alcohol lessens sobriety in direct proportion to the quantity consumed, we conclude that the less we take of such a brain-benumbing drug the better. Our

objection to alcohol is not simply because of the evils of gross drunkenness and its concomitants. We realize that alcohol is operating from the very first in weakening the highest and latest developed powers of the mind, producing progressive paralysis of the judgment and will, rendering the individual less self-controlled and more automatic, and hence a prey to any chance suggestion of evil. As we regard as the special object of education, both civil and religious, to promote temperance (i.e. self-control), we cannot see the wisdom or advantage of using, or advising the use of an agent which acts in exactly a contrary direction, undoing what we are trying to do.

With all due deference I ask the writer whether he advises the universal and habitual use of opium. I do not suppose he is so foolish. But as the consequences of the social use of alcohol are said by those who know both to be much worse than those of opium, I do not admit myself to be more foolish than he.

I think the writer is mistaken when he says that "the tendency shown by many to indulge in excess in the use of any such agents as opium or alcohol is, in the opinion of the profession, an evidence of disease." I should like to know who has ever committed himself to such a sweeping statement. It may be granted that there are some habitual (or, more usually, occasional) drunkards who have an insane impulse to drink, but by far the greater number of excessive drinkers are simply vicious and yield to the temptations of others. We have instances without number that when such people are not tempted to drink they keep sober. In our South African army at the present time there are thousands of reservists who were sent off more or less drunk through the foolish kindness of "friends" (!) but they have been sober ever since, for the very good reason that they are not allowed anything which will intoxicate them, to their own advantage, and everyone else's. When the nation is wise enough they will put an end to all intemperance in a similar way. But "that is another story." My letter is too long already, or I should deal with the assertion that beer is food as well as drink. I will only say that I have seen several cases of delirium tremens through trying to live on beer. There may be some food value left in the soluble extractive, but anyone who wanted food would prefer the barley in any shape at a penny a pound to the beer at 2s. a gallon.

I am, Sir, your truly,

J. J. RIDGE, M.D. Lond.,

Hon. Sec. British Medical Temperance Association.
Enfield, Nov. 25th, 1899.

OPERATIONS AT THE CANCER HOSPITAL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Even in the absence of a passing resort to reflection or common sense, the trifling precaution of previously ascertaining his facts would, I think, have sufficed to avert the "indignatio" of your correspondent's letter thus headed.

Every report or circular issued from the Cancer Hospital prominently states that institution to have been founded "for the treatment of the poor afflicted with cancer, tumours, or allied diseases. Where, then, are the "false pretences" he so seathingly denounces?

That, however, is a mere technicality. When we regard the question of principle, very curt reflection will show the inexpediency of drawing a too rigid line of demarcation in such matters, even as experience proves its utter impossibility. Your correspondent may, or should know that, even when traced by scientists, the boundary line between cancerous and simple "tumours" is varying and uncertain. That this is especially the case with the lesions in question, uterine myomata. That these growths are by no means rarely associated with cancerous disease, in one form or another. That they occasionally even generate a special variety almost *sui generis*.

Even if practicable would it be advantageous to the community, or even in accordance with common humanity, to act on such narrow pedantic lines as your correspondent indicates?

At any rate all "outside general practitioners" are by

no means such purists, as within the past six weeks I have twice found my beds occupied by patients admitted on the certificate of their medical attendant, with no worse ailment than the sequelæ of a neglected miscarriage! When once thus taken into the wards, how could one refuse appropriate treatment? Mr. James Hamilton has evidently not yet learnt to realise the vital service which eleemosynary hospitals in general render to the average medico, viz., the relieving him of his non-paying patients.

The total impossibility under somewhat similar circumstances of drawing this hard and fast line has evidently been felt by our neighbour, the Hospital for Consumption. I have myself casually met with cases of mitral disease, chronic bronchitis, asthma, &c., which were receiving treatment there, and I presume that most, if not all, maladies of the thorax would fall within its "sphere of influence."

Lastly, may I point out that the Cancer Hospital specially commends itself to the "outside general practitioner," on several other important grounds than the above? Among these I need only mention two. It takes all reasonable precautions to exclude any but the "deserving poor." It never exacts a single penny from its patients; and thus lies wholly free from the imputation of intercepting moneys to which the struggling outside general practitioner might lay legitimate claim.

I am, Sir, yours truly,

HERBERT SNOW.

6, Gloucester Place, Portman Square,
December 2nd, 1899.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Not long since I was surprised to see an interesting account of uterine tumours removed in the "Cancer" Hospital, though nothing cancerous had been diagnosed! Like many others, I have laboured under the delusion that special hospitals only took in special cases; but I hear it is now notorious that none of the special hospitals stick to their speciality.

May I ask what would be thought of the specialist in private practice, who would monopolise the cases of the general practitioner in addition to his own. I imagine it would soon be made too hot for him, and I consider it most unjust both to the general practitioner, and a fraud on those leaving money in their wills to a special hospital (for a special purpose) to treat all comers, as I know is the case, at least, in the out-patient department of the special hospitals in London. Surely there is quite enough special material to supply the hospitals aspiring to that name. Without defrauding the general practitioner of a great portion of his income, hard earned as it always is, the Medical Council might devote a little of the time wasted by that ornamental body in looking into the abuse of the special hospitals (so called).

I am, Sir, yours truly,

ALEXANDER DUKE, F.R.C.P.I.

Cheltenham, Dec. 2nd, 1899.

Literary Notes and Gossip.

STILL another illustrated handbook on the diseases of women is in preparation, the author being Dr. Jellet, of the Rotunda Hospital, Dublin, already well-known as the author of a "Short Practice of Midwifery." The publishers will be Messrs. J. and A. Churchill.

MR. W. E. HUGHES, whose death is announced, was one of the best-known figures in the literary and intellectual life of the Midlands. He was a devoted disciple of Herbert Spencer, and at Mason College, Birmingham, he instituted the first Spencer Society in this country.

It is now pretty generally known that English copyright does not hold good in America, unless an author prints his work in that country. A case, however, has just been decided in the High Court at Toronto, which shows that the product of an author's brains cannot be pirated in Canada so long as the Dominion remains part of the British Empire.

WE are asked to announce by the publishers, Messrs. Baillière, Tindall and Cox, that a considerable number of the new edition of Dr. Walsh's work on "The Röntgen Rays in Medical and Surgical Work," and "The X-ray Case-book," have been sent out in H.R.H. the Princess of Wales' Hospital ship for use with the Röntgen-ray apparatus in the Transvaal war.

MR. W. G. BLACK, F.R.C.S.E., has in the press a work by his Uncle, William Black, L.R.C.S.E., Surgeon H.M.S. *Chanticleer*, "Narrative of Cruises in the Mediterranean during the Greek War of Independence, 1822-1826." Official visits to various ports are described, and scenes of operations of war precedent to the naval battle of Navarino in the Morea. It will be published immediately by Messrs. Oliver and Boyd, Edinburgh.

THE *Leisure Hour* in its new dress promises to become even more popular than its previous series, which has been running consecutively for nearly half a century. It is now published in a more handy form, is full of entertaining reading to suit all but depraved tastes, has a new serial story by Sir Walter Besant of absorbing interest, and should form one of the most acceptable of magazines for the waiting-room tables of medical men.

THE fourth volume to hand of the second series of the Index-Catalogue, Surgeon-General's Office, United States Army, contains 9,682 author-titles, representing 4,133 volumes and 8,503 pamphlets. It also contains 8,828 subject-titles of separate books and pamphlets, and 8,316 titles of articles in periodicals. This great Index-Catalogue may be said to have restored to use, the medical literature of the past, and to keep us abreast of that of to-day. It is a great gift to medicine, worthy of the great Republic.

THERE is a great need for information upon the subject of the existing sanatoria for the open-air treatment of tuberculosis at the present time. The reprint, therefore, from the *West London Medical Journal*, entitled "British Sanatoria," published by Messrs. Bale, Sons, and Danielsson is very opportune and is likely to prove highly useful. The publication is fully illustrated and gives descriptions in detail of all the known sanatoria now open for the reception of patients.

THE December issue of the *Cornhill Magazine* contains many entertaining articles, which appeal to a variety of readers. "Eagles and their Prey" is one, however, which will afford interest for all. The idea that these remarkable birds attack their prey first by tearing out the victim's eyes is quite true, for witnesses to the act have recorded the same. Again, it seems that golden eagles can carry in the air as much as eight pounds, but smaller-sized eagles have been observed to reduce this weight by tearing off an animal's head, when they found that they could not carry their prey to the nest.

THE Sanitary Association of Manchester is about to issue a series of health publications, including the following:—1. "Consumption: Its Causes and how Spread," by Dr. Arthur Ransome. 2. "Ventilation and the Curative Effects of Pure Air," by Professor J. Dixon Mann. 3. "Colds and their Consequences," by Professor Dreschfeld. 4. "Personal Habits," by Professor Leech. 5. "Feeding and Care of Children," by Dr. Henry Ashby. 6. "Causes of Diarrhoea in Children and Adults," by Dr. H. R. Hutton. 7. "Food and Drink," by Dr. R. T. Williamson. 8. "Exercise and Recreation," by Mr. W. P. Montgomery. 9. "Causes and Prevention of Infectious Diseases," by Dr. R. W. Marsden. 10. "Vaccination," by Dr. J. W. Hamill.

THE following new books in medicine and allied sciences have been received during the past few days:—A translation of Thoinot's "Outlines of Bacteriology," by Mr. St. Clair Symmers (Chas. Griffin and Co.); the second and concluding volume of De Meric's "English-French and French-English Dictionary of

Medical Terms" (Baillière, Tindall, and Cox); "The X-ray Case-Book," by Dr. Walsh (Baillière, Tindall, and Cox); "Wellcome's Medical Diary for 1900" (Burroughs, Wellcome and Co.); the late Prof. Charteris's "Practice of Medicine," eighth edition, revised by his son Mr. F. J. Charteris (J. and A. Churchill); Part II. of Cheyne and Burghard's "Manual of Surgical Treatment" (Longmans Green and Co.); Tillman's "Descriptive General Chemistry" (Chapman and Hall); "Medical Annual Synoptical Index, 1887 to 1898 (Bristol: John Wright and Co.); Vols. I. and II. of Stonham's "Manual of Surgery" (Macmillan and Co.); and "Renal Cases and Surgical Studies," by Dr. D. Newman (Jas. Maclehose and Sons).

Medical News.

The Chelsea Hospital for Women.

THE Chairman of the hospital, Lord Gienesk, held a reception at the hospital last week of the members of the committees and friends who had interested themselves in the important alterations which have recently been carried out, including an enlarged operating theatre and new sterilising and anæsthetic rooms, new hot water service, installation of electric light, electric lift. In a brief statement of what had been done he referred to the greatly increased number of patients and consequent growing demands made on the resources of the hospital as necessitating the perfect working of all departments connected with the treatment of the patients in order to maintain the excellent results which had attended the skill of the medical staff. The extremely low rate of mortality, of little more than 1 per cent., had for some time past been a feature of the statistics. Some of the patients themselves had voluntarily come forward with small contributions towards the work by which their successors were to benefit, and the generous gift of wealthier friends, like the late Baroness de Hirsch Gerenth and Mrs. Singleton, had provided half the £3,000 required to defray the cost, and Mr. Passmore Edwards, with his wonted generosity, had just given them a donation of 100 guineas. On the invitation of the Chairman the visitors then inspected the wards and operating theatre, and great satisfaction was expressed with the thorough manner in which the work been carried out.

Death Under Chloroform.

AN inquest was held at Kidderminster on the 30th ult., on the body of William Lloyd, aged 12, who died while under chloroform at the infirmary. Dr. Stretton said it was one of the unaccountable cases of heart failure from chloroform. All the organs of the body were healthy. The operation was for infantile hernia. The jury returned a verdict that death was due to misadventure, and that no blame attached to anyone.

St. Thomas's Hospital.

THE following gentlemen have been selected as House Officers from Tuesday, Dec. 5th, 1899:—House Physicians: F. H. Ellis, B.A., M.B., B.C., Cantab., L.R.C.P., M.R.C.S.; A. H. Greg, B.A., M.B., B.C., Cantab., L.R.C.P., M.R.C.S. (Extension); A. Bevan, L.R.C.P., M.R.C.S. (Extension); B. F. Howlett, L.R.C.P., M.R.C.S. Assistant House Physicians: H. R. Beale, L.R.C.P., M.R.C.S.; L. S. Dudgeon, L.R.C.P., M.R.C.S. House Surgeons: H. J. Phillips, L.R.C.P., M.R.C.S., P. W. G. Sargent, M.A., M.B., B.C., Cantab., L.R.C.P., M.R.C.S., S. A. Lucas, L.R.C.P., M.R.C.S., H. T. D. Acland, L.R.C.P., M.R.C.S. (Extension). Assistant House Surgeons: A. Webb Jones, L.R.C.P., M.R.C.S.; E. A. Gates, L.R.C.P., M.R.C.S.; E. C. Bourdas, L.R.C.P., M.R.C.S.; N. Unsworth, L.R.C.P., M.R.C.S. (Extension). Obstetric House Physicians: Senior—G. B. Thwaites, M.B.Lond., L.R.C.P., M.R.C.S.; Junior—H. H. R. Clarke, L.R.C.P., M.R.C.S. Clinical Assistants: Throat—A. J. B. Adams, L.R.C.P., M.R.C.S.; S. H. Belfrage, M.D.Lond.; Skin—T. Perrin, L.R.C.P., M.R.C.S. (Extension); Y. Takaki, L.R.C.P., M.R.C.S.; Ear—Y. Takaki, L.R.C.P., M.R.C.S. Electrical Department: E. F. Buzzard, M.A., M.B., B.Ch.Oxon., M.R.C.P. Lond.

Notices to Correspondents, Short Letters, &c.

✍ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

WEARY OF NOURISHMENT!

THE little maid had been ill and had struggled through the early stages of convalescence. She had taken "nourishing" broths and "nourishing" jellies until her soul was weary within her. One morning she electrified the family by sitting bolt upright in bed and saying: "I want you all to take notice, I am not going to take any more nourishment. I am hungry and I want my meals, and not another mouthful of nourishment will I take."—*Medical Brief.*

Dr. D. W. is thanked for the information, which will be utilised in due course.

A CYCLIST'S DIAGNOSIS.

THE scorchers, who thought of nothing but his bicycle caught a cold which left him with a very sore throat. He decided to see a physician. "Well," said the doctor, cheerily, "what seems to be the matter?" "I can't say exactly," was the reply, in a heavy whisper, "but it feels and sounds as if I had a puncture in my inner tube!"

ESMOND.—We can only sympathise with our correspondent. He might submit the facts of the case to his legal adviser, but we fear there would be no grounds for redress.

LONSDALE B.—Garrulosity in a patient, whether old or young, is not necessarily an indication of anything more serious than eccentricity.

HOUSE SURGEON.—No fees are recoverable, and no legal claim can be made.

DR. BERDOE and Mr. STRATTON.—Your letters are unavoidably omitted for want of space.

BRASS SCREW SWALLOWED BY AN INFANT.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR.—An interesting notice under above heading appeared in one of your contemporaries last week, in which it was stated an infant of fifteen months swallowed, and subsequently safely passed, a screw of considerable size, the wonder being the child showed "no symptoms of discomfort" after screw had reached the stomach! I should have thought any young child having swallowed a screw (over an inch in length, judging by illustration) must have suffered excruciating pain. However, the sequel shows the screw was safely passed on the fifth day "without any difficulty," fortunately detected, may we add, by the close scrutiny of the nurse or attendants.

Query. What was the nature of food given to child which acted so well as a screw propeller?

I am, Sir, yours truly,
INTERESTED.

Meetings of the Societies and Lectures

WEDNESDAY, DECEMBER 6TH.

OBSTETRICAL SOCIETY OF LONDON.—8 p.m. Specimens will be shown by the President, Dr. Blacker, Dr. Tate, Dr. Spencer, Dr. Robinson, Dr. C. Keep, and Dr. J. Phillips. Paper:—Dr. J. Phillips: On a Case of Acute (?) Idiopathic Peritonitis complicating Pregnancy and Labour.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL (Gray's Inn Road, W.C.).—8 p.m. Clinical Evening. Dr. P. Jakins: Demonstration of Cases of Operation on the Mastoid Process, Cerebrum and Cerebellum for Post-Otitic Suppuration.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—4.30 p.m. Dr. T. D. Savill: Herpes and other Dermato-Neuroses. (Post-Graduate Course.)

THURSDAY, DECEMBER 7TH.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road).—8.30 p.m. Prof. Watson Cheyne: Surgical Tuberculous Diseases. (Harveian Lectures No. 1.)

NEUROLOGICAL SOCIETY OF LONDON (11, Chandos Street, W.).—8.30 p.m. Dr. F. E. Batten and Dr. J. S. Collier: Spinal Cord Changes in Cases of Cerebral Tumour. Dr. W. J. Harrison: An Experimental Investigation on the Decussation of the Optic Nerves in various Animals, and on the Path of the Reflex for the Contraction of the Pupil to Light (Meynert's Fibres). Dr. Mott and Mr. A. F. Tredgold: Hemiatrophy of the Brain and its Effects upon the Spinal Cord. Each paper will be illustrated by lantern slides and microscopic specimens.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL (Gray's Inn Road).—5 p.m. Dr. D. Grant: Treatment of New Growths in the Nose and Nasopharynx.

FRIDAY, DECEMBER 8TH.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich Road, S.E.).—8.45 p.m. Mr. Victor Horsley: The Treatment of Trigeminal Neuralgia (illustrated by lantern views). (Purvis Oration.) Followed by a Conversation.

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8.30 p.m. Papers: Mr. A. E. Barker: Remarks on Twelve Cases of Perforating Gastric Ulcer treated by Operation. Mr. J. Hutchinson, jun.: Two Cases of Successful Primary Resection of Gangrenous Small Intestine. Dr. A. F. Voelcker: A Case of Arrested Development of the Speech Centre.

Vacancies.

Fisherton House Asylum.—Assistant Medical Officer. Salary £150 per annum, with board, lodging and washing. Apply to Dr. Finch, the City House, Salisbury.

Guest Hospital, Dudley.—Senior Resident Medical Officer. Salary commencing £100 per annum, with board, residence, attendance, and washing.

Lincoln Lunatic Hospital.—Assistant Medical Officer. Salary £100, with board and washing.

Middlesex Hospital, W.—Assistant to the Cancer Research Laboratories. Salary £100 per annum, with an increment of £50 after his second year of office if re-elected. Also Medical Officer and Registrar to the Cancer Department. Salary £100 per annum, with board and residence in the College.

Norfolk and Norwich Hospital, Norwich.—House Physician for two years, unmarried. Salary £80 a year, with board, lodging and washing.

North Staffordshire Infirmary and Eye Hospital, Hartshill, Stoke-on-Trent.—House Governor and Secretary. Salary £300 a year, non-resident.

Pontefract General Dispensary and Infirmary.—Resident Medical Officer. Commencing salary £150 per annum, with furnished rooms, fire, lights, and attendance.

Queen's County Infirmary.—Medical Officer. Salary £182 6s. 2d. per annum. Applications to Geo. Dimond, Secretary. (See advt.)

South Devon and East Cornwall Hospital, Plymouth.—House Surgeon. Salary £100, with board and residence.

Three Counties Asylum.—Second Assistant Medical Officer. Salary commencing at £150 per annum, with board, apartments, washing. Applications to the Clerk, St. Neots, Hunts.

University of Edinburgh.—Additional Examinerships in Materia Medica and Clinical Surgery. Salary of the Examiner in Materia Medica £75 per annum, and that of each of the Examiners in Clinical Surgery, £50 per annum.

Victoria Infirmary of Glasgow.—Superintendent and Resident Medical Officer. Salary £300 per annum, with board in the Infirmary and a free house.

Appointments.

BLOXAM, G. E., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Western Dispensary, Bath.

BRAITHWAITE, JAMES, M.D.Lond., M.R.C.S., Consulting Obstetric Physician to the Leeds Infirmary.

COASE, JAMES, L.R.C.P.Ed., L.R.C.S., Visiting Surgeon to the District Hospital, Beechworth, Victoria, Australia.

CONNAL, JAMES GALBRAITH, M.B., Lecturer on Auril Surgery in Anderson's College Medical School, Glasgow.

CROSTHWAITE, W. S., L.R.C.S., L.R.C.P.Irel., Civilian Surgeon by the War Office on the hospital ship 'Princess of Wales' proceeding to Cape Town.

FARMER, W. H., M.R.C.S., L.R.C.P., Civilian Surgeon by the War Office on the hospital ship 'Princess of Wales' proceeding to Cape Town.

HARDY, L. E., M.B., C.M.Edin., Civilian Surgeon by the War Office on the hospital ship 'Princess of Wales' proceeding to Cape Town.

HOPKINS, J. J., L.R.C.P., L.R.C.S., Medical Officer for the Castlebar No. 1 Dispensary District.

KELYNACK, T. N., M.D., M.R.C.P., Assistant to the Professor of Medicine at Owens College, Victoria University.

PHILLIPS, J. H. D., B.A.Oxon., M.R.C.S., L.R.C.P., House Surgeon to the Buenos Ayres British Hospital.

ROUSE, R. D., L.R.C.P.Lond., M.R.C.S., Medical Officer of Health for the Madron Urban Sanitary District.

RYAN, PERCIVAL CECIL HARDINGE, M.A., M.D., B.Ch.Dubl., Public Vaccinator for the city parishes of Bath.

TAYLOR, FRANK E., M.A., M.Sc., M.B., B.Ch., Senior Resident Medical Officer to Queen Charlotte's Lying-in Hospital, London.

WARBURTON, Colonel W. P., M.D.Ed., Superintendent to the Royal Infirmary, Edinburgh.

WILLIAMSON, B. T., M.D.Lond., M.R.C.P., Assistant Lecturer in Medicine at Owens College, Manchester.

Births.

ABERNETHY.—On Dec. 1st, at 10, St. Colme Street, Edinburgh, the wife of Robert Abernethy, M.D., F.R.C.P.E., of a daughter.

HEDGES.—On Nov. 28th, at Newport, Salop, the wife of C. E. Hedges, M.D.Cantab., of a daughter.

KATTRAY.—On Nov. 30th, at 17, Pemberton Gardens, London, N., the wife of P. Whyte Kattray, F.R.C.S., of a daughter.

SENIOR.—On Nov. 29th, at Herne Bay, the wife of E. W. Senior, M.B.C.S., L.R.C.P., of a son.

Marriages.

REID-BARING.—On Nov. 28th, at St. Paul's, Knightsbridge, Sir James Reid, Bart., M.D., K.C.B., Physician in Ordinary to the Queen and to the Prince of Wales, to Susan, daughter of the late Lord Revelstoke.

Deaths.

COOPER.—On Nov. 28th, at his residence, King Street, Leicester, Charles William Cooper, M.B., aged 57 years.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

VOL. CXIX.

WEDNESDAY, DECEMBER 13, 1899.

No. 24.

Clinical Lecture ON INTERLOBAL PLEURISY.

DELIVERED AT THE HÔTEL DIEU.

By PROFESSOR DIEULAFOY,

Of the Paris Faculty of Medicine.

THE patient I am going to present to you to-day will furnish us an opportunity of studying interlobal pleurisy. But first of all let us define what is meant by interlobal pleurisy. It is pleurisy which develops and becomes encysted between two lobes of the lung. The lungs, as you know, are divided into several lobes, two for the left lung and three for the right. Examine a lung removed from the thorax and you will see that its surface is indented with fissures which penetrate right to the hilus, dividing the lung into distinct lobes. The visceral pleura enters these fissures and clothes their surfaces corresponding to the lobes of the lung; it is for that reason that it is called interlobal pleura. When adhesions close the lips of an interlobal fissure, the interlobal pleura no longer communicates with the large pleural cavity, and a pleural sac is the result, favouring the development of encysted pleurisy. This pleurisy, hidden in the recesses of the lung is almost always purulent, as was noticed by Laennec long ago.

Interlobal pleurisy can extend a considerable distance occupying a whole interlobal space; in such cases the neighbouring lobes are strongly compressed and the liquid attains a quart or more. At other times, on the contrary, adhesions circumscribe the cavity, and the purulent liquid imprisoned in this limited space does not exceed eight ounces. The topography of the interlobal pleurisy is in itself very variable. The liquid is not always confined to the horizontal fissure at the back of the thorax; it occupies sometimes the axilla in the region of the oblique fissure, and may descend to the base of the chest. Do not suppose that the anatomical and normal situation of the interlobal fissures is of great help in the exact localisation of the pleurisy, for the relations of the fissures are singularly modified by the effusions and by the retraction of the lobes of the lung. Consequently, the pathological topography does not always correspond with the normal topography. These general notions laid down, I will proceed to discuss the clinical aspect of the question.

The man before you, now in perfect health, entered the ward in the first days of October. On his arrival we were struck by his facies and his almost cachectic aspect. He had considerable dyspnoea but no fever.

His history was as follows:—Enjoying usually good health, he was suddenly exposed in a moment of profuse perspiration, to a draught on September 25th, while washing the yard of the house where he was a janitor. He dined without appetite, complained of rigors, and passed a restless night. The following day he felt better, but on the third day

the shiverings returned with fever and pains in his limbs. Towards nine o'clock that evening he complained of acute pain in the left side, which no rubbing allayed. An incessant dry cough set in with fever. A doctor called in diagnosed pulmonary congestion with commencement of pleurisy in the left side, and prescribed a blister and a sedative mixture. The following days the pain and the cough persisted, expectoration was insignificant, prostration was marked, and the general condition bad. After a week or so the patient complained of a bad taste in his mouth, and his wife remarked that his breath had a foetid odour. A vomica was doubtless in preparation. From that moment the man's condition grew worse, the weakness increased, profuse sweating took place at night, the cough became more and more frequent, and whatever expectoration there was had a foetid odour. It was under these conditions that he entered the hospital. Close examination showed that the left side of the thorax was affected, principally behind, towards its inferior two thirds, the lesion also extended towards the axilla and to the anterior thoracic region. Here and there were found râles and a souffle as if congestion was present, while percussion revealed a zone of dullness extending from the fifth to the eighth intercostal space behind, and continued up to the axilla. Above and below this dullness percussion gave tolerable resonance. Vocal fremitus, absent over the seat of dullness, was present everywhere else. On auscultating the patient no vesicular murmur, souffle, ægophony nor bronchophony could be perceived over the dullness. Higher up sibilant and mucous râles were heard. A diagnosis had to be made. What was this acute thoracic, unilateral affection, with a dull and silent zone surrounded by râles and a souffle, with foetid breath and expectoration? Was it a case of pneumonia terminating in abscess or by gangrene, or was it an encysted pleurisy tending to a vomica? To pronounce in favour of pneumonia, with abscess and vomica, the initial phase of that affection was wanting. The patient, as we learned from his history, had not the rusty sputa of pneumonia, nor was the cough followed by expectoration of any kind: further auscultation ought to have revealed to us many other signs; exaggeration of vocal fremitus, bronchophony, bronchial souffle, &c. Nothing of all that could be found. It was consequently very probable that we had to do with an encysted pleurisy, which commenced to open into the bronchi under the form of foetid expectoration.

The patient was put under a régime of expectancy until a decision could be arrived at. The following days the temperature rose to 104 degs. F., the dyspnoea increased, and the expectoration did not cease to be foetid. On October 13th the man was seized with violent fits of coughing, during which he expelled a large quantity of purulent matter, the smell of which was so offensive as to fill the ward and incommode the other patients. Immediately a change occurred in the signs furnished by a usulta-

tion; the silent zone was replaced by a zone of soft souffle, confirming thus the diagnosis; the patient had emptied through the bronchii an interlobar pleurisy. I waited a few days before interfering, in the hope of a spontaneous cure, but no improvement took place in the condition of the patient. The foetid expectoration continued, as well as the night sweats, and the man was still losing strength. Under these circumstances I decided to wait no longer, and on October 20th, or eleven days after the man entered the hospital, I handed him over to my colleague of the surgical ward, who immediately proceeded to open largely the seat of the infection. An incision was made from the external border of the scapula to the fifth rib, and then obliquely down and outwards to the axilla. The costal periosteum was detached in the usual manner, and two inches and a half of the sixth rib removed. Through the window thus made the pleura appeared adherent, thickened and of whitish colour. The blade of the scalpel was passed in, and gave exit to a quantity of foetid pus indicating that the seat of the abscess had been reached. The operator passed his finger into the aperture and assured himself that the cavity was clearly limited above and below, and was prolonged to the hilus of the lung in the direction of the interlobar fissure. After placing two drainage tubes in position, the wound was sutured; no syringing out was deemed necessary. The day following the operation, the man's condition had already considerably improved, and each day the symptoms got better, so that at the end of a fortnight he was sent back to us as convalescent, and to-day, or six weeks after the operation, I present him to you in perfect health.

Let us now pass to another case of the highest interest. On July 5th I was called by Dr. Carron de la Carrière to a child of ten-and-a-half, on the fourth day of her illness. The girl had been seized with a pain in the left side, with difficulty of breathing and high fever. When we saw the patient on the third day of her malady it was really impossible to form an exact diagnosis. The pain in the side had decreased, the breathing was laboured, the cough gave no special indication, expectoration was absent, although she knew how to expectorate; the fever ran high, and pulse was very quick. percussion revealed a loss of resonance behind, and at the left in the region of middle third of the thorax, while auscultation showed in the same region a souffle and a few disseminated rales. This souffle was not tubal nor muffled. There was consequently no absolute sign of pneumonia or of pleural effusion; the rales were few, subcrepitant, with some friction sounds over the affected zone. The right lung was entirely free, while the same could be said of the heart, as well as all the other organs. It was certainly not a case of pneumonia, nor could we be sure that there was pleural effusion; the lesion presented all the signs of pulmonary congestion, with more or less involvement of the pleura. Consequently the diagnosis of pleuro-pneumonia seemed justified. M. Jules Simon, who had seen the patient the previous evening, came to the same conclusion. For some days the condition remained unchanged: the fever remained high, oscillating between 102 and 104 degs. F. The dullness covered a larger surface, the souffle and the rales maintained their primary character. However, a new sign attracted our attention, the heart was somewhat displaced towards the right as frequently occurs in pleural effusions of the left side. Nevertheless, we could discover no certain sign of pleurisy, agophomy, pectoriloquy, and aphonia were absent, while the dullness was incomplete, and the thoracic vibrations were clearly felt. The general state of the patient was satisfactory enough. The cough was moderate, the nights fairly good, but

respiration was forty to the minute. We were now at the eleventh day of the malady and nothing announced an abatement in the symptoms; not only did the hoped for defervescence not arrive, but the temperature attained and exceeded in the evening 104 degs. F., and we even suspected tuberculous infection. The right side of the chest remained free from lesion. The following day, however, the signs became somewhat modified; the dullness disappeared along the spine and at the base of the thorax, whilst it revealed itself under the form of a dull zone in the axilla and the anterior portion of the thorax; the displacement of the heart was more pronounced, and it could be felt beating on the right of the sternum; the resonance of the space of Traub maintained its integrity. The idea of purulent pleurisy came into our minds, and we asked ourselves if it might not be a case of pleurisy of the whole cavity, or limited to the lobar fissure. The walls of the thorax did not present the slightest edema, but the violence and persistence of the fever were for us an indication of suppuration, and we acquainted the parents with our conclusions, and the necessity of making an exploratory puncture so as to be fixed on the nature of the process. It was at this moment that the mother remarked to us that the child's breath was very foetid, a precursory sign of a vomica, and we immediately concluded that the case was one of intralobar pleurisy. The following day a consultation took place, and while we were preparing in another room the instruments to tap the abscess, the patient was seized with a violent fit of coughing and brought up some very foetid matter which the mother brought to us in a handkerchief; it was the commencement of a vomica. We postponed our intervention until the following day, hoping, as has frequently occurred, for a spontaneous cure of the vomica. But the fever was in no way abated, and the general condition having in no wise improved, although during the night about six ounces of pus were expectorated, we decided on delaying no longer, and M. Tuffier, who was invited to join us, proceeded to resect the fourth rib for about an inch: the pleura was found thickened and adherent, and when the canula was pushed in about eight ounces of exceedingly foetid pus spurted out. There was no longer any doubt about the case; it was one of intralobar pleurisy; the finger passed in through the wound could feel the superior and inferior lobe; the pleurisy occupied the entire fissure even to the mediastinum, thus explaining the displacement of the heart to the right of the sternum. The case of this little patient, examined day by day, I might also say hour by hour, shows you how difficult is the diagnosis of interlobar pleurisy. At the outset, nothing precise; during several days, signs and symptoms vague and uncertain. I will insist more particularly on this point by-and-bye, when tracing the *debut* and the evolution of intralobar pleurisy. After the operation the cavity was filled with sterilised gauze, and the following day the temperature fell to the normal, and recovery was uninterrupted. After citing several other cases borrowed from different authors, Prof. Dieu said: "Intralobar purulent pleurisy, like purulent pleurisy of the entire cavity, may be primary or secondary; it is called secondary when it is consecutive to pneumonia (metapneumonic). But although the fact may appear paradoxical, I am of the opinion that the affection is usually primary."

Nothing is more difficult to recognise than the *debut* of intralobar pleurisy. The pain in the side, the fever, the cough, indicate naturally an acute thoracic affection, but when the question arises to decide the nature and the seat of this thoracic affection you have no precise sign to guide you. Is it a case of pneumonia? The rigor, the crepitant rales, the souffle, the rusty expectora-

tion, clear up the diagnosis at once. Is it a pleurisy? The signs of effusion—dullness, absence of thoracic vibrations, ægophony, &c., tell you that you are assisting at the evolution of pleurisy, but quite other is the *début* of interlobal pleurisy. The infection constituting this encysted pleurisy might be compared to an infection of a closed cavity, adhesions having suppressed all communication with the great pleural cavity. During the first two or three days of the encysted pleurisy examine with care your patient by percussion and auscultation, and what will you find? You will find either behind or in the axilla, in a region of uncertain limit, dullness, râles, souffle, in other words, pulmonary and not pleural signs. Nothing at the other side of the chest; the lesion is unilateral. Impossible at this period to make a satisfactory diagnosis, and you prescribe according to the urgency of the case, dry or wet cupping, quinine, antipyrine, sedative mixture, and you wait. The following days the same uncertainty, the same insufficiency of signs furnished by examination of the chest: the pain in the side is perhaps less acute, the cough less violent, expectoration nil or of no account, fever high, dyspnoea intense, the time passes and you have not yet made your diagnosis. You have pronounced it to be a case of pleuro-pneumonia, and yet you are beginning to fear the presence of tuberculous infection. It is thus that you arrive at the tenth or twelfth day of the malady and still deference has not set in. At this point the tableau is about to change. If the quantity of liquid accumulated in the intralobal fissure is sufficiently large, a pint in the adult, eight ounces in the child, you perceive either behind, or in the axilla a zone of dullness corresponding to the fissure. If the liquid occupies the oblique fissure of the left side, a considerable displacement of the heart towards the right side is the result, as we have seen in the case of the little girl. Then the idea of encysted pleurisy gains ground in your mind. Percussion limits the dull zone, either to the middle third of the thorax, or to the region of the axilla. You make your diagnosis, and pronounce the case to be one of encysted pleurisy.

Among the possible symptoms of encysted pleurisy there are two to which I particularly desire to call your attention. Hæmoptysis has been several times remarked in the course of encysted pleurisy. This hæmoptysis was particularly described by Pailhas in his thesis (1889). The first idea, when it occurs in a pleurisy patient with fever and purulent expectoration, is that the man is tuberculous. but such an interpretation would be erroneous. Numerous are the cases of encysted pleurisy in which hæmoptysis took place, either before or after the formation of a vomica, which is the second symptom I alluded to. In a general way, the opening of an abscess into the bronchi is much more frequent in encysted pleurisy, than in purulent pleurisy of the great pleural cavity, which lasts months and years without ending in a vomica.

I have been able to predict several times the vomica twenty-four and thirty-six hours in advance, thanks to a sign which I described long ago, and that is *fœtid* breath. The liquid of encysted pleurisy is almost always fœtid. Long before the opening of the abscess into the bronchi is large enough to give passage to the us of the vomica, small cracks occur, through which escapes the fœtid emanations of the cavity. Do not forget this sign; it will permit you to foretell the vomica, and aid you in your diagnosis.

I arrive now at the treatment of encysted pleurisy. I may say at the outset that the medical treatment is nil. You are in presence of an infected cavity filled with liquid, which must be evacuated. In fortunate cases, the vomica operates the evacuation

alone, and in a few weeks all the symptoms disappear, and spontaneous cure is obtained. But if the fever persists, if the symptoms of infection become accentuated, do not wait. Advise surgical intervention, and if the operation is done in time, and according to the rules of the art, success is certain. Of the eight patients whose history I traced before you, six were cured by operation; the other two were not operated upon and died.

A CASE OF SUPPURATING PELVIC CELLULITIS:

WITH SOME REMARKS ON THE OCCURRENCE OF LOW OR SUBNORMAL TEMPERATURES. (a)

By A. RABAGLIATI,

Honorary Gynecologist, Bradford Royal Infirmary.

THE following case of suppurating pelvic cellulitis, faecal fistula and (as the event showed many months afterwards) of undiagnosed accompanying suppurative salpingitis is exceedingly interesting. I showed the specimen, as some members may remember, at our last meeting but one last year, and proceed to describe the case now. Perhaps some may recollect that I showed an opening in the ileum which was glued up to the abdominal wall in the right ileo-inguinal region. I showed also a fistulous tract which had dissected its way down behind the pubic ramus, and between that and the bladder; and I showed lastly an empty sac which was the right salpinx, and which, at the post-mortem examination, had been about the size of a hen's egg, and had been full of stinking pus.

The account of the case is as follows:—Mrs. H. M., æt. 27, became in-patient in the Bradford Royal Infirmary, December 7th, 1897. It will perhaps save time if I say here also that after being discharged cured, as we thought, or nearly so, on March 5th, 1898, she came in again on March 14th, 1899, about a year after, on account of recurring suppuration in the right ileo-inguinal region, and that she died of influenza on April 11th, 1899, four weeks after admission for the second time.

Condition on admission.—Patient complained of almost constant pain in the abdomen, all over, but perhaps more in right ileo-inguinal region than elsewhere; she had pain in back, thirst, anorexia and constipation. The abdomen was somewhat distended, generally tender, but especially in right iliac, in hypogastric and in left iliac regions. Resistance to palpation in right iliac region just above Poupart's ligament, and following its direction. Percussion note dull over it for about one inch above Poupart; clear tympanic note over rest of abdomen. Pulse, 112 to 120; temperature, about 101.5 degs. F.

Previous History.—Had suffered generally from constipation of bowels. She told us that from the age of fifteen years, when the catamenia began, she had suffered from pain before, during, and after the periods, and that the pain had been much worse during the four or five months previous to admission. For last few days had had pain on micturition, and during last three days had perspired a good deal. No vaginal discharge. Last catamenial period rather more than a week ago. Married two and a-half years. No children; no miscarriage. Patient stated that she had had an operation sixteen weeks before, of what nature she did not know, but that no anæsthetic had been administered. Five weeks

(a) Read before the Bradford Medico-Chirurgical Soc., Nov. 21st, 1899.

before admission she had had an attack of influenza (she died of another attack). She then had headache and backache, and felt chilly and had pain in the lower part of the back and the lower limbs. Ordered linseed poultices to abdomen. Urine 1025 clear, acid; no albumen; no glucose.

December 9th, 1897.—Dulness and resistance have extended, reaching $2\frac{1}{2}$ inches above line of Poupart. Less abdominal pain; frequent painful micturition. Sol. magnes. sulphate one in two, $\frac{5}{8}$ in hot water.

10th.—Bowels open three times. (The aperient effect of the medicine is one of the points to be relied on as assisting us to distinguish between a diagnosis of peri-typhlitic abscess and pelvic cellulitis, for should we not expect more vomiting and quasi-obstruction in perityphilitis?)

11th.—A hypodermic needle was inserted into the swelling and brought away some drops of stinking pus. Accordingly at 4.15 p.m. same day, under ether, an incision about $1\frac{1}{2}$ inch long was made above right Poupart's ligament, a little to outside of pubic spine. The muscles were dissected through; the finger being inserted felt the fluctuating sac, and a hollow needle being used as a guide, the knife was driven into the swelling, when a large quantity of offensive pus escaped. A non-perforated rubber drainage tube was passed into the cavity after it had been syringed out with boric lotion. Gauze, wool, and a many-tailed bandage completed the dressing. On being dressed on the 11th some jelly-like straw-coloured fluid (mucus) appeared in some quantity at wound.

12th.—Discharge like fæces escaped from the wound. Abdomen not distended; no pain or tenderness, no vomiting, temperature 100 degs.; no higher than usual level since admission.

13th.—Fæces and flatus passed from wound. The tube was removed, and as it was impossible to re-introduce it a smaller one was inserted. Patient feels well.

14th.—Ordinary diet; patient going on well.

16th.—Wound quite open. Large cavity discharging abundant fæcal matter. General condition satisfactory. No abdominal pain, no tenderness, no vomiting.

24th.—Tube left out. Rectum full of soft fæces. To have glycerine suppository night and morning in the hope of causing bowel to resume its natural function.

January 2nd, 1898.—Patient feels comfortable. Discharge much less. Wound dressed. Opening much smaller. Discharge, such as it is, still fæcal. Temperature, 98.8 degs. F. After this time till about January 20th patient seemed to improve. The discharge diminished, pain disappeared, temperature was natural or only slightly elevated in the evenings, tending to sub-normal in the mornings. About January 20th, when wound seemed to be closing, and there was only a faint trace of discharge at the wound mouth, patient began to complain of pain in right thigh, which crossed, she said, the upper part of the thigh to the outer side from region of sinus, and passed thence down outer side of thigh to knee. After the thigh had been rubbed with liniment sapo. co. night and morning for some days without benefit, a linseed poultice on January 26th, 1898, was ordered to be applied to the right groin for two hours night and morning.

27th.—Pain passes from region of sinus to outer side of thigh, passing thence to right knee. On examination per vaginam an elastic swelling was found in right broad ligament close to uterus. This was thought to be part of the cellulitis already diagnosed in right broad ligament.

31st.—Pain in right thigh better. Temperature normal. Wound almost healed. Poultice once daily.

February 2nd.—Complained again of a good deal of pain in right thigh, shooting down to knee.

7th.—Still a good deal of discharge from the wound. Probe passes three inches in oblique direction to right side of pelvis. Temperature normal. Pain in thigh much better.

10th.—Swelling still felt in right lateral fornix, elastic not tense. Omit poultice. Small mouth to sinus. Not much discharge.

I think I may venture here to digress in order to say that no doubt this elastic swelling in right lateral fornix was the pyosalpinx which was found at the post-mortem examination. It ought to have been diagnosed, but as we had found a pelvic cellulitis, and as discharge was still coming from the wound, I thought the elastic swelling was caused by a recurring accumulation of pus in the cellulitic abscess, and I accounted for the elastic swelling in that way. Besides, the temperature was normal and subnormal.

9th.—Morning, for instance, 97.8 degs. F.; evening, 98.8 degs. F.

10th.—Morning, 97.6 degs. F.; evening 97.0 degs. F. This ought not to have misled me, it is true; but, having my mind full of the cellulitis, I added the fact of the low temperature to the other evidence, thought the whole condition was explained by the known conditions, and missed the pyo-salpinx. This state of things emphasises a conclusion which has often before been forced on my mind, viz., that even where one finds present a sufficient and a generally recognised cause of signs and symptoms of disease, one ought still to go on examining to see if other and undiscovered causes may not be present also, especially if any unusual signs or symptoms are also found, and particularly if symptoms do not subside as they are expected to do. The presence of the elastic swelling in the right fornix might have been further investigated, and one ought not to have let inquiry be put off with a diagnosis of swelling associated with the cellulitic inflammation which was known to be present in that region. But it is easy to be wise after the event.

15th.—House surgeon's note. Probe goes three inches down sinus, and can be felt in vagina anterior to and lower than the swelling in the fornix.

21st.—Wound almost healed. A few drops of pus came away on pressure. Patient complains of no pain; feels quite well.

24th.—Comfortable. Small sinus still present with little discharge.

28th.—Wound almost healed. Feels very weak.

March 3rd.—Sinus closed, but its mouth can be opened. A probe cannot now be passed readily. It passes only one inch. Little discharge.

5th.—Patient left for Rawdon Convalescent Home.

Diagnosis.—On hearing the case read, doubts may arise in the mind as to whether the original diagnosis ought not to have been one of appendicitis rather than of suppurating pelvic cellulitis. The fæcal discharge leading to a necessary diagnosis of fæcal fistula might seem to point to suppurating appendicitis. But another explanation is, I think, the true one, viz., that the disease was really pelvic cellulitis, that this went on to suppuration, and that thinning of the exudation with pus formation had begun to take place in the direction of the bowel before I interfered and opened the abscess externally. Nature, in fact, was preparing to open the abscess into the bowel. After I had opened the abscess from the outside this thinning process still went on in the direction of the hollow viscus of the bowel, and the fistula formed. We see similar conditions elsewhere. For instance, a young lady has an abscess in the cheek, set up by a decaying tooth or teeth. On being consulted we think an effort should be made to open the abscess through the mucous mem-

brane in order to avoid an outside scar, and we open on the inside accordingly. But in the meantime, Nature had been making other preparations for opening outside, and the subcutaneous and cutaneous tissues had been thinning in preparation for the event. Although our opening inside had removed much of the outside pressure, still the process had gone on so long towards the outside, and the thinning of the outer surface of the cheek had proceeded so far that recovery at that point in the skin was impossible, and so it was that a day or two after the inner opening was made an outer one also supervened, and the opening which we had hoped to avoid in the skin still occurred. I have no doubt that an exactly analogous condition supervened in Mrs. M.'s case. Preparation had been made so long and so completely for opening the abscess into the hollow viscus of the bowel, and thinning had gone so far in that direction that even after relief to the pus was afforded outside, the opening still occurred and caused the fistulous track to form.

This same patient was readmitted in-patient, March 14th, 1899, just about a year after her discharge apparently cured. This incident makes the case somewhat long in narration. It is really two cases, but I shall be as brief as possible. Patient said that the fistulous track in the right groin had opened and closed intermittently since her discharge, and she now came in to have it cured if possible. On the 17th I opened up the track, passed a probe down for five inches to the bottom of it, and then cleared the sinus out with a Volckmann's sharp spoon, and packed with gauze, in the hope of getting the sinus to heal from the bottom. Patient went on pretty well, and seemed to be doing well till on April 2nd she complained of headache, for which phenacetine was administered. Then the temperature fell to 97 degs., but on April 4th it rose to 102 degs. Vomiting set in, and all the symptoms of what seemed an attack of influenza appeared, and on April 11th, notwithstanding all that could be done for her by the unremitting exertions of the house surgeon Dr. Chapman and the nurses, she died. The post-mortem examination showed the interesting facts already detailed.

There is another point which I wish to refer to in this case, but it is so important that I fear justice cannot be done to it at the end of a paper, and I hope indeed to take up and discuss the interesting question of subnormal temperature on an early occasion. Meantime, let me say, that on H. M.'s first stay in the hospital, her temperature throughout the month of February, 1898, was as a rule subnormal. The same was the case during her second stay in hospital before the onset of the influenza attack which carried her off. I show the chart for February, 1898, and you will see that out of fifty-six observations taken during that month on only thirteen occasions was the temperature normal or over-normal. On all the others it was subnormal, varying from 97 degs. F. to 98 degs. F. or 98.2 degs. F. Out of the thirteen observations first mentioned, nine were of a temperature of 98.4 degs., and only four were above normal. The other nine were exactly normal. But on forty-three occasions out of fifty-six when observations were taken, subnormal temperatures were registered. What is the meaning of this? It is a very common condition. The operation had been performed in December, 1897, and the track was still suppurating during the continuance of the subnormal observations of February, 1898. Not only so, but although it is almost if not quite certain that the suppurating salpingitis was present during the whole time she was under observation, still during a large part of that time the temperature was subnormal. That is to say, the presence of

a somewhat severe and serious inflammation was compatible with a subnormal temperature. The same thing occurred during her second stay in hospital when the track of the wound was still open, and when there can be no doubt whatever of the existence of the salpingitis, even if there were any as to its existence during her first stay, which I do not think there is. The first fact then which strikes us in considering the presence of subnormal temperatures in this case is that they were associated with the existence of chronic inflammation; although in inflammation, as its name implies, we generally look for the presence of hyper-normal temperatures. In fact subnormal temperatures are very common. I have seen them I do not hesitate to say in hundreds of cases, and not only so, but in very many of these cases inflammation of one or more organs was present.

The next point I shall raise is this. When do we expect to find sub-normal temperatures as a rule to be present? The answer to that question is: we expect them after a feverish attack, especially after a sharp and severe feverish attack, and whether the severe attack be of the nature of an inflammation or of a fever. At the end of a paper there is not time to discuss adequately so important a question as this, for it is really of the very utmost importance to us and to our patients, and I think we might do worse than devote a whole evening or more to this subject; but I am prepared, if members ask for them, with attempts at definitions which shall have for their object to differentiate between the two groups of pyrexial diseases, viz., inflammations and fevers proper. Let me content myself now, however, by saying that after elevated temperature, especially after greatly elevated temperature, we expect to find subnormal temperatures. After acute feverish attacks, during which the temperature is as a rule elevated and highly elevated, we expect to find, and we do generally find a period of time during which the temperature is subnormal; and after this again there is usually a slow return to normal. This is of course only a particular phase or case of the influence of the general law that action and reaction are more or less proportional to one another, not only in inorganic nature, where its influence is known and recognised, but also in respect of its action on organised structures, where its influence is not so widely recognised. High temperature in animal bodies then is apt to be followed by low temperature. There is an ambiguity about the use of the term reaction. It is usually employed of the feverish state. I am here using it in the neutral signification, and only mean that whatever is the primary state, the secondary one is the opposite of that. Now, in this case we did have the hyper-normal readings present, which were followed (and they very likely were preceded also, but I cannot go into that) by these low temperatures, to which I am drawing attention. If you will look at the chart for December, 1897, when H. M. first came into hospital, you will find the readings of high temperature, which are generally associated with the presence of fever or of acute inflammation. Through the month of January, 1898, these gradually subsided, being still, however, a little above normal, till in February, 1898, they reached the more or less permanent subnormal level. I draw this inference then from this and other cases, when we find low temperatures ruling in the organism we may generally believe that periods of high temperature have preceded them in the history of that organism. This is my second point, directly analogous to the occurrence of swelling and shrinking in the organism, viz., that low temperatures follow high temperatures as shrinking follows swelling. High temperature is not the cause of low temperature any

more than swelling is the cause of shrinking, but it tends to be its invariable consequent or sequent rather, for I wish to avoid the idea of causation and to keep to sequence or succession.

And the third conclusion I draw in this matter is this. Both high temperature and low temperature are the marks of the presence of irritation in the organism, but high temperature is the mark of irritation with intolerance (or what is commonly called reaction?) while low temperature is the mark of irritation with tolerance. Hence as childhood and youth are irritable and impatient we, seldom find low temperatures at those periods of life, but in later life, say over thirty, when the organism has become more tolerant, we find them with increasing frequency, and with still greater frequency as age advances. But if I am right in saying that irritation with tolerance causes low temperatures, while irritation with intolerance causes high temperatures, then it follows that the cause of a low temperature is the same as the cause of a high temperature. This somewhat surprising conclusion is again only a particular case of a general law which may be stated as follows, and of which very many instances can be given—viz., that the same causes acting on the organism may produce in that organism opposite states. This is, as it appears to me, one of the two great paradoxes of medicine which are intensely interesting both as regards causation and treatment, and to which as time does not allow of my discussing them at present, I may perhaps be permitted to return on a future occasion. But I may say, I think, this much, that the primary effect of all irritants is depressing or temperature-lowering or vitality-lowering, while fever, or elevation above normal or temperature-elevation or vitality-elevation is always due to the reaction of the economy from the primary depression. But when the primary depression persists, as it does in many of the izanic states, we have a low temperature prevailing, just as when the reaction comes in the cedanic condition we have a high one.

LACTATION: IN THE VIRGIN— IN THE OLD WOMAN—IN THE ADULT MALE—IN THE NEW-BORN OF EITHER SEX ("WITCHES' MILK"),

By JOHN KNOTT, M.A., M.D.,
CH.B., AND DIP. STAT. MED. (Univ. Dub.),
M.R.C.P.I., M.R.I.A.

(Concluded from page 580.)

I will now proceed to consider the existence of the mammary secretion in the new-born foetus, the "witches' milk" of the palmy days of sorcery and diabolical magic, when it was said to form part of the contents of many a witch's cauldron.

When a midwifery student at the Coombe Hospital, and under the instructive supervision of one of the most eminent obstetric surgeons of his generation, the late Dr. G. H. Kidd, I had an early opportunity of seeing the senior nurse express milk from the mammae of a newly-born male foetus. As I was surprised at the phenomenon, I made every available effort to satisfy myself on the subject, and was led to understand that the practice was general, and that the milk was almost invariably present, *especially in the male*; also that neglect of its removal was sometimes followed by inflammation and the formation of abscesses. The fact was vividly impressed on my mind soon after I commenced to practice, when I was asked by a lady friend to look after a poor protégé of hers in an approaching period of trouble. The lady

also procured a trained and certified nurse. The labour terminated without difficulty, and as the patient was a strong, healthy, and experienced woman—having previously borne a large number of children—I saw no cause for anxiety of any kind. I always inquired after the baby's health, but was confidently told that everything was as well as could be: indeed after about three days it was suggested by the patient herself that I need not "trouble myself" to come again, she felt so well, and "she knew what to do," and promised to be careful. It so happened that I was then called to the country, and was not able to return for about five days. I went to see my patient when I got back: to find her in very good condition, physically; but mentally, in a state of the most vindictive indignation towards her "grand" nurse, who had neglected to "draw the breasts" of her baby boy, with the result that one had become violently inflamed. An abscess had formed, which had been poulticed, and had opened and discharged its contents on the morning of the day of my return visit. She had actually lodged a complaint against the nurse in the institution from which the latter had been sent. This experienced mother knew all about the importance of attending to the mammae of the new-born.

Nevertheless, the knowledge of this phenomenon does not appear to have been at all generally diffused—up to, at least, the middle of the present century. Bonetus (*"Medicinæ Septentrionalis Collatitia,"* Geneva, 1684) mentions it, but apparently regarded it as a rare phenomenon in the *female* foetus. He quotes one case from Hieronymus Cardanus, and another from Joachim Camerarius—both authors of conspicuously luxuriant imagination. He adds one case of his own observation: an infant girl of two weeks old, whose nipples yielded, during a period of eight days, a fluid rivaling milk, "*liquorem lactis emulum.*" He gives no case of its occurrence in the new-born *male*. The distinguished Dr. Carpenter—one of the representative physiologists of his day—states that "a fluid which is *probably mucus* may be pressed from the nipples of many persons." In discussing the causes of abscesses of the breast of infants, Dr. Maunsell observes that "the breasts of infants, both male and female, contain at birth a secretion *somewhat resembling milk*. Accordingly, the attendants frequently set about pressing the part until inflammation and occasionally an abscess is produced."

Blumenbach in his *Institutiones Physiologicae* (trans. by Dr. Elliotson) mentions that "Occasionally . . . new-born infants of either sex . . . have been known to furnish milk," but gives no illustrative cases.

So far as I have been able to ascertain, the first systematic effort to bring existing information on the subject to a definite focus was in a communication made to the "Surgical Society of Ireland," on April 6, 1850, and published in the pages of the *MEDICAL PRESS AND CIRCULAR* on April 17 of the same year. It bears the title: "An Interesting Case of Milk in the Breasts of a Male Infant. By Francis Battersby, M.B., Surgeon to the Institution for Diseases of Children." The author, who had evidently taken great pains in the investigation of the literature of the subject states that, "I believe the common impression amongst medical men of the present day . . . is, that this secretion is not milk, but merely resembles it." The child in that case had been brought to Mr. Battersby, when aged three weeks, by a nurse who had received him from his mother eight days before. "She then found the breasts swollen and hard, and with milk in them. She obtained from them 'the least little drop,' she stated, which had the taste of milk. The breasts have since become

smaller, but are still the size of large walnuts, with the soft hardness peculiar to breasts full of milk."

For some days afterwards—the limit is not stated, as it could not be definitely observed—some milk could be pressed from the breasts in this case. The baby had been first shown to Mr. Battersby on the 3rd of the previous May, and on the 12th he reports:—"I withdrew by gentle pressure on the breasts nearly a drachm of milk. It was precisely similar in appearance to woman's milk. Having left it with Mr. Moore, I received from him the subjoined note:—

"My dear Sir,—Many thanks for the specimen of milk, which is most interesting, as it closely resembles that from the adult female. It is alkaline, throws up a cream, is not rendered viscid by caustic potash, nor does it coagulate when heated. Viewed under the microscope, it is seen to consist of normal milk globules of various sizes; on the whole, smaller than those contained in ordinary human milk, floating in a colourless fluid. It contains a few colostric bodies, and some epithelium.—Yours very truly,

WM. D. MOORE."

'F. Battersby, Esq., M.D.'"

The author of the communication here goes on to observe that: "It is to be regretted that the presence of casein was not here determined. The quantity of milk submitted to examination was so small that many experiments could not be tried, and Mr. Moore, convinced from its microscopic characters of its being milk, directed his attention to ascertain whether the colostric bodies seen under the microscope were sufficient in amount to give the fluid the chemical properties of colostrum. The fact of heat producing no coagulation, and of the fluid remaining unaltered on the addition of caustic potash, proves the absence of the colostric character. Of the fact of its having been true milk, Mr. M., from extensive observations on the subject, has not the least doubt.

"I was not again allowed to express any more milk. The breasts soon subsided, no abscess ensued, and he was growing up a healthy little child when I last saw him.

"This case is extremely interesting from its being the first in which the milk of an infant has been proved to be identical in composition with woman's milk: and the established fact of adult males, as well as male infants, secreting genuine milk, proves that the action of the uterus is not essential to that of the mamma, as is generally believed."

In the discussion which followed the reading of this communication, the principal speakers gave a very good summary of the then existing state of general public professional opinion on the subject. The remarks of three of those are well worth quoting in full—as reported:—

"Dr. Geoghegan was quite certain that in one case he had seen milk extracted from the nipple of a new-born male child, and he believed he had met it also in other instances. On the occasion referred to, he examined the supposed milk and found it to contain the oil globules and granular bodies observed in the colostrum, or first milk after parturition, but he did not submit the specimen to a chemical analysis. Nurse-tenders, who consider themselves conversant with the details of the personal care of infants, look upon the thing as by no means uncommon; and are in the habit of rubbing the swelling surrounding the nipple to facilitate the escape of the fluid.

"Dr. Darby said that within the last six months he saw a child which gave milk, or something like it, when only eight days old. The nurse-tender, who was an Englishwoman, asked him to examine the breasts of the child, and when he did so he found them in a state of inflammation. On inquiry, he discovered that the nurse was in the habit of milking the infant. He did not happen to see any of the

secretion in this case, but an abscess had formed on both breasts, produced, as he believed, from malpractice on the part of the nurse; she, however, said she deemed it a part of her duty, and that when acting as nurse-tender in England, she had always been in the habit of doing the same thing.

"Dr. Churchill said he had met with many similar cases, where inflammation, and not unfrequently abscesses, were produced in consequence of the malpractice of nurses. If the patients were let alone, and their breasts staped, the inflammation generally subsided. He looked upon Dr. Battersby's case as one of great interest, because it went far to establish the identity of the secretion of milk in the infant with that secreted by the adult female."

It is interesting, in the light of our present knowledge, to note that so high an authority on the special functions and diseases of both women and children, as Dr. Churchill, entertained, as well as did Dr. Darby, the idea that the mammary inflammation and abscess were always the result of meddlesome interference.

Another speaker on that occasion (Dr. Corbet) suggested that the substance observed by Dr. Geoghegan might have been vernix caseosa, but the objection was efficiently dealt with, by pointing out that the fluid contained both the oil globules and the peculiar bodies of ordinary milk, and in no wise resembled the vernix caseosa.

To the present writer it is peculiarly gratifying to have the opportunity of calling attention to the fact that the first appreciable advance on mediæval knowledge regarding the interesting subject of the secretion of "witches' milk" was made in Dublin; and that the first approximation to a complete chemical analysis was carried out in our city by the accomplished father of his friend, Dr. John William Moore, President of the Royal College of Physicians of Ireland.

Thanks to the better organisation of clinical observation, and the rapidly improving methods of chemical analysis, I am now able to lay before the reader a very full table of analyses of human milk both adult and infantile.

The chemical composition of (ordinary) human milk has been investigated with great care by Becquerel and Vernois, who have tabulated the following results:—

IN 1,000 PARTS.	AGE.				
	15 to 20 years.	20 to 25 years.	25 to 30 years.	30 to 35 years.	35 to 40 years.
Water ...	869.85	886.91	892.96	888.06	894.94
Solids ...	130.15	113.09	107.04	111.94	105.06
Casein ...	55.74	38.73	36.53	42.33	42.07
Albumin ...	—	—	—	—	—
Butter ...	37.38	28.21	23.48	28.64	22.33
Sugar of Milk ...	35.23	44.72	45.77	39.53	39.60
Salts ...	1.80	1.43	1.46	1.44	1.06

In contrast with the above series of analyses we can place the three subjoined ones of the milk obtained from the mammae of new-born infants:—

	QUEVENNE.	GENSER.	FAYE.
Water ...	894.00	957.05	—
Solids ...	106.00	42.95	—
Casein ...	22.00	5.57	5.60
Albumin ...	—	4.90	4.90
Butter ...	14.00	14.56	14.60
Sugar of Milk ...	62.20	9.56	9.60
Salts ...	3.40	8.26	8.30

The milk of new-born infants is stated by Beaunis to resemble colostrum: it presents a dull white or yellowish colour, and contains fat globules and granular corpuscles. The peculiarities of the small proportion of casein, and the presence of a considerable fraction of albumin, are shown in the analyses of Genser and Faye, with which, I believe, most subsequent observers agree.

The above summary will, I hope, be found to contain the most important items of our knowledge on the subject of abnormal lacteal secretion—as hitherto attained by scientific and clinical research. Illustrative cases might be multiplied in large number; but the amount of novelty would hardly compensate the reader who has carefully noted those collected in the present communication.

Clinical Records.

CASES OF CEREBRO-SPINAL DISSEMINATED SCLEROSIS. (a)

By JAMES CRAIG, M.D., F.R.C.P.

THE first, a man, æt. 34, is suffering from insular sclerosis, and displays the classical symptoms of that disease as first described by Charcot—(1) There is defective vision, o.d. $\frac{1}{2}$, o.s. $\frac{1}{4}$; the vision is not contracted; the optic papillæ have a dirty white complexion; there is nystagmus and defective power of consensual, lateral, and upward motion of the eyeballs. (2) Intention tremors are very evident. (3) Scanning speech is fairly characteristic. (4) A spastic condition of the lower extremities exists, with increased knee-jerks, rectus and ankle-clonus, weakness and rigidity of the muscles, and the "toe phenomenon" of Babinski. (5) Considerable delay precedes the act of micturition.

The next case is that of a boy, who, at the age of 9, was found to be blind of the right eye, with atrophy of the disc, which seemed to Dr. C. E. Fitzgerald to be congenital. Right eye was normal. Three years after the lower extremities became spastic, tenotomy was performed in London to correct the talipes equino-varus, and shortly afterwards the sight was lost in the right eye. Nystagmus, intention tremors, and slow monotonous speech had all developed. A probably specific origin, the youth of the patient, the completeness of the optic atrophy, and the surgical interference were the points of interest.

The third case mentioned was that of a young lady who, at the age of 17, developed symptoms of an apparently hysterical character.

In 1882 there was transient blurring, defective vision, with hazy disc in the right eye, and recovery in a month.

In 1884 left optic neuritis, with right hemiparesis, occurred, followed by recovery within a few weeks.

In 1885 there was again transient dimness of the right eye.

In 1888 there was transient blurring in both eyes, but discs were normal.

In 1889 there was transitory blurring in left eye, with vision and discs normal.

In 1890 there was numbness in right leg, weakness in both, giddiness, diplopia, blurred vision, defective lateral movement, and, for the first time, nystagmus in the left eye. Delay preceding micturition, with excessive secretion of urine, was noted.

In 1891 there was apparently complete recovery from all the symptoms, save very slight nystagmus. Patient felt quite strong and well.

In 1896 patient became unsteady in walking, and was easily fatigued; knee-jerks were increased, but no ankle-clonus and no tremors existed. Diplopia, blurred vision, and nystagmus were present. Physical disturbances and slight blunting of mental faculties were observed.

(a) Read before the Royal Academy of Medicine in Ireland, November 17th, 1899.

In 1898 intention tremors first appeared; legs became quite rigid; ankle and rectus-clonus and toe phenomenon were present; loss of muscular sense in both upper and lower extremities was very manifest; control of bladder was weak; vision o.d. $\frac{1}{2}$, o.s. $\frac{1}{4}$; hazy discs and nystagmus, but no distinctive syllabic speech.

If only the classical symptoms were to be relied upon in forming a diagnosis the facility for making mistakes become very evident. In this case—1. Nystagmus did not manifest itself for six years after the initial symptoms. 2. A spastic condition of the extremities was fourteen years in making an appearance. 3. Intention tremors appeared after the lapse of sixteen years. 4. Syllabic speech cannot be said to exist at all. The difficulty in arriving at a diagnosis was, therefore, chiefly limited to the earlier years where the transient, ocular, and parietic symptoms might have been considered to be of a functional nature.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, DECEMBER 8TH, 1899.

SIR R. DOUGLAS POWELL, Bt., President, in the Chair.

MR ARTHUR BARKER gave a review of

TWELVE CONSECUTIVE CASES OF PERFORATING GASTRIC ULCER, ON WHICH HE HAD OPERATED DURING THE LAST FEW YEARS.

They were all treated as nearly as possible under the same conditions, and, for this reason, offered an opportunity of contrast with other series in which the procedure was undertaken on different lines. The immediate results were that five out of twelve were saved. Two of the fatal cases lived for fifteen and fourteen days respectively, the first dying of subphrenic abscess and consequent pleuro-pneumonia, the second of bleeding into the stomach from the ulcer, the conditions following the operation being otherwise singularly favourable. The first of these two cases suggested an improvement in technique which favourably affected the subsequent cases. The second case suggested the propriety of excision of the ulcer in certain cases as the only means of preventing subsequent hæmorrhage from it. But in none of the other cases was the ulcer excised, and in none was there any secondary bleeding. In all the twelve cases mopping out of the abdomen was preferred to flushing, the author's previous experience having satisfied him that the latter practice is undesirable in these cases. Drainage was only employed in one case, and was then shown to have been unnecessary. In none of the other cases would it have improved the patient's chances. The bearing of the following factors in similar cases were briefly reviewed "early recognition of perforation," "sex," "symptoms," "previous symptoms," "duration of symptoms of perforation," "liver dulness," "last meal," "conditions found at the operation," "dry mopping versus flushing," and their influence on the series in question. Finally a note as to the remote result in the five successful cases was added. From this it appeared that all were well for a considerable period (amounting to years in some cases) after the operation. Only one case had a threatening of a second perforation which was happily met by rest in bed and careful dieting, the patient being now quite well three years after operation.

MR WARRINGTON HAWARD commented upon the author's statement that many of these cases occurred in apparently healthy people with few, if any, symptoms, a class which he confessed had not come under his (the speaker's) personal observation. He regarded the extreme anæmia as very typical of such cases. He did not think the character of the extravasated material had as much bearing on the future of the case as the time that elapsed before operation. He thought that subphrenic abscess was especially apt to occur when the ulcer had leaked a little, though not to such an extent as to cause

urgent symptoms. A more frequent danger, with ulcer of the front of the stomach, was basal pleurisy. He was pleased that the author preferred sponging to flushing the abdomen, for he himself held that though flushing might be necessary in cases of some standing with extensive contamination, sponging was generally sufficient.

Mr. WALLIS referred to the case of a male seen upwards of twenty-four hours after the onset of the symptoms. There was much peritonitis, but he was quite unable to find any perforation, though there was some induration. He therefore opened the stomach and found two ulcerous patches nearly through, but post mortem they held water very well.

Mr. BOWLEY, alluding to the symptom pain, said that many of these cases were overlooked because everyone expected pain, and he mentioned two cases recently seen by him, in one of them the pain was all in the pubes, and in the other in the lumbar region. In a great many of these cases the pain was limited to the lower part of the abdomen. He pointed out the liver dulness might be present without any perforation, and he instanced a case of intestinal obstruction with considerable distension, in which it was absent. It was the size of the perforation, and the amount of extravasation that determined the acuteness of the symptoms.

Mr. L. A. DUNN said that he had operated upon six cases of perforated gastric ulcer and one duodenal ulcer, the last was a man, and of the others, four were men and two were women. Two men recovered and one woman. In one case he had to operate again a week ago for intestinal obstruction. He referred to a case in which there was loss of liver dulness, but on operating, though the peritoneum was full of gas, there was no fluid, and the most careful examination of the stomach did not reveal any perforation.

Mr. C. S. WALLACE thought flushing the abdomen was a much more satisfactory measure than mopping, but to be efficacious the injection must be large and the intestines should be allowed to float out of the body. He concurred in the view that loss of liver dulness was an unreliable sign.

Mr. F. EVE urged that in these cases they must not wait for particular symptoms. In respect of pain, he alluded to the case of a young woman who had had symptoms of ulcerated stomach and was one morning seized with the typical symptoms of perforation. When he saw her several hours later there was no pain or tenderness in the epigastrium, the only symptom being slight rigidity of the rectum and a rise of temperature. On examining the posterior surface of the stomach, he found a pin-hole perforation. He also referred to two cases of young women with gastric ulcer. One of them was suddenly seized with collapse, pain, retching, and tenderness over the epigastrium, yet the stomach was found perfectly healthy, but pneumonia developed the next day from which she died. With regard to liver dulness, he agreed that it was an absolutely futile sign, and he referred to the case of a young man who had received a blow on the abdomen in whom liver dulness was absent, but on operation nothing was found. He thought most surgeons would prefer flushing to mopping in these cases, and he advocated making a hole between the pubes and umbilicus for the escape of the fluid.

Mr. BIDWELL had collected 55 cases of perforation, in 33 of which the time before operation was mentioned. One third of the recoveries had been operated within six hours, and five others within twelve hours. All the cases which were operated on within twelve hours were successful, and half of those operated on between twelve and twenty-four hours. Mr. Comte had collected notes of sixty-five cases with nineteen recoveries, eleven of these having been operated within the first ten hours. With regard to flushing and mopping that must depend upon the case. In one case he had operated within two hours, and in another within eighteen hours, the pelvis being full of stomach contents. He did not see how it would be possible to remove that simply by sponging.

Mr. BRUCE CLARKE agreed that liver dulness *per se* was a symptom of doubtful value, but in no disease would they rely on any one sign or symptom. He referred to a case where liver dulness was almost absent from extreme distension. The pain might be almost

anywhere, or indeed absent, of which he mentioned an instance. He pointed out that as a general rule the further down the intestinal tract was the perforation the less fatal it was, or at any rate the less acute were the symptoms. Something also must be allowed for the kind of fluid that was extravasated. He agreed with washing out the abdomen, turning out the intestines, and washing out the pelvis, but he admitted that this was not necessary in all cases. He related a case in which he was unable to suture a perforation on the under surface of the stomach, so he simply washed out the cavity and put in a drainage tube with complete success. In some cases he would put in more than one drainage tube.

Mr. BERRY preferred mopping to washing out. He had seen about 12 cases of perforated gastric ulcer, and he had not seen a case recover after washing out, while, on the other hand, the majority of cases treated by mopping recovered.

Mr. BARKER, in reply, speaking in relation to the previously healthy condition of some of these patients, said he had known one of them for some months before the operation and a more wholesome and healthy looking young woman he had never seen. She had told him that she had had no symptoms beyond slight indigestion. It was certainly very important to get these cases early, but it was the character and the amount of the fluid quite as much as the time that determined the result. In three of his cases there was evidence of irritation of the pleura, in one decided subphrenic abscess, and in two, symptoms of sub-phrenic abscess; in one of these there was serum and in the other not, but there was pleurisy. He himself had been greatly addicted to washing out in years gone by, but had been gradually weaned from it. Even when the extravasation had reached the pelvis it could be removed by mopping. In conclusion, he spoke highly of the value of saline infusion made into the areolar tissue.

A CASE OF ARRESTED DEVELOPMENT OF THE SPEECH CENTRE.

Dr. ARTHUR VOELCKER showed a girl, *et.* 7½, who was unable to speak. The child was the elder of two children, her brother being healthy. The father's sister had a child, *et.* 11, who was said to be similarly affected. There was no family history of insanity, epilepsy, alcoholism, syphilis or rheumatism. The previous history of the child was that she was quite well till six months of age, when she had a series of general convulsions ascribed to dentition. These fits recurred occasionally up till the age of three, when they disappeared. She walked at twelve months, but had never spoken. At one year she had a severe fall on her forehead, followed by suppuration but no discharge of bone. At four years she had measles. She had never been violent, passionate or emotional, and had been clean in her habits, though she occasionally soiled her clothes. Though unable to speak, she appeared quite bright and intelligent, and heard well. On admission her present state showed her to be rather small, but well formed. Maximum head circumference 19.75 inches. Forehead scarred in the centre, but no depressed bone felt. Palate high and rather narrow. Motion and sensation were natural, and there was no muscular wasting. The superficial and deep reflexes were natural. Co-ordination good. No tremor of limbs. The child was rather left-handed. She was intelligent, understood what was said to her, and did what she was told readily. Her hearing was normal. Spontaneous speech was limited to a few monosyllabic utterances, chiefly "Eh." Imitative speech included "Eh," "Bee," "Bye," "Baa," "Gee," "Tick," and she repeated sounds with a numerical, though not a phonetic, accuracy, thus her repetitions included the same number of syllables as the word she attempted to repeat. The ticking of a watch did not evoke a rhythmic response. She could sing, but no recognisable tune, nor did she sing scales in unison with the piano. There was no attempt to continue the serial production of sounds as in counting, saying the alphabet, &c. Yes and no were sometimes accompanied by their usual affirmative and negative head gestures. The sight was natural. She could not

recognise printed or written words, numerals, or letters, but readily recognised pictures of objects and objects themselves. She had no recognisable appreciation of colour but distinguished large from small objects. She was unable to write letters, words, or numerals or to copy them. She could, however, copy straight lines and circles with either hand, preferably with the left, but could not make a cross. When writing with the left hand she frequently made her marks from right to left. The case he observed was interesting from the fact that it differed from cases of deaf mutism and from cases of aphasia occurring in mentally deficient children, and from those in whom aphasia developed after the power of speech had been acquired. Dr. Bastian had pointed out in the development of the power of speech, the first stage consisted in learning to associate particular sounds with particular mental impressions, and this stage had evidently been reached by the child, but the second stage in which the power of articulating the sounds which have been used as mental symbols is acquired had not yet been reached by the child. Accepting the existence of a visual and an auditory perceptive centre and a glossokinæsthetic and cheirokinæsthetic centre as maintained by Bastian, it appeared that the two former centres were intact, but that the two latter, or their commissural connections with the first two centres were involved. The observation that the child often wrote from right to left was explicable if it was remembered that movements in the right hand of supination result in a clockwise movement of the thumb, while in the left hand supination results in a counter clockwise movement, and that in movements simultaneously performed in the two upper limbs it was easier to excite corresponding muscles than to make the movements of one side maintain a parallelism with those of the other. Thus it was easier to simultaneously describe two circles with the fingers of the right and left hand respectively—one clockwise and the other counter clockwise—a fact which was also confirmed by the results of an attempt to describe a circle with each hand rapidly, while trying to maintain a parallelism of the two hands. This would tend to show that in mirror writing we have in the left hand represented the movements of the right, and that such movements were the result of kinæsthetic and not visual impressions, and also that it was probable that the centre for writing was, as Elder maintained, in the left hemisphere. The absence of any training in writing made it impossible to determine the extent to which the cheiro-kinæsthetic centre itself was involved, and the same held good with regard to speech and the glosso-kinæsthetic centre. The disease must affect the region of the posterior parts of the second and third left frontal convolutions, and was probably not a gross lesion but due to arrested or inhibited development of function of the glosso- and cheiro-kinæsthetic centres or their connections with the auditory and visual perceptive centres. The prognosis was favourable and the treatment recommended was instruction in writing and in the lip language.

In reply to the President, Dr. VOELCKER said he thought they must look to the convulsions as having in some way damaged the region referred to, producing arrested development, though the lesion might not be amenable to investigation.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

MEETING HELD FRIDAY, NOVEMBER 17TH, 1899.

The President, Dr. JOHN W. MOORE, in the Chair.

Dr. CRAIG showed a man suffering from
CEREBRO-SPINAL SCLEROSIS.

The case is published under the head of Clinical Records.

In the discussion that followed the PRESIDENT

observed that as this disease was so liable to be confounded with hysteria that it was worthy of the attention of all clinical and practical physicians.

Dr. J. B. COLEMAN said that the disease was not very uncommon. A case which he had under observation at present did not differ very much from the case exhibited.

Dr. FINNY took exception to one of the diagnostic points Dr. Craig had mentioned as distinguishing this disease from hysteria. The statement he referred to was that ankle-clonus was not present in hysteria. He had a clear recollection of ankle-clonus occurring distinctly in a case of pure hysteria, and ankle-clonus, which was once thought of great value as pointing to structural changes in the pyramidal tract and cord, was not now considered so trustworthy. In many cases of typhoid fever ankle-clonus could be found where there was no evidence of hysteria or structural disease of the spinal cord.

Sir GEORGE DUFFEY said he could corroborate what Dr. Finny had said about the presence of ankle-clonus in hysteria. He remembered a case in the City of Dublin Hospital which presented peculiar nervous symptoms, and about which there was great doubt as to the diagnosis.

Dr. KNOTT said that Sharpe's great test was to ask the patient to shake hands. In cases of chorea the patient made a series of jerky movements, whereas in disseminated sclerosis the patient always went in a curved line. He was struck with the extraordinary similarity in the way patients suffering from this disease carried their heads. He noticed that the pupils of the patient exhibited were a good deal larger than normal. He suggested that the peculiar monotone of the speech could have been better demonstrated by getting the patient to recite prose rather than poetry.

Dr. B. TRAVERS SMITH mentioned a case of a girl, *et. about 22*, who presented the clinical group of symptoms known as spastic paraplegia. The diagnosis between insular sclerosis and primary lateral sclerosis was at first doubtful, but the question was finally settled at the end of a few months by the patient developing an external strabismus, which he considered was an important sign in the diagnosis of insular sclerosis. After that other symptoms of the disease had set in.

The PRESIDENT (Dr. J. W. Moore), referring to Dr. Finny's remark, suggested that at a certain period in typhoid fever there might be structural changes in the spinal cord. Such changes are, however, of a transitory nature, and just as the heart suffers in zymotic diseases so also the spinal cord may suffer from a purely temporary organic change.

Dr. CRAIG, in reply, said that, with reference to Dr. Finny's remarks, he agreed that in severe illness, and, indeed, in many chronic diseases, structural changes might take place in the cord and ankle-clonus and other symptoms be evinced. In answer to Sir George Duffey, the third case he (Dr. Craig) had referred to often got perfectly well for two years, and it was sixteen years before they knew she was not suffering from hysteria.

SENILE DEMENTIA.

Dr. CONOLLY NORMAN read a paper on senile dementia. He dwelt on certain points of clinical interest, emphasising the fact, which he held is too often forgotten, that this form of mental trouble may appear with apparent rapidity, and often seems to develop after an attack of acute physical illness—influenza or the like. Dr. Norman pointed out that the most typical mental condition in senile dementia was characterised, not only by a forgetfulness of recent events, but also by an abnormal acuteness of recollection of events long past. He, therefore, thought that mere amnesia did not cover the field. He gave a somewhat detailed description of the conditions of aphasia, paraphasia, and alexia, which we sometimes met with in cases of senile dementia.

Dr. NINIAN FALKNER inquired if there was generally albuminuria in cases of senile dementia, and asked if it was a fact that there was a train of mental symptoms in chronic Bright's disease closely resembling those of senile dementia?

Dr. LAW said he had a little experience of asylum work in England and afterwards in British Guiana, and a point that struck him when in the latter place was the

large number of cases of senile dementia in comparatively young subjects, where in this country they would expect an attack of more active mental disease. He also noticed that cases of that kind were commonest in the lowest race: in the colony.

Dr. NORMAN, in reply, said that albuminuria and bad kidney disease associated with senile dementia was only what they might expect. He could not, however, subscribe to the theory of some nervous pathologists that senile dementia depended upon arterio-sclerotic conditions in the brain, although it was undoubtedly true that gouty kidney and extensive arterio-sclerosis was common in persons dying of senile dementia. Consequently the two conditions—mental disturbance and albuminuria—co-existing would not surprise him. With regard to the racial question, Dr. Law's remarks bore out his statement that the more the brain was used the less the probability of the occurrence of senile dementia. The Section then adjourned.

OBSTETRICAL SOCIETY OF LONDON.

MEETING HELD WEDNESDAY, DECEMBER 6TH, 1899.

MR. ALBAN DORAN, F.R.C.S., President, in the Chair.

DOUBLE HYDRO-SALPINX WITHOUT SALPINGITIS.

THE PRESIDENT showed an interesting specimen of obstruction and dilatation of both Fallopian tubes without evidence of salpingitis, though there were perimetritic adhesions in abundance. He recalled the fact that ten years ago in a paper on "Closure of the Ostium in Inflammation of the Fallopian Tube," he applied the term "perimetritic closure of the ostium" to this form of occlusion which had since been observed and described by Dr. Cullingworth and others. The specimen was removed from a young married woman who came complaining of severe pelvic pains in the left iliac fossa, of six months' standing. The periods were irregular and clots passed freely. She had two abortions the last four months previously. Temperature was normal. On opening the abdomen he at once came upon the two dilated tubes which he removed, after breaking down the adhesions, purposely leaving a little ovarian tissue on the left side. An uneventful recovery followed. The tubes were much dilated and sharply bent upon themselves. The mucous membrane was lined with perfect epithelium which had lost its cilia. The specimen is now in the Museum of the Royal College of Surgeons. With this specimen he showed two others of obstructed tube with perimetritic and salpingitic obstruction in their earlier stages, and a third showing how the fimbriae retract mechanically. He hoped that the catamenia might continue in this case, but one could not be sure of this. He justified his removal of the tubes on the ground that the usual course of such a case was ultimate suppuration with close adhesions of the tube to the rectum, small intestine and appendix. He did not perform salpingostomy because he suspected a specific origin.

Dr. A. ROUTH said he had opened and drained the tubes *per vaginam* with good results. One patient had double pyosalpinx yet subsequently became pregnant and aborted.

Dr. HORROCKS said he had recently operated on a young married lady in whom, on opening the abdomen, both tubes were found filled with tubercle. He laid them freely open and a sinus formed which had continued to discharge until three weeks ago. They could not be removed on account of extensive tuberculous mischief in the pelvis.

The PRESIDENT remarked that no one seemed to have performed normal salpingostomy. He doubted whether it was a legitimate operation seeing that it was liable to set up pyosalpinx.

COLPOTOMY FOR REMOVAL OF OVARIAN CYST.

Mr. ROBINSON related a case in which he had effected the removal of an ovarian cyst containing 8½ pints of fluid through an incision in the roof of the vagina after

tapping through the incision. The result had been excellent.

TUBAL PREGNANCY (MOLAR) COMPLICATED BY SUPPURATING OVARIAN CYST.

Dr. JOHN PHILLIPS showed a specimen removed from a woman, *set.* 40, the mother of ten children, who came on August 5th, 1898, complaining of pain in the left iliac fossa. The last period was in May. A lump was felt in the left and posterior quarter of the pelvis. She had a sudden attack of pain on August 25th with vaginal hæmorrhage which persisted. He was called to her on September 26th. The legs moved with difficulty, but were comfortable in the extended position. Temperature, 100; pulse, 108. Through the hypogastrium he felt a bilobed swelling occupying the whole of the lower abdomen. There was a free hæmorrhagic discharge, and the uterus was pushed against the symphysis pubis by a smooth impacted swelling, occupying the posterior and left two-thirds of the pelvis. Higher up and to the right the base of a smaller swelling could be felt. The sound passed 3½ inches into the uterus. He saw her again on October 17th, when she seemed to have lost ground. He opened the abdomen and came upon a semi-elastic tumour, generally adherent. Deep down on the pelvis floor the finger passed through an orifice in the sac-wall, blood clot and putrid fluid escaping. The tumour proved to be an extra-uterine sac and a fetus three inches long projected through the wall. The pedicle was ligatured and the mass removed. The tumour on the right side contained flocculent pus, and it proved to be a right ovarian cyst undergoing suppuration. This was also removed. The abdomen was washed out, and a glass drainage tube left in. The patient made a perfect recovery after three days' anxiety from collapse. She subsequently had severe epistaxis at the menstrual periods. In the specimen the tube was enormously distended, measuring 12 ins. in its longitudinal circumference, 10½ ins. in the transverse, and 9½ ins. in the vertical circumference. The uterine orifice was still patent, but the abdominal end was occluded. The tube had ruptured through the peritoneum. He referred particularly to the constant hæmorrhage, a sign which, according to Dr. Cullingworth, was present in nearly all these cases.

Dr. HERMAN pointed out that in many cases tubal moles had been removed which were not causing any trouble, and he raised the question whether they could be left with safety. He admitted, however, that the author's case militated against this view.

Dr. HORROCKS said that many of these cases got well without septic complications, and probably many cases of ectopic gestation were thus recovered from without attracting attention.

Dr. GALABIN said he had seen a number of cases which had not been operated upon in which the lump had gradually diminished in size, and in other cases in which he had operated he had only found clot with little chorionic villi. The question of operation would depend upon the size of the ovum, and when under two months he thought the case might be left to nature.

CASE OF ACUTE IDIOPATHIC (?) PERITONITIS COMPLICATING PREGNANCY AND LABOUR.

Dr. JOHN PHILLIPS related the case of a woman nearly seven months pregnant and in good health, who fell over a chair-back on her left side. Much pain and persistent vomiting followed. She was found in a very serious condition, her abdomen distended, pulse 120, temperature 103 degs. F., and respirations 48. Labour came on, but no true pains could be distinguished, and terminated very quickly. Her condition became rapidly worse, and she was admitted into King's College Hospital. After consultation, Mr. Peyton Beale opened the abdomen, and found general peritonitis, but no apparent cause. The patient died in a few hours. Full details of the post-mortem examination were given. Short histories of five other cases were related—Matthews Duncan (two), Simpson, Romiti, and Gow. The author pointed to three important points for discussion, viz., (1) the cause of the infection; (2) the question of operative interference; (3) the share the blow took in producing the illness.

Mr. ROBINSON admitted that he was very puzzled to explain the patient's symptoms when first seen.

Dr. INGLIS PARSONS urged that there was always the possibility of infection by the bacillus coli. He supposed the author did not really regard the peritonitis as "idiopathic."

The PRESIDENT asked if any one knew of a case of primary infection of the peritoneum as a result of the escape of fluid from the tube?

Dr. A. ROUTH referred to a paper by Mr. Treves, read many years ago before the Medical Society, in which he described peritonitis due apparently to infection by the bacterium coli, after bruising, &c, of the intestine, a possibility which has been proved by clinical and experimental observation.

Dr. HORROCKS said the term "idiopathic peritonitis" had long been abandoned in its original sense.

Dr. GALABIN referred to a mysterious case of peritonitis in a girl, æt. 17, whose abdominal cavity was distended with semi-purulent fluid, the pelvis being free, and there being no evidence of salpingitis. The patient unfortunately died under chloroform, and there was nothing to show where the inflammation had started.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD AT THE MEDICAL SCHOOL, LEOPOLD STREET, SHEFFIELD, NOVEMBER 17TH, 1899.

The President, Dr. DONALD, in the Chair.

Dr. J. W. MARTIN showed a pedunculated subperitoneal fibroid removed by abdominal section.

Dr. W. WALTER also showed microscopic specimens.

Dr. W. J. SINCLAIR related a case of abdominal pregnancy, and showed the specimen along with drawings. The fœtus, which was well developed, together with the placenta, was removed by abdominal section. The fœtus lay free in the abdominal cavity. There was no evidence of an amniotic covering. The patient made a good recovery.

Remarks were made by Dr. Keeling and the President. Dr. Sinclair replied.

Dr. T. ARTHUR HELME related two cases of extirpation of the uterus for extreme hypertrophy and prolapse. The patients, multiparae, æt. 47 and 52 years, had suffered for many years from prolapse of the uterus, along with the anterior vaginal wall and bladder. The posterior vaginal wall was not everted. The cervix was extremely hypertrophied. The fundus uteri was felt in its normal position behind the pubes in each instance. The length of the uterine cavity measured 5½ ins. and 6½ ins. respectively. The operation performed was as follows: The uterus was removed in the usual way, by ligaturing the broad ligaments in section. The peritoneal cavity was completely closed by careful suturing. By means of buried sutures the large, raw connective tissue area covering the bladder was diminished, and the bladder folded upon itself. The cut edges of the vaginal walls were then sutured, a broad surface being united. At a second operation, the perineum was repaired and the vaginal outlet narrowed. The results were quite satisfactory, the patients walk well, have no bladder trouble, and do not require a pessary. Extirpation of the uterus alone will not cure complete prolapse of the vaginal walls which forms a hernia of the pelvic floor. In these cases plastic operations combined with ventrofixation of the uterus give good results.

Dr. LEA remarked that in these cases it is always advisable to remove the ovaries and tubes, inasmuch as they often became prolapsed and painful. This might necessitate their subsequent removal.

Remarks were made by Dr. Sinclair and the President, and Dr. Helme replied.

Dr. W. K. WELLS related a case of double ovarian abscess with purulent salpingitis in which the uterus and appendages were removed by the vaginal radical operation. The patient, a multipara, had pyrexia and pelvic inflammation. Whilst under observation rapid enlargement of each ovary was detected. Ovarian

abscess was diagnosed, and the operation at once performed. Each ovary was a thick walled sac of pus. Both Fallopian tubes were swollen and infiltrated. They contained purulent secretion, but the fimbriated extremity was not occluded. The patient made an excellent recovery.

The PRESIDENT (Dr. Donald) related two cases of unusual abdominal tumour. Case I. A tumour of the suprarenal capsule. The patient, æt. 37, married, had an abdominal swelling which was the size of a foetal head at term. It was very mobile and fluctuant, and could not be pushed down into the pelvis. A diagnosis of cyst of the kidney or ovarian cyst with a long pedicle was made. On opening the abdomen the tumour was found to be retro-peritoneal, and crossed by the descending colon. The peritoneum was divided and the cyst enucleated. There was no pedicle. The cyst lay immediately in front of the left kidney, which was normal. The patient made a rapid recovery. On section the tumour contained blood and clots. The cyst wall showed fibrous septa enclosing polyhedral granular nucleated cells closely resembling the "zona glomerulosa" of the normal suprarenal capsule. Case II. Cystic sarcoma of the pelvis.—Patient, æt. 26, single, had a symmetrical cystic tumour springing from the pelvis and reaching the level of the umbilicus. The uterus was small and separate from the tumour. An ovarian cyst was diagnosed. On opening the abdomen the cyst was found to be retro-peritoneal. The peritoneum was incised, and the cyst punctured. Three pints of blood-stained fluid were evacuated. The cyst was not connected with the uterus or appendages, but was found to grow from the connective tissue near the left sacro-iliac joint. The tumour was shelled out with difficulty, and the patient made a good recovery. Microscopically it was a round-celled sarcoma with cystic degeneration. These cases were striking examples of the difficulty of accurate diagnosis of abdominal tumours.

GENERAL MEDICAL COUNCIL

OF

EDUCATION AND REGISTRATION. WINTER SESSION, 1899.

Sir WILLIAM TURNER, President, in the Chair.

SIXTH DAY.—MONDAY, DECEMBER 4TH, 1899.

The PRESIDENT announced that the Committee on Mr. Upton's letter would consist of Mr. Bryant, Dr. Pye-Smith, Dr. MacAlister, and himself.

RECIPROCITY OF MEDICAL PRACTICE.

Speaking to Sir Dyce Duckworth's motion Mr. TOMES moved as an amendment "that the Privy Council be requested to obtain information (a) whether any change in the regulations affecting foreign practitioners in Italy had been made since the communication received in 1898; (b) whether any such change was in contemplation by the Italian Government. He justified his amendment on the ground that the Council ought not to proceed on private information when official information was procurable. The Council ought not to act without some sort of pledge on the part of the Italian Government that they were not going to depart from the present order of things. He did not think the Italian Government would act precipitately while official communications were passing on the subject.

Sir C. NIXON seconded the amendment in order to gain time, and in the hope that the matter would not come before them again. He deprecated altering existing requirements for the convenience of foreigners.

In reply to Sir Dyce Duckworth, Mr. TOMES declined to allow his amendment to be added as a rider to the motion.

Sir DYCE DUCKWORTH read a letter, dated December 2nd, from a trustworthy source, to the effect that our Government had in some way led the Italian Government to understand that they declined reciprocity,

thereby cutting the ground from under the feet of those who were seeking to secure for British medical men the privileges at present enjoyed by them in Italy. He pointed out that Italy was now the only country to which that section of the Act could apply. Under the circumstances he was willing to withdraw his motion in favour of the amendment.

The amendment thus became the motion before the Council.

Dr. McVAIL regretted that the Act did not allow them to limit the practice of foreigners to their own countrymen, and he proposed that the Privy Council should be asked to have the Act amended in this direction.

The motion was then agreed to.

EDUCATION COMMITTEE.

The PRESIDENT laid before the Council the *précis* drawn up for transmission to the German Government in reference to the admission of foreigners to examinations for British registrable qualifications, and on the motion of Dr. MACALISTER it was received and entered on the Minutes, the same to be transmitted to the Privy Council as an answer to the questions contained in the dispatch of the German Ambassador.

Mr. VICTOR HORSLEY moved that the report be sent back to the Education Committee for reconsideration of the circumstances under which certain qualifying bodies admitted foreigners to their final examinations. On the suggestion of the PRESIDENT he promised to give notice of the motion.

FINANCES OF THE IRISH BRANCH COUNCIL.

Sir C. NIXON asked whether the Council would have an opportunity of discussing the opinion of Mr. Muir Mackenzie with regard to the financial position of the Irish Branch Council.

Dr. MACALISTER observed that the document was strictly confidential, but it would be in order to move that the Council should go into *camera* for that purpose.

THE ENGLISH COLLEGES AND THE COUNCIL.

On the motion of Mr. BRYANT, two communications from the Royal Colleges of Physicians and Surgeons of London were received and entered upon the Minutes, declining to recognise the Council's requirement that scientific institutions where medical study is commenced should be approved by the General Medical Council.

Sir WILLIAM THOMSON regretted very much that this matter had come up again. He reviewed the history of the matter, and maintained that if the Colleges were allowed to challenge the authority of the Council on this particular matter, itself possibly of small moment, the Council would have no authority in any matter over them, and if this position were acquiesced in they would not have long to wait before all the other Colleges and Corporations and Universities would defy the Council. Referring to Section XX. of the Act of 1858, he insisted on the right of the Council to intervene, and in support of this view he quoted certain clauses from the report of the Education Committee of May, 1894. He insisted that the two colleges had not only departed from the original arrangement as to the five years' course, but that they had also failed in their duty in their own arrangements for inspecting these first-year scholars. He mentioned that in the discussion at the College of Physicians in London last year two of the members of Council, Fellows of the College, took the same view. He maintained that it was the duty of the Council, at whatever cost, if it wished to retain the regulation of medical education, to assert its authority. He concluded by moving that the Registrar be directed to inform the Colleges that the Council adhered to its resolution.

This was seconded by Dr. BRUCE.

Dr. MACALISTER thought the effect of the resolution would be very small, remarking that the only result would be a hardship on the students who had been misguided enough to seek registration without having fulfilled the proper conditions. These would have to go back to the Colleges or enter some recognised science class, and the Colleges would make nothing of their refusal to comply with the Council's regulations.

Dr. McVAIL asked whether they were to understand that the resolution as to the registration of medical students was a farce. He complained that the Colleges did not enter into the merits of the question, but simply defied the deliberate opinion of the Council.

Sir PHILIP SMYLY said he had already brought the matter before Council, but it had been shelved.

Sir RICHARD THORNE thought the action of the Colleges deplorable.

Dr. ATTHILL observed that if the Colleges would not reconsider the question the Council would have to put the subjects of chemistry and physics after biology, in the preliminary examination, return to the four years' course, or appeal to the Privy Council.

Sir J. BATTY TUKE thought their contention would be maintained by the Privy Council.

Mr. BRYANT repudiated any desire on the part of his College to place itself in opposition to the Council, but it was felt that the Colleges had their own responsibilities and duties. He maintained that they had done much good by encouraging the teaching of scientific subjects in the big schools. He asked how the Council could select schools and places of scientific instruction.

Dr. PAYNE did not think the question was arguable, and moved as an amendment that the right of the Council in respect of the matter at issue should be referred to their legal adviser.

Dr. MACALISTER said an opinion had already been obtained to the effect that the Council had an inferential right to enforce conditions of registration, though there was no specific clause in the Act referring to it.

Sir DYCE DUCKWORTH observed that the Council must keep within the four corners of the Act, and they would only be justified in appealing to the Privy Council if of opinion that the curricula were not such as to secure adequate teaching, and this, he asserted, had not been shown to be the case.

Mr. CARTER did not think the Council was to be altogether confined within the four corners of its statutory powers, but ought to be regarded as a means of enabling them to meet and discuss matters and principles of education. He hoped the Royal Colleges would come into line and endeavour to carry out the wishes of the great majority of the members of Council.

Dr. PETTIGREW urged that if the views of the Royal Colleges were adopted, they would be the means of introducing a disastrous element, and he hoped the Colleges would reconsider the matter.

Dr. LEECH thought the question depended on whether they thought the teaching school was satisfactory or not.

Sir C. NIXON denied that it was a question of sufficiency or insufficiency, the real test being whether the authority of the Council was going to be recognised by the Colleges or not.

Dr. HERON WATSON observed that no objection had been made to the Council's regulations extending the period of medical education until now.

At the suggestion of Dr. MACALISTER, Sir WILLIAM THOMSON agreed to make his motion read as follows:—"To invite the Colleges to take the matter into fresh consideration in view of its important bearing on the maintenance of the standard of study and examination in the country at large." Sir William disclaimed any personal feeling in the matter, observing, however, that if the Colleges declined to obey they would have to go to the Privy Council.

On the motion being put to the vote, 22 voted for, 1 against, 3 did not vote, and 4 were absent.

FINANCES OF THE BRANCH COUNCILS.

After considering in *camera* Council's opinion on the financial position of the Irish Branch Council, the PRESIDENT announced that a resolution had been agreed to that the whole question of the funds of the Council and its Branches should be referred to the Finance Committee and respective trustees to take legal advice and report next session.

REPORT OF PERSONATION COMMITTEE.

The report of the Personation Committee was received and entered upon the Minutes, but on the motion of Dr. McVAIL the discussion was adjourned until next session.

PRELIMINARY EXAMINATIONS.

Sir J. BATTY TUKE brought forward the report of the Education Committee on the question of raising the minimum requirements of the Council in regard to preliminary examinations. The report recapitulates the steps that have been taken in regard to the appointment of experts. In regard to the substitution of the senior and higher grade, for the junior, examinations, the experts were unanimously of opinion that, taking into account the present state of secondary education in the country, no such requirement could possibly be enforced. They point out that a demand of this kind would certainly result in defeating the end which the General Medical Council have in view. Either it would diminish to an indefinitely large extent the number of candidates entering the profession, or it would compel the examiners to a laxity of marking and a depreciation of the standard of questioning which would merely have the effect of lowering the senior papers to the level of the junior papers. The standard of the Medical Preliminary Examination must depend upon the general standard of the secondary education of each country in which the examination is held, and a standard too high for one might be found too low for another. They think, however, that the immediate object of the General Medical Council would be gained by the gradual raising of the standard of the lower "Junior" examinations to the level of those "Junior" examinations which, in their opinion, rank highest.

In view of this opinion, the Committee maintained their view that a number of the junior examinations must, for a considerable time yet, continue to be recognised. They propose, however, to give effect to the specific recommendations of the experts in regard to enlarging the scope and raising the standard of these examinations, with which object in view, the Committee ask authority to retain the services of the experts, and to have allocated a further sum of £100.

Sir J. BATTY TUKE pointed out that the opinion of the experts coincided with that expressed by the Education Committee in June last, and must be accepted as final for the present.

Dr. MACALISTER thought these opinions deserved the Council's gravest consideration.

Sir RICHARD THORNE said they were asked to adopt the report without seeing on what it was based, and he moved as an amendment that the reports should be circulated among members of Council. He thought it was the most "staggering" conclusion he had ever heard, and he thought the Council should not take a tremendous leap in the dark.

Dr. RYD seconded the amendment.

Dr. LEECH said there were many questions on which information was required before the report could be passed.

Dr. PYE-SMITH said he knew from experience that the standard was lamentably and disgracefully low, and he hoped the Council would be able to refuse to accept the report.

Mr. HORSLEY said that he and his fellow representatives had an absolute mandate to raise the standard of preliminary examinations by all means in their power. As for the report, it simply baffled him. He concluded by observing that the opinion of these experts was not only a disappointment, but a very expensive disappointment.

The further discussion was adjourned.

SEVENTH DAY.—TUESDAY, DECEMBER 5TH, 1899.

ADJOURNED DEBATE ON PRELIMINARY EXAMINATIONS.

Sir RICHARD THORNE, in resuming the discussion, repudiated the least desire to convey anything that might hurt the feelings of the Education Committee, whose labours he admitted had been great. Nevertheless he felt that they ought to have before them the reasons on which was based the report which practically put an end to their aspirations and which, if fulfilled, would have done more than anything else to raise the status of the profession from its, in many respects, deplorable condition. He had read the report with the keenest disappointment and he did not think the Council could deal with the subject on the materials at present before them. He

therefore proposed, as an amendment, "that the Education Committee obtain from the experts a report setting out in full their reasons for the conclusions they had arrived at with regard to the adoption by the Council of the senior and higher grade standard of preliminary examinations, and that the sum of £100 be placed at the disposal of the Committee for that purpose."

Sir J. BATTY TUKE accepted the amendment on behalf of the Committee.

Dr. MACALISTER recalled what took place last year when a clear line of work was indicated for the future.

Dr. McVAIL suggested that if the Council laid down and rigidly enforced the minimum examination requirements, the schools of the country would respond loyally. There might be a temporary decline in the number of students, but after that they would get a superior class of men.

Sir Richard Thorne's amendment was, by consent, substituted for the original motion.

Dr. GLOVER pointed out that the £100 was intended not only to enable the Committee to justify the report, but for further services. He shared in the disappointment at the report.

Sir C. NIXON remarked that it was obvious that it would be impracticable to adopt the senior examination as their standard, this examination corresponding to the first examination in arts at the Royal University. He thought the Council would act wisely in leaving the matter in the hands of the Committee and the experts.

The motion was then agreed to, the concluding words "for that purpose" being deleted.

THE APOTHECARIES' HALL OF DUBLIN.

Sir DYCE DUCKWORTH read the report of the Examination committee on the examinations of the Apothecaries' Hall, Dublin, held in July, 1899. The examiners direct the attention of the Council to the lack of general education evinced by one of the candidates, but the preliminary examination passed by this candidate is not mentioned. The Inspector reports that the final examination will bear favourable comparison as a test of fitness with any of the ordinary pass examinations of the United Kingdom. The Surgical examiners were satisfied with the way in which the examination was conducted and with the standard of knowledge required. The Committee recommend the Council to ascertain the particular arts examination which the imperfectly educated candidate had passed. They suggest that a copy of the report should be sent to the Privy Council, and that the inspections should be continued.

Mr. TICHBORENE objected to individual allusions in the report and criticised the wording thereof in other respects. He concluded by proposing as an amendment that the words complained of should be left out.

Mr. G. BROWN seconded the amendment with the hope that the Committee would acquiesce in the suggestion.

The suggestion was acceded to, and the motion was then agreed to.

PHARMACOPEIA COMMITTEE.

The Report of the Pharmacopœia Committee was received and adopted, and the Council then received *in camera* a report from the Penal Cases Committee. The Report of the Public Health Committee was received and entered on the Minutes, and the Report of the Students' Registration Committee in Exceptional Cases was also received and entered on the Minutes.

UNQUALIFIED DISPENSERS.

A report from the Unqualified Dispensers' Committee was received and entered on the Minutes. The conclusions arrived at by the Committee are that they do not see their way at present to recommend any course to be taken by the Council, but they endorse the reply sent by the Executive Committee to the Privy Council.

COMPANIES' ACT AMENDMENT COMMITTEE.

The report was received and entered on the Minutes. The Committee urge that the words "Medical Practitioner" ought to be added to the clause, adding that both medical and dental companies were still actively pursuing highly objectionable forms of practice.

MEDICAL AID ASSOCIATIONS.

The Committee report favourably on the constitution of the proposed Conciliation Board, and it was hoped that a better understanding would be arrived at with the Societies.

LOSS OF RIGHT TO PRACTICE.

Sir C. NIXON brought forward a motion to the effect that when a practitioner's name had been removed from the *Register* he should be officially informed that he had forfeited the legal right to practise, but, at the suggestion of the President, he consented to withdraw it.

ADMISSION OF FOREIGNERS TO BRITISH EXAMINATIONS.

Mr. VICTOR HORSLEY moved that the Education Committee be asked to consider the circumstances under which foreigners obtained exemption from some of the conditions of education and study. He urged that foreigners should be required to produce evidence either that they were qualified to practise in their own country or that they had followed out the five years' curriculum of this country. He mentioned that at some of the Scottish Universities—Aberdeen, for example—a student was allowed to pass three years of his curriculum elsewhere.

The motion was carried by 10 votes to 8.

THE RHODESIAN MEDICAL ORDINANCE.

On the motion of Mr. CARTER it was resolved to forward to the Secretary of State a copy of a resolution to the effect that the memorial drawn up by medical practitioners in Southern Rhodesia against the validity of the Ordinance under which they acted was justified, and indicated a serious grievance of which they were warranted in complaining.

The first year's examination of the University of Adelaide was ordered to be recognised as qualifying for registration for medical and dental registration and, after a vote of thanks to the President, the Session came to an end.

PARIS, December 9th, 1899.

ARSENIC IN ANIMALS.

At the Académie de Médecine M. Gautier said that he made researches which permitted him to affirm the constant presence of arsenic in the thyroid glands of all herbivorous and carnivorous animals, and in man himself, but in very small quantities. In all the other organs except in the thymus, the brain and the skin where it existed in smaller quantities than in the thyroid gland, no arsenic was found. The same might be said of the blood. In the thyroid gland of man he found one milligram (fiftieth of a grain) of arsenic for 127 grammes of gland. This arsenic was furnished by a certain number of aliments, and was carried, probably by the white corpuscles to the nucleus of the cells. A point which the speaker considered worthy of attention on account of the consequences which might result from a therapeutic and pathological point of view was that the presence of arsenic was as necessary as that of iodine to the proper function of the thyroid gland.

M. Brouardel remarked that from what had been said, they should not come to the conclusion that the presence in the normal state, of arsenic in any appreciable quantity in certain organs, affected medico-legal examinations, in which that metalloïd had been met with, the quantities of arsenic, on which were based the conclusions of the examinations being always much greater than those indicated by the first speaker as

existing in the normal state. M. Gautier replied that the facts he had related established on the contrary that arsenic was only found in the normal state in the thyroid the brain and the skin. Arsenical poisoning consequently might be inferred where the metalloïd was found in the liver, spleen, muscles, blood, &c.

COXALGIA.

M. Kirmission referring to the communication of M. Nelaton at the previous meeting, anent the treatment of hip-joint disease by resection, said that although he might be a partisan to active interference in the adult he was decidedly conservative in the coxo-tuberculosis of children, so long as the skin remained healthy conservative methods might be pushed very far. Injections of a solution of iodoform and ether (1-10) frequently brought about a cure in suppurating coxalgia. Even in cases complicated with fistula excellent results might be hoped for from this treatment.

As regarded the curative value of resection for coxalgia, it should be admitted that many of those operated on had fistula tracts resulting from the fact that it was not always possible to remove the fungosities completely. He had the opportunity of examining ten patients who had been operated on; three presented fistulae and four had the limb in a bad attitude, while the shortening varied from 1½ ins. to 4 ins.

INCOMPLETE CONSOLIDATION OF FRACTURES.

M. Potheral related two cases of incomplete consolidation of fractures treated successfully with the administration of thyroid gland. The first case was a comminuted fracture of the leg treated by the stiff bandage and massage. At the end of eighty days, no consolidation having taken place the thyroid gland was prescribed, and after fifteen days the desired result was obtained. The second case was somewhat similar, but on the eleventh day of the administration of the gland, the patient was seized with cerebral hæmorrhage, and presented symptoms of danger.

The results obtained, said M. Potheral, by thyroid medication in the treatment of retarded consolidation appeared to have given satisfaction in a certain number of cases. However, it should not be forgotten that the medication was attended with more or less danger.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, December 9th 1899.

At the last meeting of the Society for Innere Medizin Hr. J. Boaz read a paper on

EXPERIENCES IN CANCER OF THE COLON.

He had a material of fifteen cases (twelve in men, and three in women). In eight cases the tumour was demonstrable, in six its seat was the cæcum, and two, the hepatic flexure of the colon. Twelve cases were treated by operation. He divided the cases, according to the subjective symptoms, into four groups. (1) Only slight gastric disturbances, and here the diagnosis was difficult. (2) More precise symptoms that fixed the attention on the disturbed intestinal function, the symptoms not being very characteristic. (3) The history and subjective symptoms directed the attention, from the first, to the bowel, and were indicative of the nature of the trouble. The history here was of a stereotyped character. The patients had had no

previous trouble in the bowels, or only slight. Suddenly severe symptoms supervened, with paroxysmal pain, nausea, and vomiting. The attacks then became frequent and more severe, from a stenosing carcinoma; if the disease was seated in the sigmoid flexure, there was tenesmus in addition to the other symptoms. (4) In the midst of seeming good health ileus came on, without distinct indications as to the nature of the disease. On careful inquiry earlier indication will be brought to light. Sometimes errors in diet have been blamed as the cause, sometimes not.

The existence of a tumour was more important as regarded diagnosis. Of the eight cases in which the tumour could be felt, in only two could it be distinctly moved, and these tumours were in the cæcum with a short mesentery. The temporary disappearance, sometimes for two or three days, was of importance. By this was shown the importance of repeated examination, both with the bowel full and empty, in order to protect against errors of diagnosis. In order to test the movability of a tumour, artificial blowing up of the bowel was of importance, and also palpation in the warm full bath.

It was important to distinguish between innocent and malignant tumours, and especially between tumours on cecal and perityphilitic exudates. The speaker had had two cases in which it was very difficult to distinguish such tumours from tuberculous ileo-cæcal tumour. The diagnosis was facilitated by indications of tuberculosis in the faces, and by the musical intestinal sounds said by König to be heard when the stenosed part is of length. One especially good means of distinction lay in the diazoreaction observed in tubercle. It had been confirmed in recent times that this was always absent in the case of malignant tumours. A valuable sign was furnished by the symptoms of stenosis. Subjectively, there was severe colic with nausea and vomiting, and objectively, independent of meteorism, tetanic peristaltic movement. The symptoms often receded for a time with careful dieting. Repeated tension of a small coil of intestine with subsequent relaxation was an important sign. All cases exhibiting such symptoms should be taken to the hospital for further observation. He had seen hamatemesis in two cases, in which the blood regurgitated from the lower segments of intestine. As regarded the feces, the presence of blood and pus was important. Serious bleeding was only seen in two of the fifteen cases. He had never seen particles of the tumour in the stools except after washing out. The general condition sometimes oscillated more than might have been expected; he had seen an increase of weight of three kgms. in a week. As regards diet, some kinds of food should be avoided—skin fruit, Graham bread, and asparagus—they might originate an attack of ileus. In attacks of stenosis purgatives were generally useful, but in some cases opium was the best.

Of his twelve operation cases five were resection, with two deaths. One being still alive and well after four years, four well after being operated on five months. In four cases enteroanastomosis was performed. (One death from perforation, one patient living after nine months, two after six months.) In one case an anus præternaturalis was made—death after four months.

The results of operation were not very encouraging. Most of the cases were operated on too late. With

early diagnosis and operation, the result would have been better.

Operation was indicated in movable tumour and good general condition. The form of operation could not be decided before the abdomen was open. As metastases generally took place late, extirpation afforded tolerably favourable chances. Further, operation should be performed even when no distinct tumour could be felt, if symptoms of stenosis were marked, and also in the case of ileus.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, December 9th, 1899.

SYRINGO-CYST-ADENOMA.

At the "Gesellschaft der Aerzte," Neumann showed two cases of syringo-cyst-adenoma originating in the sweat glands. It was present on the anterior and lateral surfaces of the thorax over the mammae, down the back, on the flexor aspects of the extremities, on the face and eyelids, in the form of small tubercles ranging in size from small shot to peas, granular on the surface, and varying in colour from a bright red to a dark brown or purple colour.

In both cases the history and appearances were the same. This condition had existed more or less since early childhood, but had increased in extent of late, decidedly so since they had entered hospital; some of the tubercles becoming flat and cystic during this period.

In many respects this affection resembles xanthoma or dermatomyoma, but differs from both in colour course, and distribution. In diagnosis, another error must be avoided, viz., that after injections of pilocarpine a spurious form of syringo-cyst-adenoma may be induced.

The microscopic appearance is peculiar. The mass appears to be composed of a number of tubercles formed of solid nests of epithelium, cysts with glairy homogeneous fluid contents.

The degeneration of the cysts and solid contents of the nests finally form a colloid substance which may contain many of the epithelial cells with granular contents. The first cellular nests and columns seem to arise from a thickening and hardening of the sebaceous glands and sweat ducts. From the pathology of the disease Neumann thinks the correct terminology is syringo-cyst-adenoma. He also emphasised the fact that the origin in his cases was not due to an abnormal or degenerate embryonic tissue, as many other observers had affirmed, but from primarily healthy tissue.

The notes in these cases were well illustrated by photographs as well as wet and dry microscopic preparations.

GASTRO-ENTEROSTOMY

Ullmann next exhibited a female, æt. 35, on whom he had performed gastro-enterostomy for a tumour in the pylorus. He connected the small bowel of the mesentery with the stomach, and closed the proximal end of the alimentary section. To the small intestine, which he connected with the stomach, he laterally connected the lower part of the duodenum to conduct the products of the pancreas and liver into the alimentary canal, so that digestion might not

suffer. The operation fulfilled the most sanguine expectation, and the patient recovered rapidly, and since the operation had increased in weight 17½ kilos, or 38½ pounds. Microscopical examination of the glands taken from the neighbourhood of the pylorus showed inflammatory infiltration. He compared these specimens with others taken from the neighbourhood of the cæcum, which he had removed for carcinoma, thus proving the carcinomatous condition of the remaining pylorus. He thought the success of this case disproved the opinions of Schuchard and others, who have affirmed that recovery is protracted in such cases, even if successful, when the carcinoma and glands are left behind.

DIRECT EXAMINATION OF LARYNX.

Schröter demonstrated Killian's method of examining the larynx and trachea as well as the bronchi by means of a tube directly, and not with the laryngoscope as hitherto. The part to be examined is lighted by means of a small electric lamp with a lens carried in the instrument itself. His object in using this instrument was an immediate one. He brought in a boy, æt. 12, who had the head of a pencil lodged in the left lung which could be seen by the Röntgen rays, but was beyond the reach of all instrumental arrangement. By cocaineising the trachea and bronchie and inserting this instrument he is hopeful of reaching the, at present, inaccessible fragment.

CONCRETIONS IN THE URINARY TRACT.

Zuckerkindl showed a few concretions taken from different parts of the urinary tract. The first were three stones removed from the urethra of a child æt. 3½. The second was a preputial stone taken from an old man. 73 years of age, who ten years previously was stung on the organ by a wasp, which produced a phlegmonous condition of the penis, with subsequent hardening of a small tumour about the size of an apple. The operation revealed two phosphatic stones in the preputial sac.

The third was a stone occurring in a female, æt. 55. For a long time this stone was caught in the lower end of the right ureter, where it formed a sac, it ultimately burrowed its way into the bladder, whence it was removed by crushing.

Whatever be the primary origin of these para-urethral stones, Zuckerkindl is firmly convinced that many of these crypts and fistulæ furnish the initial history of many of the nephritic and cystic stones met with in daily practice, which often reach a gigantic size before removal.

The Operating Theatres.

WEST LONDON HOSPITAL.

NEPHRO-LITHOTOMY.—Mr. BIDWELL operated on a man, æt. about 40, who had been admitted to hospital suffering from acute pemphigus. A sinus discharging pus was found in the left loin, and the patient gave the history that seven years before he had been operated on for renal calculus, but the wound had never healed. The present operation was undertaken when the acuteness of the attack of pemphigus had subsided. The kidney was exposed in the ordinary way by an incision of which the sinus was the centre, and seven calculi were removed from the body of the organ, not from the pelvis. A drainage tube was inserted, and the wound closed. Mr. Bidwell said the interesting point about the case was the probable origin of the pemphigus from

infection depending on the sinus in the loin; the infective origin of pemphigus, he said, was now well recognised, and an important point of its treatment should be the cure of any suppurating point.

It is satisfactory to note that the patient progressed satisfactorily both as regards his kidney trouble and the pemphigus.

ARTHRECTOMY OF KNEE.—The same surgeon operated on a boy, æt. 19, who had been admitted to the hospital with tuberculous disease of the knee. At first he had trouble in his knee ten years ago. This had subsided under rest and splints, leaving a perfectly useful joint. Eighteen months before admission the knee again became swollen, the swelling being most marked on the outer side. It had persisted in spite of treatment by splints and strapping. As the swelling was principally on the outer side of the joint, the inner side being seemingly not involved, the incision was made along the posterior border of the biceps tendon, and a cavity containing broken down cheesy material and granulation tissue opened up; the walls of this were dissected away, and the deeper parts scraped; it was then found that the cavity led directly into the knee-joint and that the cartilage at the lower end of the internal condyle was separated. A semilunar incision was therefore made in front of the knee-joint, its centre being below the lower border of the patella, and the skin flap dissected up as high as the upper border of the bone. The patella was then drilled vertically, was divided transversely with a saw, and the knee-joint opened up. The synovial membrane, which was infiltrated with tuberculous granulations, was dissected away from the external condyle and outer head of the tibia. The loosened cartilage over the external condyle was removed, and the bone scraped; nothing was done on the inner side of the joint as the synovial membrane had been replaced by cicatricial tissue, and there was no tuberculous deposit. The joint was thoroughly flushed with perchloride, and a stout silver wire was passed through the holes which had already been drilled in the patella, and tightened, bringing the edges of the divided bone in apposition, the ends of the wire being then twisted at the upper border of the patella. Both skin incisions were closed with horsehair, and a few points of silk worm gut, and the limb put up in plaster of Paris splints. Mr. Bidwell said the first point of interest was the relapse in the knee after apparent cure eight years before, showing that there was always a risk of return of tuberculous disease when it is not removed, and the case treated by rest alone. Another point, he remarked, was that, as the principal swelling was on the outer side of the knee, he had hoped that this was tuberculous infection of the bursa and had no communication with the joint; when he found that the articulation itself was affected he naturally decided to do an arthrectomy since the whole of the diseased area could not be removed by a lateral incision. He drew attention to the fact that the division of the patella gives excellent access to the joint, and ensures a perfect power of extension after wiring. He said he always drills the bone before dividing it, as this ensures accurate apposition of the two fragments. In wiring a patella, it is always, he said, advisable to twist the wire at the upper border of the bone, so that the resulting prominence afforded by the twist is well out of the way of pressure in kneeling. He

remarked that probably the case would not be dressed for three weeks, when the stitches would be removed, and the limb would be put up in plaster of Paris for another month; afterwards a moulded leather splint would have to be worn for about a year.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 13, 1899.

THE COUNCIL AND THE PRELIMINARY EXAMINATIONS.

THE attitude of the General Medical Council during the last two or three years in regard to the proposal to raise the standard of preliminary examinations had raised hopes on all hands that at last, after many weary years of half-hearted tinkering, we were within measurable distance of an improvement. Last session, the expediency of forthwith substituting the senior or higher grade examinations for the second and third-rate tests at present recognised as sufficient for purposes of registration by intending medical students, was referred to the Education Committee, with instructions to enlist the services of three experts in matters educational, and to report to the Council thereon. Early last week the anxiously expected Report was brought forward, but the conclusions therein arrived at will assuredly dash the hopes of all who take an interest in the problem of raising the status of the profession by ensuring that its members shall be persons of fair general education. It is well-nigh incredible, but we are assured on the authority of the three experts in question that the substitution of the higher grade examinations is at present impracticable "in view of the present state of secondary education in this country." The Committee endorse this report, and calmly ask the Council to acquiesce in conclusions which, if accepted, must inevitably have for effect to maintain the present miserably inadequate standard for an indefinite, but certainly protracted, period.

Is education then at such a low ebb in this country that schoolmasters cannot undertake to provide their scholars with a standard of general education superior to that exacted for the second class of the College of Preceptors or the junior local examinations of Oxford and Cambridge? Why, this admission justifies the harshest criticisms that have been passed on our national system of education by critics at home and abroad. It amounts to a confession of educational bankruptcy! From all corners of the Council Board arose cries of astonishment, disappointment, and dismay; indeed, Sir Richard Thorne was not wide of the mark when he described the report as "staggering," an adjective in the use of which Mr. Victor Horsley concurred. The Report gives no hint of the data on which these three experts arrived at their lamentable conclusion, fortunately perhaps, because the Council was manifestly unable to accept such far-reaching conclusions in the absence of any justificatory information. Are we then to consent to abandon for the present all idea of eliminating from the ranks of medical men the flagrant examples of illiteracy to whose existence attention has so often been called in connection with the competitive examinations for appointments in the Services, and also at the final examinations for diplomas? To deter the Council from entering upon any experiment of the kind, the experts threaten us with an immediate and considerable reduction in the number of candidates for registration, not perhaps an unmixed evil, even if their Cassandra-like utterances were fulfilled. The matter has been referred back to the Committee with instructions to furnish the data on which these conclusions were arrived at and to further consider the matter as a whole. We trust that before it again comes before them for discussion members of the Council will pluck up courage to do their duty to the public and to the profession in this matter *ruat cælum*.

THE HOUSING OF THE POOR.

THERE is no problem in the whole field of preventive medicine that demands more careful and immediate solution than the housing of the poor in our great cities. The rapid increase of population and the exodus of labourers from country to town has taxed existing urban dwelling space to its utmost capacity. The natural result is overcrowding, with all its attendant evils, a state of affairs that demonstrates among other things the urgent need of drastic land legislation. It has long been known that the rate of mortality has a close relation to the density of population, as shown by Dr. Ogle, when the number of persons to the square mile reaches or exceeds 400. On the other hand Dr. Newsholme insists with great reasonableness that the true density to be considered is the number of persons per room. So far as London is concerned it has been estimated upon the basis of the last Census that considerably more than half a million of the working classes, and about an eighth of the whole population, live in one- and two-room tenements, while the average occupiers per room is

three. In the parish of St. Pancras it has been officially stated that upwards of 60,000 persons are living more than two in a room. Bad as this state of things undoubtedly is there can be no question that it is surpassed in many provincial towns especially in such manufacturing districts as Lancashire and the Black Country. The brunt of the resulting mischief falls upon the producers of the national wealth, and in this way undermines one of the chief foundations of the prosperity of Great Britain. It may be argued that the local authorities are armed with sufficient means of coping with the evil, an assertion that goes beyond the facts of the case. It is true that there are considerable powers both as regards the control of overcrowding and of providing fresh housing accommodation. Against these potentialities, however, must be placed practical drawbacks that in no small measure render special legislative powers abortive. For instance, if vestries were to attempt to enforce the law against overcrowding, they would simply turn into the street whole families who would be unable to find other accommodation. So too with closing orders against insanitary property. Where the vestry does its duty as often as not landlords leave the condemned property alone and do not attempt to rebuild, because the source of their profits lies in the overcrowding, and the original tenant cannot afford to pay a high rent unless he is able to rack-rent the sub-tenants at a figure that can in turn be made up only by overcrowding. Indeed, with a knowledge of the fact that there is no accommodation available for displaced inmates magistrates often refuse to make closing orders, that is to say, admittedly insanitary premises are allowed to be crowded to excess in the heart of the greatest and richest city in the world and that, moreover, by express legal sanction and in contravention to the written law. For all that one cannot quarrel with the common sense humanity that guides the action of the magistrates, it is rather to the state of the law and the action of the local authorities that one must look for future reforms. As already said the laws relating to the tenure and sale of land lie at the root of a great deal of the evil. The want of cheap transit prevents the migration of workmen to outlying districts where land is cheap. The London County Council has the power of demolishing insanitary areas and providing for the displaced population. Unfortunately the new houseroom may be pitched in any part of the metropolitan area, however distant and there is no obligation to furnish *interim* accommodation while the fresh buildings are being erected. This difficulty, however, is only one of many that beset the whole problem. For instance one of the means by which vestries evade the regulation of houses let in lodgings is to fix a low maximum price, which they are entitled to do, at which control shall be exercised. Supposing half a crown be fixed as the limit then it is clear that the majority of lodgings in that particular district will be at once excluded. Then, again, a fact that must be faced is the decrease in common

lodging houses, and the rapid increase of ill-regulated shelters, neither of which should be wanted to any great extent were casual Poor-law relief administered in a broad and liberal spirit. Another point is that excessive hours of labour add to the pressure by making residence on the spot a necessity. Coming to remedies, the vestries should be urged to do their duty in enforcing sanitary standards and in regulating houses let in lodgings. Municipal bodies should follow the example recently set by the London County Council in closing unhealthy areas and building houses to accommodate the displaced population. A great impetus might be given in that direction if the Government would advance at a low rate of interest and a long term of repayment the money necessary for rehousing schemes. Nor can it be doubted that the general education and enlightenment of the people on these matters must precede any great measure of reform. Lastly, the reconstruction of the laws affecting land seem to be an imperative condition. Of anything like a thorough handling of this question of the housing of the poor, and certainly not the least important of the points that demand attention in that quarter is the taxation of ground values.

THE LONDON COLLEGES AND THE COUNCIL.

THE uncompromising attitude of the London Colleges in regard to the authority of the General Medical Council to control the recognition of schools and other teaching bodies by the Colleges as suitable for imparting scientific teaching to intending medical students, gave rise last week to an animated debate at the Council, in which the representatives of the Colleges were obviously at variance with the great majority of their colleagues. It will be recollected that the London Colleges had, for three years past, accepted as qualification for their examinations courses of "instruction" in physics, chemistry, and biology, delivered to school boys in grammar schools and other non-medical schools long before the boy became a medical student, and they claimed that a year supposed to have been occupied with such courses should be accepted as one of the five years of medical study enjoined by the Medical Council. That Council and everyone outside these Colleges regard this proceeding as a palpable attempt to evade the regulations, and the Council has said so in no uncertain terms; but it has been met by the Colleges, not to say with hostility, but with truculence and discourtesy. Their answer to the Council is that they "decline to recognise the requirement that scientific institutions, where medical study is commenced, should be approved by the Medical Council." This is an ultimatum which it is quite obvious the Council cannot put up with, because it amounts to a deliberate repudiation of its authority to supervise study, not in these subjects alone, but in any of the subjects of the curriculum. The ground taken by the Colleges in justification of their refusal to admit the authority of the

Council to intervene in this matter is based on the fact that no clause in the Medical Act specifically gives this power. If, however, the sciences are admitted to form part of medical education the conditions under which they are taught must obviously fall within the competence of the Council. It seems absurd to pretend that the Council does not possess the right to specify the conditions under which they will recognise particular courses of study, for, were it otherwise, the whole system of examination would be reduced to a farce. It is to be presumed that the Colleges have had good legal advice before assuming this, but certainly, we fail to find any legal justification for the position which they have assumed. As to the power of the Medical Council to define the sort of instruction which it will recognise, the 4th Clause of the Medical Act of 1886 says:—"If at any time it appears to the General Council that the standard of proficiency in medicine, surgery, and midwifery, or in any of those subjects or any branch thereof, required from the qualifying examinations held by any of the Bodies . . . is insufficient, the Council may make a representation to the Privy Council which . . . may by order declare that the examinations of such Body shall not be deemed qualifying examinations for the purpose of registration." The only question which can be discussed seems to be whether Chemistry, Physics, and Biology form part of the subjects essential to competency in medicine, surgery, and midwifery. If not it is competent for every licensing Body in the Kingdom to wipe these subjects out of the curriculum, and we have no doubt that they will do so. The Council, however, possesses ample means of enforcing its resolutions, and should the matter ultimately be referred to the Privy Council there can be little doubt as to the result. As, after all, the Colleges do not stand to gain anything by protracting their obstinacy, we may hope that wiser counsels will prevail, and that they will avail themselves of the earliest opportunity of abandoning an untenable position. They may, perhaps, feel themselves strong in the letter of the law, but it is manifest that they have no support in public opinion considering that, in the division which was taken on this Council, they scored but one vote—that of the representative of the London College of Physicians—against twenty-two votes cast in support of the policy of the Council.

Notes on Current Topics.

A Magistrate upon Medical Certificates.

THE Stipendiary of Cardiff, Mr. North, may be congratulated upon having the courage of his opinions so far as the value attachable to medical certificates produced in defence of School Board prosecutions for non-attendance. The exciting cause of his remarks upon a recent occasion was the putting in of an undated certificate stating that a child who failed to attend the Llanwonno School was suffering from bronchial catarrh. The magistrate thereupon said that doctors' certificates given

in certain cases were simply waste paper. Without a detailed knowledge of the facts it is impossible to form a sound opinion as to this extreme attitude, but if it were dependent on the absence of a date from the document, then we think the medical man who signed it should have been afforded an opportunity of offering an explanation. Some clue to the inwardness of the matter may perhaps be obtained from the request of the prosecution, which asked his worship to say that certificates delivered for the first time in Court should be taken no notice of. If these certificates, it was urged, were delivered at the schools or given to the attendance officer they would receive due attention, and the parents would not be summoned. There seems to be reason in this view of the question. It will be well for medical men to grant certificates only where a case is absolutely above suspicion, and to refuse altogether where the document is required simply to spring in Court upon a prosecuting Board. Members of the medical profession are apt to act from the heart rather than the head, but it would be a thousand pities if from abuse of sheer good nature they were to destroy or lessen the value of medical certificates produced in Court for various purposes.

The Way the Juvenile Student Has.

EVERY one must thankfully acknowledge the great improvement which the last quarter of a century has witnessed in the demeanour of the student. Bob Sawyer and Ben Allen, who were very trying realities in the early fifties, have become extinct, and, as a rule, students are now endowed with sufficient intelligence and self-respect to feel that there is no fun in making fools of themselves and bringing their class into public contempt, although even those who preside over them like to see them good humoured and hilarious. We suggest that, as a reform in the conduct has been voluntarily effected by the great majority of students, it is time that the rowdy minority should be restrained from making nuisances of themselves by disturbing important public functions. We say unhesitatingly that the system of converting such a function into a disreputable bear garden is played out and ought to be stopped by those in authority out of respect for their own offices and for the prestige of the institutions over which they preside. The idiotic pandemonium which marks the conferring of degrees in most places is confessedly a nuisance to every one, so much so that many thinking people stay away to avoid it, but it is tolerated as many other abuses now departed were tolerated because it is an old custom, a reason which in these days has ceased to have any force. We urge that it is a most distressing sight to see an honoured old gentleman attempting to address such an assembly while he is bombarded with peas and crackers, and his voice drowned by the screeching rowdiness of a number of the audience who can think nothing interesting save their own inane jokes and howls. These observations are evoked by the stupid and annoying conduct of some of the students of the

Queen's College, Cork, on the occasion of the recent triennial visitation of Mr. Justice Holmes, Sir Thornley Stoker, and Dr. Moore. We are told that the baby-minded men students converted the notice boards into banners, and, having procured a garden hose, saluted the President's residence, where the visitors were lunching, with discharges of water. A hunt was then organised, a stuffed tiger belonging to the natural history museum being commandeered for the purpose, and during the sport several botanical specimens were uprooted. An empty prison van was next attacked, overturned, and the driver seriously injured. In the evening these students diversified the entertainment by getting up a street riot in which they were compelled to fly ignominiously before the incensed mob. We submit that, if this sort of contemptible rowdiness cannot be avoided, visitations and capping ceremonials should be held *in camera*, or that only carefully selected ticket-holders should be admitted thereto. Really it is desirable that the feelings of the respectable people amongst the audience on such occasion should be consulted.

The Reciprocity Question.

WITH a dilatoriness to which the Council has accustomed us the pressing question of reciprocity of medical practice in regard to Italian practitioners has again been postponed, under the fallacious protest of ascertaining whether the Italian Government contemplates any change in existing arrangements as regards the practice of medicine in Italy by British practitioners. In the interest of the not inconsiderable number of British practitioners in that country some action on the part of the Council was imperatively called for, but in deference to the natural distaste for hypothetical foreign competition action has been postponed. This is the more regrettable seeing that Italy is alone in according generous treatment to our fellow countrymen in this respect, and the opportunity of cementing an accord on this point may at any moment be lost. We have no sympathy with those who, like Sir Christopher Nixon, deprecate any alteration in existing regulations "for the convenience of foreigners." He and they lose sight of the fact that reciprocity is a measure which must always tell in favour of the ubiquitous Englishman. We must deprecate also the narrow-minded suggestion to introduce a clause into the Medical Act to restrict foreign medical men to practice among their own countrymen, a provision which could not possibly work well and would be virtually impossible to enforce.

American Army Surgeons' Grievances.

THE assistant surgeons of the United States army who served during the war with Spain appear to have some ground for complaint as to their treatment by the Government. At any rate, they have called a mass meeting in New York for the purpose of forming an organisation and of obtaining legislation from Congress fixing their legal status as officers

of the army. It is claimed that the burden of the medical and surgical work of the Spanish war fell upon about a thousand acting assistant surgeons, who were exposed to all the dangers of wounds and disease incurred in that campaign. They were overworked, and had only the shadow of rank and authority, while a part of their already scanty pay was withheld by the rulings of treasury officials. The main ground of complaint, however, relates to their present standing in the army. They say that in accordance with an agreement made at the time of their enlistment, the acting assistant surgeons were to have received the rank and pay of first lieutenants on the staff when mustered out, but that this has never been accorded to them, and their legal status as officers in the army has, in consequence, been left undetermined. At the forthcoming meeting it is proposed to ask of the legislature that each acting assistant surgeon receive preference for appointment over those who have not had previous service in the medical corps of the army or navy or the marine hospital corps. Without hearing the arguments on both sides of the question it is impossible to form a sound judgment, but it certainly appears that in the present instance the United States Government have not acted generously to the medical men who so freely offered their services in time of need. Jealousy of the medical branches of the military service is not unknown in other countries, but it is to be hoped that the United States will not allow her laurels to be smirched with black ingratitude to the men who did their duty as heroically as any who graced the annals of their country during the late war.

The London School Board and Underfed Children.

FOR some time the London School Board have had under discussion the subject of providing meals for the young scholars, who are considered to be underfed. The idea, of course, may be regarded as excellent from a philanthropic point of view, and upon this basis we should like to see it accomplished. But it is quite another matter to look to the ratepayers for the means of carrying out the scheme. This was entirely the view taken at the last meeting of the Board, and it has now been decided to reconsider the question for the purpose of seeing what can be done by voluntary effort. Clearly, there would be great danger of abuse if free meals for underfed children were promiscuously provided by the ratepayers. Much as we may sympathise with the poor little mortals who have to work hard at school without having enough to eat, we nevertheless think that it is not the duty of the Board to deprive the parents of the responsibility of providing dinners for their offspring. With free education and free dinners, generously afforded by public money, poor parents at this rate will soon be able to have children who will cost them nothing. On the other hand, we doubt whether any self-respecting parent would permit a child of his to accept a free meal; consequently the free meals would probably be given to the children of parents who would

be only too glad of the opportunity of shirking their parental duties. By this means worthlessness would be encouraged, and a premium placed upon idleness.

More Influenza.

WE learn with regret that there is every probability of a renewal of the influenza outbreaks which for years past have exacted a heavy toll from the population of the United Kingdom. Numerous reports of attacks in schools and elsewhere have come to hand from both London and the provinces. Fortunately, the epidemic seems to be, on the whole, of a milder type than in former years. Although influenza does not confer subsequent immunity from the disease, it nevertheless seems to modify the course of the malady in later attacks. It is difficult to judge of the extent or severity of an epidemic of this most subtle and infectious complaint from mortality statistics, because many of the resulting deaths are due to remote and indirect causes. From a recently-issued bulletin of the Health Department in Chicago, we learn that this pest of mankind has been "permanently domesticated" since 1891. It is to be feared that the epidemic wave of influenza has not yet rolled away from our own country. Indeed, in the face of the present somewhat alarming signs of recrudescence, it has been suggested that the Home Office should be asked to take into careful consideration the advisability of requesting the local authorities throughout the country to add influenza, for the time being, to the list of notifiable diseases.

The Decadence of the Army Medical Service.

LAST week Surgeon-General Hamilton, lately P.M.O. for Cape Colony, gave, when distributing prizes at the Volunteer Ambulance School, some instructive facts as to the decadence of the Army Medical Service. He said that when he entered the Service forty years ago the total strength of medical officers was considerably over 1,100. At present the executive ranks barely numbered 800, a long way short of the recognised establishment. During the same period the European Army of England had been increased by some 70,000 men, so that with this large increase in strength we had 300 fewer officers to do the work. Out of this number of 800 medical officers there were 408 on ordinary foreign service, 240 in South Africa, and about 100 effective officers in the United Kingdom. When the two further divisions now being mobilised were provided for, the Royal Army Medical Corps would have closely approached its vanishing point in the United Kingdom. It had been already found necessary to supplement the medical staff in South Africa by 70 civil surgeons, and he believed all, or nearly all, of the available retired pay officers had been called back to duty. It was quite evident there was no lack of military ardour among the members of the medical profession as was proved by the fact that seventy civil surgeons were now serving with our troops in the field, but it was equally evident that the Royal Army Medical Corps was not popular in the medical schools. This

falling off in the strength of one of the most important departments of the military service of the nation is, obviously, due to the policy of "snub" adopted by the "my military advisers" towards the medical officers. Surgeon-General Hamilton said that there was satisfactory proof that everything that was possible was done in South Africa for the care of the sick and wounded, the medical staff working most heroically in the field under the greatest difficulties. Sir George White had spoken most kindly and sympathetically of the labour of medical officers in the late Frontier War in India, and said he had seen reason to recommend more of the medical officers for the Victoria Cross than all other branches of the Service put together. This gallant officer's recommendations, Surgeon-General Hamilton observed, were set aside by those in power in our War Office, and the many acts of valour performed by medical officers in that campaign had gone unrewarded.

The Surgeoncy to the City of Dublin Hospital.

THE succession to the surgeoncy of this hospital, vacated by the death of Mr. W. Wheeler, is the subject of speculation among Dublin hospital surgeons. It is rumoured that three former house surgeons of the hospital will be candidates, besides others, and that there is also a proposition to appoint an assistant surgeon, either in addition to or in substitution, temporarily, for the surgeon. As we have always been strongly in favour of the system of promotion from the ranks in hospital appointments, we think that the candidate who had served the hospital in the minor capacity should have a prior claim to the higher position, if his record, in the minor rank, has been good, and we strongly object to the pitchforking of any untried competitor into the responsible charge of cases and the performance of operations. Perhaps it may occur to the administration of the institution that the sick poor who enter the hospital ought to be thought of when a practitioner competent to treat them is for selection.

The Harvest of the War.

THE first arrival of sick and wounded from the seat of war by the *Sumatra* last week included two wounded officers and 126 invalided men, who were mostly the victims of some tropical disease, such as dysentery and malaria. But light in casualties as this preliminary batch is, we, nevertheless, shall have to be prepared for some very heavy consignments of wounded men later on. The Boer marksmen have not come up to the standard expected of them, so far as the accuracy of rifle fire is concerned, otherwise it is certain that the casualty lists for the various engagements already fought would have been greater on our side than they have proved to be. From all accounts, however, there seems to be every probability that the war will yield an enormous total of wounded soldiers which will tax the resources of the hospital accommodation in South Africa to the fullest extent. Hence, no

doubt the authorities will endeavour to help lessen the pressure on the beds by regularly transferring as many of the wounded as possible to this country. Of the two wounded officers already referred to, one was injured in the head by the bursting of a Boer shell early in the battle of Elands-laagte, and the other was suffering from an injury to the right arm caused by a Mauser bullet. The latter case will presumably require some surgical treatment inasmuch as very acute suffering, showing some nerve lesion, is still being experienced by the officer.

Senile Parotitis.

It is said by some authors of text-books on medicine that parotitis in old persons may occur, but it so happens that medical literature contains the records of only one case, referred to by Pepper. Another case, however, has just been published by Walcott in the *American Journal of the Medical Sciences*. The patient was a retired practitioner, aged ninety years and a-half, and the attack began to develop one day after he had been working in his garden. The right parotid became rapidly swollen, and exceedingly painful. The swelling ultimately extended to such a degree that the right ear was completely closed, and the ear occupied the centre of the inflammatory enlargement. Despite active treatment delirium supervened; the heart also began to fail, and on the fourth day of the commencement of the attack the old patient died. The fatal termination in this case is significant when compared with the other recorded case, which also proved fatal, in an old lady of eighty-four. The typical signs of parotitis were present in both, and there seemed to be no grounds for doubting the correctness of the diagnosis. It is, however, impossible to believe that cases of the disease, other than these two, have not been met with. Rare in old age as the affection undoubtedly is, it must nevertheless be true that the disease has occurred upon former occasions, but without the cases having been placed on record.

Unsound Fruit Prosecutions.

THE seizure last summer of large quantities of fruit at certain South London jam factories always seemed more or less a counsel of perfection. From what we know of the process of manufacture of the wholesome edible concerned it may fairly be presumed that sterilisation of all harmful microbial life is connoted. That view of the case, however, did not commend itself to the prosecuting sanitary authorities, and to the magistrate and the judge who tried the case. The sequel to the heavy penalties then exacted has come in further legal proceedings against the Covent Garden merchants who consigned the fruit in the first place in an unsound state to the jam factories. The practical outcome of these prosecutions has been to place a serious check on a large and flourishing branch of local industry, while, on the other hand, it is doubtful if the public is a penny the better off. The zeal of the sanitary inspectors and of the Medical Officers of Health, who are nominally in charge of

these matters would be more wisely directed, in our opinion, against the thousand and one adulterations that cheat the pockets and undermine the health of the community on all hands. Yet the prosecutions for this class of offence are ludicrously inadequate. The very terms of appointment of the public analysts, as we have recently pointed out, in many cases emphasise the act that any extensive analysis of food and other adulterations was never contemplated by the appointing authorities. Otherwise no sane vestry would hand over this exacting work to a man who held similar posts in connection with, perhaps, two or three civilian and half-a-dozen distant county districts. Where are the Home Office and the Local Government Board, who share the responsibility of the present arrangement?

School-Life and Constipation.

THE want of consideration shown by careless and bashful schoolmasters and mistresses to the physical needs of their scholars is doubtless responsible for the constipation which, we are assured, is so prevalent in schools. No special measures are taken to ensure attention to these fundamental details of life, the closets are for the most part cold and decidedly uncomfortable, and every difficulty is placed in the way of scholars who experience a desire during the progress of the lessons. A French practitioner, Dr. Gripat, recently published an article insisting on the necessity for greater attention on the part of those who have charge of young persons in this respect, and he goes so far as to suggest that a register should be kept, in which every scholar would be constrained to record the working of his economy. Certainly a little systematic drilling would greatly tend to regularity of the intestinal functions, and much time would be saved by accustoming children to avail themselves of the intervals between lessons, instead of waiting until class time for the need to become imperative. It is obviously as important, from the point of view of scholastic hygiene, to ascertain the integrity of these functions as to examine the throat or the eyes, for unless these functions are regularly and adequately discharged, the capacity of the student to profit by the teaching must be greatly impaired.

Medical Practitioners in Japan.

It seems almost inconceivable that a dearth of medical men should exist in any part of the world save in parts far removed from civilisation. But the curious fact is that in Japan the number of medical men available for the population is far below the requirements. In discussing this matter the last issue of the *Sei-i-Kwai Medical Journal* remarks as follows:—"At a time when the numerical insufficiency of medical practitioners has become a chronic complaint in this country it is gratifying to find that their number has been appreciably on the increase during the past few years." The journal in question, however, subsequently shows that the returns for the last five years only show an average annual increase of 50 qualified men. It seems remarkable that more young men are not

induced to join the medical profession in Japan. The question of any natural incapacity for the work cannot be one which acts as a deterring element, for Japanese medical students are by no means unknown in the British medical schools, and it is also tolerably well known that some of these students have displayed more or less brilliancy in their work. How is it, then, that Japan suffers from a dearth of medical men?

Unqualified Dispensers.

As we foretold, the Council have not thought fit to take any action in regard to the employment of unqualified dispensers by medical practitioners. The special committee appointed to investigate the matter simply endorse the reply already forwarded to the Privy Council by the Executive Committee, thereby intimating that they do not consider the subject to be one calling for any special action. The question is one of far-reaching importance, but we can quite understand the reluctance of the Council to intervene, unless constrained thereto. The whole fabric of medical practice is based on the employment of unqualified dispensers, and any modification of existing arrangements would entail what would almost amount to a dislocation. We doubt whether public opinion is, as yet, sufficiently alive to the drawbacks of the present system to insist on a change. The bogey of accidental poisoning, trotted out by pharmaceutical agitators for trade purposes, has not had the desired effect, and, as far as one can judge, practitioners are not likely to be molested in this respect for some time to come.

"One Man—One Billet."

UNDER this heading the *Australasian Medical Gazette* offers some remarks in its October issue respecting some recent appointments conferred upon Dr. Leith Napier, who was at one time well-known in gynaecological circles here. The South Australian Government, in addition to the posts already held by Dr. Napier, have just appointed him Assistant Colonial Surgeon, and Senior Assistant Medical Officer at the Adelaide Lunatic Asylum, and have also made him a member of the South Australian Medical Board. These additional marks of favour seem to have caused some resentment in the Colony, which our contemporary takes upon itself to voice. But it is only natural that the Government should avail itself of opportunities to show its appreciation of the services which Dr. Napier at one time rendered it; and if he is now a pluralist, it is not improbable that a good many of his profession in the Colony would only be too glad to be in his shoes.

The Branch Councils.

UNLESS the Branch Councils are to become inanimate bodies it is evident that steps must be taken to rehabilitate their financial position, a contingency which has never been favourably entertained by the General Council. The matter, however, is forcing itself on their attention, and a slight step in the direction of redistribution has just been taken by referring the matter to a committee for future report

No good can come of taking further legal opinion thereupon. The Council must by this time be perfectly cognisant of the situation, and it only remains for them to agree to proceed to draw up a plan providing funds for transacting business in the two departments of the kingdom, in which the Branch-Councils are specially afflicted by impecuniosity.

The Plague in England.

THE introduction of the plague into Great Britain dates from mediæval times, and it was most likely identical with the terrible scourge known as the "Black death." It was epidemic in this country for centuries until its last great outburst in 1665, after which it retreated to the European continent, where it lingered fitfully in certain countries until 1841. In Asia it has always been endemic with constantly recurring epidemic outbreaks. The mortality from plague in the 17th century was terrible, as shown by following figures taken from the London bills of mortality:—

Plague deaths—Total.				Deaths per 1,000 from all causes.	
1603	30,561	...	819
1625	35,417	...	652
1636	10,400	...	445
1665	68,596	...	705

The cessation of the scourge in England was no doubt due almost entirely to the disinfection of the chief centre of population by the Great Fire of London. The march of science, however, has made it practically impossible for the plague to get a foothold in any country that maintains a decent average of general sanitation. The increase of knowledge regarding its etiology has been well expressed by an authority upon these matters, Dr. Newsholme, who says: "Plague is an infectious filth disease, fostered by destitution, overcrowding and lack of ventilation, and due to a bacillus which lives in the soil, and attacks lower animals; mortality in rats has been often observed before outbreaks." In the disappearance of plague we find an object-lesson of what will one day occur with all infectious diseases. Nothing in that direction is impossible to the energy and resource of modern prevention.

A Medical School for Assam.

By his will the late Brigade-Surgeon John Berry White left 50,000 rupees for establishing a medical school for the Assamese students. It is expected that the school will be opened in June next.

Preservatives in Food.

IT will be observed that almost all the evidence given before the Departmental Committee on food preservatives turns upon the fact that boric or salicylic acids or other similar preservatives are present in most of the preserved foods which the public consume. The sophistication is now confessed, but it does not seem to us that it touches the real question, which is whether these preservatives are present in any quantity sufficient to injure the health of anyone who consumes a reasonable amount of the food. We should like to know how many pounds of butter, or gallons of milk, or hams it would be necessary to consume if one wanted an injurious dose

of any of these preservatives. It is a very "white lie" to say that a food is not adulterated if it contains no more than a homœopathic dose of an almost inert preservative.

From Sewage to Peppermint.

THE cultivation of peppermint on sewage farms seems to be a profitable undertaking, as proved by the experience of the Sutton Urban District Council. Nothing, however, could more eloquently—or satisfactorily—show the marvellous concatenation of changes which Nature can effect, that that by means of foul smelling sewage, an odorous product can be evolved which enjoys several spheres of popularity. The authority above mentioned, will by next year have six acres of their sewage farm under peppermint cultivation.

Inebriate Asylums.

FOR the present it appears that the provision of asylums under the Inebriate Act of last year must devolve upon the wealthy English communities, and we observe with satisfaction that the London County Council has appointed a special committee to organise the system. In Ireland, as yet, there is but one such asylum, situated at Ennis, and to it there is no admission save for a criminal sent in by the magistrates. Everything must have a beginning, and we expect that these beginnings will eventuate in the general adoption of the principle of the Act and its system.

War Supplies.

SOME idea of the vast proportions of the supplies required by the War Department for a campaign like the present may be judged from the fact that it has provided on the basis of a four months' campaign for 6,000 lbs. of carbolic powder, 20 tons of chloride of lime, 10,000 gallons of Izal, and 10 tons of Macdougall's disinfecting powder.

THE treasurers of the Middlesex Hospital have received £100 from "Research" in response to their appeal for the establishment and maintenance of the New Cancer Research and Laboratories, recently instituted for the investigation of the cause of cancer.

PERSONAL.

VISCOUNT PORTMAN has contributed a further donation of £1,000 in aid of the building fund of Queen Charlotte's Lying-in Hospital.

THE EARL OF LEICESTER, President of the Norfolk and Norwich Hospital, has promised a further sum of £10,000 in aid of the funds of the institution, making in all £15,000.

THE Council of King's College, London, have appointed Professor N. J. C. Tirard, M.D., to the Chair of Medicine vacant by the resignation of Professor J. Burney Yeo, M.D.; and Dr. W. A. Turner to be an Assistant Physician at King's College Hospital.

DR. CHRISTOPHER, accompanied by Dr. Stephens and Mr. A. Pichels, having been selected by the Royal Society, have left by the s.s. *Bakana* for the West Coast of Africa

to study the question of the prevention of malaria. They work under the auspices of the Liverpool School for Tropical Diseases.

MR. J. S. WOOD, formerly Secretary to the Chelsea Hospital for Women, has given a donation of £100 to name a bed "In Memoriam," and the council, being in urgent need of funds, suggest the naming of beds in memory of those who have fallen in battle in South Africa.

A CORRESPONDENT informs us that Dr. C. A. Stark, who was recently killed at Ladysmith by a Boer shell, was a graduate of Edinburgh University, and had been in practice at Cape Town for the last twelve years. On the outbreak of the war he at once volunteered for medical service, and was among the last batch of officers to enter Ladysmith before the investment.

DR. MORGAN DOCKRELL was last week presented with a service of silver plate and an illuminated address, which had been subscribed for by a large number of medical men in recognition of his action in the Law Courts to prevent the unauthorised use of his name in advertisements, and as a *solatium* in the heavy expense incurred in connection therewith, as recently set forth in these columns.

In addition to Mr. Arthur Chance, whose candidature for the seat on the Council of the Royal College of Surgeons, Ireland, vacant by the death of the late Mr. Wheeler we announced last week, Mr. Charles Bent Ball, Regius Professor of Surgery in the University of Dublin and Surgeon to Sir Patrick Dun's Hospital has offered himself to the Fellows as a competitor. Mr. Ball has served recently as a Councillor, and retired from that position in order to seek the Vice-Presidency of the College.

MEDICAL SOCIETY OF LONDON.

At the meeting on Monday evening last, Dr. Rolleston and Mr. Turner contributed notes of two cases of ascites due to hepatic cirrhosis treated by the artificial production of peritoneal adhesions, a method introduced by Dr. Drummond and Mr. Morison, of Newcastle. Case 1. A man, aged 52, had been twice tapped for ascites. The abdomen was opened in the right semi-lunar line, and the opposing surfaces of the cirrhotic liver and the diaphragm rubbed and scratched, the liver being then fixed by a kangaroo tendon to the abdominal wall. The patient recovered from the operation but no improvement followed. Case 2 was that of a man of 45, who suffered from hæmatemesis with ascites and oedema of legs. The liver was exposed by a 5 inch incision parallel to, and 1 inch below, the right costal margin, the surface was scraped and the omentum was brought up between the diaphragm and the convexity of the liver, and fixed in position by a kangaroo tendon including the edge of the liver, the omentum, and the parietal peritoneum. This patient steadily improved and had had no further ascites. The author pointed out that the benefit of the operation was not due merely to reducing the portal blood pressure by opening up a collateral circulation (for this, if carried to its logical extreme, led to an uræmic state), but to an improved blood supply to the liver *via* the adhesions.

Dr. Weber thought a high specific gravity of the fluid might indicate the presence of inflammation, in which case tapping might effect a cure.

Dr. F. J. Smith advocated laparotomy in place of the ordinary brutal paracentesis. He mentioned two cases in which the fluid was blood-stained and asked what this might mean.

Mr. Bidwell mentioned two unsuccessful cases of operation for cirrhotic ascites, and Mr. Wallis mentioned a case of enormous ascites in which permanent relief had followed several tapplings.

Dr. Ewart said they required to know how to tell beforehand whether the case was one of cirrhosis or not, and mentioned a case of ascites supposed to be cirrhotic which proved to be due to calcified pericardium.

Mr. John D. Malcom read notes of "Fifty Successful Consecutive Cases of Ovariectomy, recorded three years after the operation." He commented on the difficulty of comparing statistics, 25 of his patients were in almost perfect health, 7 could not be traced, 7 others had little to complain of, and three were dead. He urged that an early operation should be performed whenever possible, delay not being justified by present good health of the patient. He attributed most of his fatal results directly to delay in operating.

MR. BRUDENELL CARTER—AN EXPLANATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I find certain statements in your journal of the 6th inst., the correctness of which I am compelled to question, and which are made with reference to a speech which I addressed to the Medical Council on November 28th. You say I complained of the "medical journals" for habitually suppressing replies to speeches adverse to me, and you deny the justice of this reproach as applied to yourself. If you will refer to the *Lancet* report of my speech, in the number for December 2nd, page 1,561, at the foot of the first column, you will find that charge did not extend to you. You say also that I did not "succeed in explaining away my behaviour in respect of the prosecution of the late Mr. Hunter, and that if I were really unaware of the fact that Mr. Hunter was a licentiate of the Society of Apothecaries that was a serious piece of negligence on my part." If you will refer to the *Lancet* report, in the upper portion of the column already reported, you will see that I made no attempt to "explain away my behaviour," in relation either to the Hunter case or to anything else. You will also see that everybody concerned was perfectly aware that Mr. Hunter was a registered medical practitioner, and that proceedings against him were recommended by the Penal Cases Committee on the ground that, being a registered medical practitioner, he had nevertheless used titles which he did not possess in any registrable form. He asserted his right to use these titles (those of Doctor and M.D.), and expressed his readiness to "fight to the end" in defence of his claim. The proceedings were recommended by the committee for the purpose of determining an unsettled legal question, and of determining it in the case of a defendant who expressed his readiness to fight. The question was, whether a registered practitioner who, in addition to his registrable and registered qualifications, possessed another which was not registrable, was entitled to use the latter as part of his ordinary professional designation. The recommendation of the committee to the Council was that this question should be settled by legal proceedings. If any members of the Council did not know that Mr. Hunter was qualified and registered, such want of knowledge was not the fault of the Committee, and might, perhaps, not unfairly be described as "a serious piece of negligence," with regard to business the precise nature of which was clearly stated. I presume it will hardly be contended that, if a practitioner commits an act of doubtful legality, it becomes the business of the representative, in the Council, of the body from which his qualifications are derived, to endeavour to prevent the doubt from being cleared up. That the proceedings ultimately took a form not anticipated either by the Committee which recommended them, or by the Council which ordered them, was a highly unfortunate occur-

rence; but it was brought about by the fact that the legal advisers of the Council acted upon a view of their instructions, which the Council itself, or at least which I, as an individual member of it, had not so much as contemplated.

I am, Sir, yours truly,

R. BRUDENELL CARTER.

31, Harley Street, W.,
Dec. 9th, 1899.

THE SOCIETY OF APOTHECARIES OF LONDON

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I was amused to read the report in your columns of what occurred at the recent meeting of the General Medical Council, when Mr. Brudenell Carter and Mr. Victor Horsley were allowed to be heard. It did not certainly appear very creditable to Mr. Horsley to be called to account for speaking of the Society of Apothecaries in public in the way he had done, apparently assuming without inquiry that his damaging statements were facts instead of the fallacies which he subsequently was compelled to admit them to be. But now it is evident there is great need for the three great societies which control the licenses of medicine and surgery in London, to work in greater harmony than they have done for some time past. In a recent article you drew attention to the difference between the Conjoint and the L.S.A. examinations and licences; and I think that in the interests of our profession, our students, and the public such rather discreditable controversies as occurred at the Medical Council should not be encouraged. It brings the medical profession into public discredit when such displays occur, and the impression is produced that there is a great need of reform in medicine, as in some other lines of professional life and business.

I am Sir, yours truly,

F.R.C.P.

INCONSISTENCIES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—A large number of persons (call them "benevolent old parsons and impressive old ladies" if you think it accurately describes our great society) have united themselves together to oppose what we consider the cruelties practised in physiological laboratories. This is a very clearly defined object—in no sense necessarily involving the work of protecting animals from ordinary forms of cruelty such as those of sport or of the cattle-trade. The excellent and powerful Royal Society for the Prevention of Cruelty to Animals occupies itself with cases of ordinary cruelty. It was felt that a special organisation was needed to deal with vivisection, because of the many technical matters involved, but it is no more the office of our society to deal with such questions as those with which the Royal Society for the Prevention of Cruelty to Animals concerns itself than it is the duty of the War Office to interfere with the adulteration of milk or the spread of ritualism in our churches. As a fact, a great number of our subscribers are individually supporters of the Royal Society for the Prevention of Cruelty to Animals, the Society for Prevention of Cruelty to Children, and the like. Your correspondent, "Mawworm," says we devote ourselves to "mendacious attacks on the medical profession for putting a hypodermic injection under the skin of a frog." Does he really believe that such an agitation as that of the Anti-vivisection Movement could be maintained in this country, America, and Germany on the strength of hypodermic injections on frogs? Has he read Dr. Crill's "Surgical Shock," or even studied the "Journal of Physiology"? That physiologists have done very cruel things in this country was proved by the Royal Commission, that they do very cruel things in Continental laboratories now is not, so far as I am aware, disputed by English physiologists. The question at issue is, does the Vivisection Act of 1876 adequately protect the animals? In a debate on the subject at University College, London, in which I had the honour to take part recently an opponent, said, "I concede you

seven-eighths of your case," that is to say, the pain involved, the paucity of results to practical medicine, &c., "and I take my stand on the ground that what is useful to science is moral." This is the dignified attitude of a competent judge of our question. It is too late in the day to treat us either with ridicule or discourtesy.

I am, Sir, yours truly,

EDWARD BERDOE, L.R.C.P.Ed., M.R.C.S.

December 1st, 1899.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am a strong anti-vivisectionist, but I am not averse to "Mawworm" pointing out that all those who object to torturing, in the alleged interests of science, should openly and uncompromisingly denounce the cowardly cruelties practised by sportsmen. Last Friday, for instance, the Queen's Hunt turned out a tame deer at New Lodge, Winkfield, and more than a thousand people graced the function. This wretched animal was harried about the country till it actually fell and died by the bank of Silwood Park Lake, Sunninghill, as soon as it got into the water. Such were its exhaustion and terror.

This sport-torture is infamous, and every anti-vivisectionist is bound by logic and common sense to denounce it. I don't know whether I am Dr. Berdoe's "obscure clergyman in an obscure parish"; but, if so, I would ask him not to trouble about my *obscurity*, but to give heed to my facts.

I am, Sir, yours truly,

Wokingham, Dec. 1.

J. STRATTON.

OPERATIONS AT THE CANCER HOSPITAL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I quite admit that Dr. Herbert Snow has the best of the argument if it is a fact that the Cancer Hospital, founded by Marsden, is a general hospital. I confess I did not look up the report, but I have repeatedly seen appeals in the public Press, and to the public it was never, so far as I can remember, held out as a general hospital. The two cases that I mentioned could not by any possibility be classed as cancerous, and it is a revelation that the sequelæ of a neglected miscarriage should be treated at this hospital, as that could not possibly come under the class of "cancer, tumour, or allied disease."

Having lived in this neighbourhood for nearly twenty years I am not ignorant of the ways of this special hospital, and I have, I confess, frequently taken advantage of its lax methods to send a patient for operation who had nothing cancerous the matter. To this extent the hospital has been a boon, but, on the other hand, the out-patient department has treated cases of syphilitic ulcer and other similar diseases in persons who could quite well pay the small charge of a general practitioner. It is to the credit of the Cancer Hospital that it is free, and therefore does not compete with outside practitioners.

Dr. Snow's remarks about the Brompton Hospital are founded on ignorance. The Brompton Hospital is, as it always represented, viz., for consumption and diseases of the chest, and therefore it is quite legitimate in treating heart disease, although to my knowledge it also treats cases of dyspepsia. If we are to have special hospitals, and a great majority of the profession think both the profession and the public would be much better without them, they should stick to their speciality, and decline to treat others.

I am Sir, yours truly,

J. HAMILTON, M.D.

6, Sydney Street, Chelsea, S.W.

Dec. 11th, 1899.

Pharmacy in the Isle of Man.

THE Manx Legislature has passed a Pharmacy Act analogous to the Acts of England and Ireland. The new departure is remarkable in one respect, i.e., that it forbids unqualified assistants to compound even in association with medical practitioners. Every person so employed must either possess a recognised pharmaceutical qualification or a certificate of apprenticeship to an apothecary or a chemist.

Obituary.

MR. EDWARD HAMILTON, OF DUBLIN.

WE report with great regret the death, on the 7th inst., of this well known and much respected member of the surgical profession in Ireland, at his residence in Stephen's Green, Dublin. At his death he was surgeon to Steven's Hospital and surgeon to the Lord Lieutenant and the Viceregal Court, and held many other positions of emolument and dignity. He was born in 1824, the son of Mr. William Cope Hamilton, who was well known to the profession a few years afterwards as medical attendant on the cholera hospital in Dublin. Mr. Edward Hamilton graduated in Dublin University as B.A. in 1845, and took his degree in medicine in the following year. His studies were pursued chiefly in the School of Physic, and in Dun's and Mercer's Hospitals, and, in succession, he took the Letters Testimonial of the College of Surgeons in 1846, its Fellowship in 1852, and the M.D. of his University in 1860. Finally he became President of his College in 1875, and again in 1892, and again in 1893, thus achieving the very unusual honour of a thrice repeated Presidency. He was elected as the Professor of Surgery in the College in 1884. He also occupied the Presidency of the Irish Medical Association and of the Dublin Branch of the British Medical Association. The public and the profession in Dublin had experience for nearly half-a-century of Mr. Hamilton's qualities, his capacity as a practitioner and as a teacher, and his character as a man, and we believe we can say with truth that no gentleman was more universally respected and esteemed than he was by his professional colleagues and his fellow citizens. He was a most conscientious and careful medical adviser, an upright citizen, and a kindly and genial friend, and has left behind him "troops of friends" to mourn his loss. His College has not been slow to record its deep regret for his departure, for its Council adopted unanimously on Thursday last a resolution of profound sympathy with his family and, out of respect for his memory, adjourned forthwith without transacting business.

Literature.

NEALE'S MEDICAL DIGEST. (a)

SINCE 1877, when the New Sydenham Society published Dr. Neale's great work, we have kept the "Medical Digest" on our study table as the most trustworthy book we possess. There is an idea among those not familiar with the book that it is simply an index of the principal British medical journals for the past fifty years. But this does not do anything like justice to the author; besides being an index for fifty and two years, it affords a means of ready information regarding such discoveries, new doctrines, and different methods of treatment in each department of medical science as are likely to be of interest to the practitioner. Its pages mark the steady progress of scientific medicine for over half a century.

Should the practitioner desire to know the therapeutics of any disease as practised to-day or in the past, a reference to the proper section and every shade of medical thought on the subject is displayed to him. To the medical practitioner who has been wise enough to bind his medical periodicals the book is invaluable; it directs him to the very page where the information sought is to be obtained. For the many who do not keep their medical journals the "Medical Digest" possesses the great value of an exhaustive year-book in which no medical subject is overlooked, no treatment unrecorded, no unforeseen result unnoticed. Its 250,000 references give the pith of the British medical journals tabulated with the utmost care; easy of reference, rich in information, and always trustworthy.

To review such a work is a pleasure, and it is even

(a) "The Medical Digest; or, Busy Practitioner's Vade-Mecum to the Principal Contributions to Medical Science during the last Fifty Years." By Richard Neale. M.D. Lond. Third Edition. With an Appendix including the years 1891 to March, 1899. London: Ledger Smith and Co. 1899.

more so to see that the medical profession appreciate Dr. Neale's indefatigable industry and great intellectual ability in his herculean task of classifying, arranging, and editing his "Medical Digest."

CHEYNE AND BURGHARD'S SURGICAL TREATMENT. (a)

THE first volume of this work to be issued in six parts, has been in circulation for some months. It embraces the treatment of general surgical diseases, including inflammation, suppuration, ulceration, gangrene, wounds and their complications, infective diseases, tumours and the administration of anæsthetics.

Our acquaintance with the previous writings of Mr. W. Watson Cheyne on surgical subjects has led us to anticipate a high degree of merit in the volume before us, and having given it a careful perusal we can confidently state that our expectations have been fully realised. It will, we think, be freely acknowledged that a work of this class has been badly wanted for some time, and especially by the younger practitioners whose necessarily limited experience has in many instances rendered it particularly difficult for them to select appropriate treatment out of the long and often bewildering methods recommended in many of the standard text-books. The book is well written, clear and concise, and the rules for treatment recommended are fully in accord with the present state of our surgical knowledge. We congratulate the authors upon the high degree of excellence reached in this, the first volume of the work, and we look forward to the pleasure to the parts which are to follow.

TWENTIETH CENTURY PRACTICE. (b)

THE present splendid instalment of the "Twentieth Century Practice" contains ten articles by a corresponding number of contributors:—"Lobar Pneumonia," by Andrew H. Smith, of New York; "Cerebro-spinal Meningitis," by Professor A. Netter, of Paris; "Dysentery," by Professor A. A. de Azevedo Sodré, of Rio de Janeiro; "Yaws," by H. A. Alford Nicholls, of Dominica; "Inflammation," by Professor Ernst Ziegler, of Freiburg; "Erysipelas," by Otto G. T. Kiliani, of New York; "Simple Continued Fever," by Professor Landon B. Edwards, of Richmond (Va.); "Relapsing Fever," by Professor Leo Popoff, of St. Petersburg; "Typhoid Fever (Etiology and General Pathology)," by John S. Thacker, of New York; and "Typhoid Fever (Symptomatology and Treatment)," by John Winters Brannan, of New York.

The contents of this excellent volume are well qualified to maintain the high reputation of its predecessors. The first article—that on "Lobar Pneumonia," by Dr. Andrew H. Smith of New York—occupies 139 pages. It deals most thoroughly with its important subject, both clinically and therapeutically. The writers clinical acumen is peculiarly well illustrated on page 23. "In pneumonia it is often difficult to auscultate the posterior portion of the chest. To turn the patient so as to bring the affected side uppermost, will frequently cause extreme respiratory distress; and with a weak heart it is not wise to raise him into a sitting posture. To meet this difficulty, I have devised a stethoscope that, by pressing down the mattress with the left hand, can be slipped under the patient on the fingers of the right. The cup of the stethoscope is flat and shallow, in shape like the cover of a pill box; and the rubber tubes instead of coming off from the top, come off from the side at points but little removed from each other. The thickness of the cup is about half an inch. With this instrument the auscultatory signs can be obtained with scarcely any disturbance of the patient." We most sincerely congratulate Dr. Smith on this ingenious and

philanthropic device, which we hope soon to find adopted by skilled physicians throughout the world.

With regard to pathology, after recognition of the function of the pneumococcus, the writer recognises "three types of cases: sthenic, asthenic, and obstructive." And later on we are told that "In addition to the foregoing types there may be differences in the clinical features of the disease depending upon mixed infections. Other organisms may be present with the pneumococcus lanceolatus, such as the pneumococcus of Friedländer, Pfeiffer's influenza bacillus, the Klebs-Loeffler bacillus, the typhoid bacillus, the staphylococcus pyogenes, and the streptococcus. One or more of these acting with the diplococcus proper to pneumonia may modify more or less the clinical picture." Surely of the making of microbes there is no end!

Dr. Netter's excellent article on "Cerebro-spinal Meningitis" gives special prominence to the diagnostic importance of Kernig's sign. He also emphasises the connection which exists between cerebro-spinal meningitis and pneumonia. In the bacteriological section he pursues this point by indicating that relations—probably important, but not hitherto well defined—exist between the pneumococcus and the diplococcus intracellularis meningitidis of Weichselbaum.

Professor Sodré believes in the amœbic origin of dysentery. He places 4 per cent. of hepatic abscesses complicating dysentery in the middle lobe of the liver. We would like to know where the middle lobe of the liver is?

Yaws—*granuloma tropicum*—here receives the fullest recognition as an independent disease. The persistent way in which this malady has been confounded with syphilis is, of course, noticed by the writer, Dr. Nicholls. The diseases often co-exist. "In those cases of yaws in which chronic, intractable, and destructive ulcerations came on, the explanation lies in the fact that there is a complication with tubercle or syphilis." "The theory advanced by Jonathan Hutchinson that yaws may be a syphiloid disease produced by the long influence of race and locality is disproved at once by the fact that syphilis in all its typical forms exists now, and has existed for many generations among the races most subject to the ravages of yaws. Syphilis is the same disease among them now as it was then; time, race, and locality not having altered any of its manifestations."

The appearance of Professor Ziegler's excellent article on Inflammation in the middle of this volume (pp. 355-402) would appear to be, from the æsthetic standpoint, an "incident." We need not criticise it; it is worthy of its author.

Dr. Kiliani contributes a very thoroughly prepared article on Erysipelas. A short article on "Simple Continued Fever," by Dr. Edwards, is followed by a very elaborate one on "Relapsing Fever," by Dr. Leo Popoff, Professor at the Imperial Military Academy of St. Petersburg. As this fever was the great "*famine fever*" of Ireland, which swept that island after each failure of the potato crop, we are obliged to the Irish physicians for the earliest accounts of it. Dr. Popoff makes some very curious blunders in the historical portion of his carefully-prepared thesis, which we would recommend him to correct in any future reprint.

Typhoid fever is very fully and satisfactorily treated in the closing essays of this important volume. Space will not permit us to discuss in detail the vast number of questions which arise in connection with this great subject. Nor, indeed, is it necessary or desirable that we should under any circumstances make the attempt. We refer our readers to the volume before us, with the assurance that they will not be disappointed.

Medical News.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of the Medical Sickness Annuity and Life Assurance Society was held at 429, Strand, London, W.C., on 24th ult. There were present the Chairman, Dr.

(a) "A Manual of Surgical Treatment." By W. Watson Cheyne, F.R.C.S., F.R.S., and F. F. Burghard, Burghard, M.D., M.S., Lond F.R.C.S. Part I. Price 10s. 6d. (London: Longmans, Green & Co., 1899.)

(b) "Twentieth Century Practice. An International Encyclopedia of Modern Medical Science." By leading authorities of Europe and America. Edited by Thomas L. Stedman, M.D., New York City. In twenty volumes. Volume XVI. Infectious Diseases. London: Sampson Low, Marston & Co., Limited. 1899.

Havilland Hall, Dr. J. B. Ball, Mr. J. Brindley James, Mr. Wm. Thomas, Dr. M. Greenwood, Mr. William J. Stephens, Mr. F. S. Edwards, Dr. F. J. Allan, Dr. J. W. Hunt, Dr. J. Pickett, Dr. Alfred S. Gubb, Mr. Edward Bartlett, and Dr. Walter Smith. The Committee examined the accounts, and found that the sickness experienced by the Society during the autumn had been so much under the expected amount that the extra claim account of the earlier part of the year was more than covered, and the record of 1899 would probably show an appreciable increase in the financial strength of the Society. During the fifteen years of its operations and even in the worst time of the influenza epidemic, the growth of the Society's reserves has been uninterrupted. The Committee were able to report every year a substantial addition to the funds, which now amount to over £130,000. Prospectuses and all particulars on application to Mr. F. Addiscott, Secretary Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

The Apothecaries' Hall and the Royal College of Physicians of Ireland.

We are requested to publish the following minute of proceedings of the Board of Directors of the Hall:—At a special meeting of the Apothecaries' Hall on 8th December, 1899, it was proposed by Dr. A. Curran, seconded by Dr. Evans, and passed unanimously:—That the observations with reference to this body made by Dr. Atthill at the General Medical Council in London be considered most unprofessional, totally uncalled for, and highly discreditable to the representative of the R.C.P. Ireland.

Uniformity of Preliminary Examinations.

A CORRESPONDENT of the *Edinburgh Evening Dispatch* writes:—"It would be interesting to know how Sir William Turner reconciles his strong advocacy of the raising of the standard of the preliminary examination in medicine with the fact that the Edinburgh University is at present evading the principal rule of the General Medical Council for maintaining a fair standard. The rule we refer to is that which insists that all the subjects of this examination shall be passed at the same time. The Edinburgh University, on the other hand, allows candidates to pass the examination at two sittings which, of course, makes it very much easier to pass. The University even allows a candidate who failed in other similar examinations in one or two subjects to go up for simply the subjects in which he has previously failed, and, on passing them, gives him a certificate that he has passed his preliminary examination. This anomalous state of matters should be put a stop to at once, as the status of Edinburgh medical degrees is not likely to be improved by trying to attract men and consequently fees by the offer of an easier preliminary examination than is to be had elsewhere."

London Cows and Tuberculosis.

By order of the Public Health Committee of the London County Council, a veterinary examination of all the cows in London cowsheds, with a view to the discovery of tuberculous disease, has recently been carried out. The result of the examination is now reported by the committee. In all, 5,144 cows were inspected, and of these 4,464 were found to be free from disease or abnormalities of the udder. Of the remaining 680 cows, seven were found to have tuberculous disease of the udder, whilst another five were regarded as suspicious. Of the seven cows, five have been sold or slaughtered, and the owners of the other two have undertaken not to use their milk. Of the five suspected cows, the milk from three has been sent to Dr. Klein for examination, and the remaining two have been already disposed of. The milk of two of the three has been found to contain tubercle bacilli. One of these cows has been sent to the butcher, and the other it was proposed to send to the market, whence it was to be expected it would be conveyed to the butcher. Of the rest, 241 cows were found to be suffering from acute mastitis, or affected with chronic induration of the udder, and these cases, the veterinary surgeon thinks, require periodical inspection, as the characteristics of minute deep-seated tuberculous lesions may possibly escape detection. Having regard to the importance of these facts, and with a view to the

protection of the public, the committee intend to ask the Council for the necessary funds for a quarterly veterinary inspection of all the cows in the London cowsheds, and for submitting 100 samples of milk from various parts of London to Dr. Klein for bacteriological examination. The Committee, however, recognise that the examination of cows in London cowsheds would be absolutely futile to prevent the sale of tuberculous milk so long as milk from cows outside the county, which have been subjected to no inspection, is allowed to be sold in London and mixed with milk produced in London. If the result of the bacteriological examination of the 100 samples of London milk showed that a large number were tuberculous, the case for legislation would be strengthened, and the public would be warned of the danger to which they were subjected.

Housing the Poor.

IN the *Leisure Hour* for December, a writer who has worked among the poor for twenty-five years, asserts that not less than 900,000 persons are living in overcrowded tenements in London, and of that vast number about 300,000 are huddled together in single-room tenements. It is no uncommon thing to find from five to eight persons occupying a single room, and careful inquiry appears to have proved that close upon 40,000 unfortunate creatures are living five persons in one room. As might be expected, the effect upon the physical and moral welfare of human beings, herded together under such unnatural, unwholesome, and immoral conditions, presents one of the most pathetic and ghastly aspects of this sombre and formidable problem. With remorseless precision the death-rate increases with density of population, and in such crowded areas amounts to double that prevailing over the whole of the metropolis. When one remembers the importance of bodily health to the labouring classes it is impossible to withhold compassion from men and women compelled to live under conditions which starve and exhaust all staminal strength. Apart from considerations of humanity, the slow but sure impairing of the industrial efficiency of so many thousands of our workers is profoundly to be deplored. If the physical consequences are so serious, what must be the effect of all this herding of human beings on their moral nature? Imagine the brutal frankness, the coarse familiarity, the shameless indelicacy which must obtain where all natural reticences and decencies of domestic life are rendered physically impossible. Every finer sensibility is blunted, and habits of thought and feeling contracted which gangrene the soul.

Glanders in Newcastle.

AN outbreak of glanders has broken out among the horses in Newcastle-on-Tyne, and orders have been given to keep the troughs empty for the present, buckets being used instead.

University of London.

THE following is an official list of the candidates who passed the M.B. Examination during October, 1899, alphabetically arranged:—

SECOND DIVISION.

Bonnerjee, Susila Anita	Mills, Herbert Henry
Capper, Harold Selwyn	Murrell, Christine Mary
Clifford, Harold	O'Dowd, John Austin
Collens, Edward Howard	Osborn, Alfred Gelsthorpe
Collinson, Harold	Pocock, Arthur Robert Geo.
Davenport, Edward Charles	Porter, John Fletcher
Evans Thomas	Potter, Bernard Elwell
Everington, Herbert Devas	Reeve, Herbert Midgley
Ferris, William	Reynolds, Bryan Ellis
Fookes, Ernest Faber	Rhodes, James Herbert
Gaff, James	Robertson, James
Gardner, Thomas Hudson	Stewart, Mary Ariel
Gowdey, Annie Chapman	Stewart, Walter Graham
Hall, Edmund Stokes	Strange, Robert Gordon
Harcourt, John Charles	Swift, Eric Wilson Danby
Hartley, Harold	Taylor, Isaac
Heath, Phillip Maynard	Thwaites, Gilbert Bahn
Hirst, Walter Clapham	Turnbull Jane Holland
Hoban, Thomas	Turner, Philip, B.Sc.
Hooper, George Henry Jas.	Unwin, William Howard
Horn, Arthur Edwin, B.Sc.	Van Praagh, Harold John

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

A SAD AND URGENT CASE.

IN reply to the appeal in our last issue, we have received a cheque for £2 from a correspondent who desires its acknowledgment as from H. S., and one for £1 from Dr. Jas. Hamilton, of Chelsea. We think most of our readers must have passed over the appeal without reading it, or we should have received a different response from the thousands who peruse our pages weekly. The case is an exceptionally sad one, and the urgency of the circumstances surrounding it is our excuse for consenting to act as treasurers, and for pressing its claims on the attention of our readers. The appeal will be found in our last week's issue on page 599.

STOCKPORT (M.D.).—We have referred your question to a specialist, who says that in the erythematous type of lupus erythematosus a prolonged trial should be given to calamine lotion and other soothing applications. Collodion suits some cases. Failing these measures multiple scarification may be tried. The method of carrying out that simple surgical proceeding is simple. Hundreds of shallow incisions are made in all directions across the diseased area, bleeding is encouraged for some time, and then styptics are applied. A general anæsthetic is nearly always necessary. The sebaceous form of the disease requires different treatment.

M.R.W.—Chloroform should not be administered to the same subject twice within a week if it can be avoided, because it has been shown that the elimination of the drug is not completely effected within a shorter period. Sudden pallor with marked dilatation of the pupil is a danger warning, especially if associated with shallow, sighing respiration, and a rapid and intermittent pulse. Gasping is a sign that the proportion of chloroform vapour in the inspired air is too high.

K. S. W.—The question as to the Salvation Shelters is an important one from the public health point of view, and it is to be hoped that a speedy settlement of the case will be made by the Legislature. As things stand these semi-charitable, semi-commercial undertakings are allowed to bring together under doubtful sanitary conditions large numbers of the vagrant poor, who are practically outside the control of the local sanitary authorities.

FOREIGNER.—Official documents will shortly be available setting forth the exact position of foreign graduates in relation to medical practice in this country. Your questions cannot be answered off-hand.

NEO-PRACTITIONER.—The practice of publicly announcing one's intention of "setting up in practice" in a particular neighbourhood is regarded as absolutely unethical. There are plenty of other ways of disseminating a knowledge of the fact, *inter alia*, by calling on the local practitioners, a step which will go far to secure for you a courteous if not a cordial reception.

Dr MARRIS. If you will embody your criticisms in a letter we shall be pleased to give them publicity. The matter is not one which we care to deal with editorially.

Meetings of the Societies and Lectures.

WEDNESDAY, DECEMBER 13TH.

HUNTERIAN SOCIETY.—3.30 p.m. Pathological Meeting. Specimens will be shown by Dr. Hingston Fox, Dr. F. J. Smith, Mr. Targett, and other Fellows.

THURSDAY, DECEMBER 14TH.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 p.m. —Patients and Card Specimens. 8.30. Clinical Evening. Mr. G. Keeling: Congenital Subluxation of Lens.—Dr. C. Shaw: Sympathetic Ophthalmitis after Enucleation. Mr. J. Griffith: Case of Sarcoma of the Upper Conjunctival Cul de sac.—Mr. A. H. Thompson: Embolism of the Central Artery of the Retina.—Mr. G. D. Maynard: Nasal Duct Dilator.—Mr. G. Brooksbank James: Changes in the Macula Area consequent upon Injury.

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover Square, W.).—8 p.m. M. Doyen (Paris) will give a Cinematographic demonstration to illustrate his Operative Procedures on the Abdominal and Pelvic Organs.

FRIDAY, DECEMBER 15TH.

EPIDEMIOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—3.30 p.m. Meeting.

Vacancies.

Bootle Hospital for Infectious Diseases.—Resident Medical Superintendent, unmarried. Salary £120 per annum, with board, washing, &c. Applications to the Town Clerk, Bootle.

Dorset County Hospital, Dorchester.—House Surgeon, to reside and board in the hospital, unmarried. Salary £100.

Guest Hospital, Dudley.—Senior Resident Medical Officer. Salary commencing £100 per annum, with board, residence, attendance, and washing.

Harris Parish Council for the Southern Division of Harris.—Medical Officer and Public Vaccinator. Salary £90, other emoluments. Apply to Mr. T. Wilson, Lochmaddy, Clerk.

Kent and Canterbury Hospital, Canterbury.—House Surgeon and an Assistant House Surgeon, unmarried. Salary House Surgeon £90 the first year, with board, &c. Salary Assistant House Surgeon £50, with board &c.

Leeds, Beckett Street Fever Hospital.—Resident Medical Officer. Salary £150 a year, with board, lodging, and washing.

Lewes Dispensary and Infirmary and Victoria Hospital.—Resident Medical Officer. Salary £100 per annum, with furnished apartments, board, coal, gas, and attendance.

Lincoln Lunatic Hospital.—Assistant Medical Officer. Salary £100, with board and washing. Apply to the Medical Superintendent.

Norfolk and Norwich Hospital, Norwich.—House Physician for two years, unmarried. Salary £80 a year, with board, lodging, and washing.

Parish of St. Mary, Islington.—Medical Officer for No. 2 Upper Holloway Central District. Salary £100 per annum, with certain extra fees. Apply to the Clerk, Guardians' Offices, St. John's Road, Upper Holloway.

Pontefract General Dispensary and Infirmary.—Resident Medical Officer. Commencing salary £150 per annum, with furnished rooms, fire, lights, and attendance.

Queen Adelaide's Dispensary, Pollard Row, Bethnal Green, London.—Resident Medical Officer, unmarried. Salary £100 per annum, with furnished apartments, coal, gas, and attendance.

South Devon and East Cornwall Hospital, Plymouth.—House Surgeon. Salary £100, with board and residence.

Wexford Union Medical Officer. Salary £100 per annum, and £15 as Medical Officer of Health, with the usual vaccination and registration fees. Applications to Clerk of Union. (See advt.).

York.—Medical Officer of Health. Salary £400 per annum. Apply to the Town Clerk, Guildhall, York.

Appointments.

BOASE, RICHARD DAVRY, L.R.C.P., M.R.C.S., Medical Officer of Health for the Madron and Ludgvan Urban Districts, Cornwall.

BUTTERFIELD, FRANK, M.D. Lond., Junior House Surgeon to the Blackburn and East Lancashire Infirmary.

EVANS, ARTHUR H., M.D., B.S. Lond., F.R.C.S. Eng., Senior Surgeon to the East Dispensary, Liverpool.

FAIRWEATHER, WM. ERNEST, L.R.C.P. Lond., M.R.C.S., House Surgeon to the Jessop Hospital for Women, Sheffield.

GUNN, ALBERT A., M.B., Ch.B. Edin., Senior House Surgeon to the Blackburn and East Lancashire Infirmary.

HARPER, J. M., M.R.C.S. Eng., Police Surgeon for Bath.

HARRISON, ALFRED JAMES, M.B. Lond., M.R.C.S., L.S.A., has been reappointed Honorary Physician to the Bristol General Hospital.

HELLIER, JOHN B., M.D. Lond., M.R.C.S., Honorary Obstetric Physician to the Leeds General Infirmary.

HIGGINS, ALEXANDER G., M.R.C.S., Assistant House Surgeon at the West Kent General Hospital, Maidstone.

NICHOLSON, H. GILBERT, M.R.C.S., L.S.A., Honorary Medical Officer to Queen Adelaide's Dispensary, Bethnal Green.

PAGE, HERBERT W., M.C. Cantab., Examiner in Surgery in the University of Oxford.

SYMES, JOHN ODERY, M.D., L.R.C.P. Lond., D.P.H., M.R.C.S., Second Assistant Physician to the Bristol General Hospital.

WHITELOCKE, R. H. ANGLIN, M.B., M.C. Edin., F.R.C.S. Eng., Surgeon to the Radcliffe Infirmary, Oxford.

WIGG JAMES, L.R.C.P. Lond., District Medical Officer for Ward 2 of the Parish of St. Pancras.

Births.

BARR.—On December 7th, at Wentworth, Rotherham, the wife of Horace Chas. Barr, M.R.C.S., L.R.C.P., of a daughter.

BROADBENT.—On December 3rd, at 35, Seymour Street, London, the wife of John F. H. Broadbent, M.D. Oxon., of a daughter.

HEYWOOD.—On December 7th, at Woodside, Hitchin, the wife of Fleet-Surgeon Alex. J. Johnson, R.N., M.D., of a son.

MCLEOD.—On December 7th, at 89, Ladbroke Grove, London, W., the wife of C. E. A. Macleod, F.R.C.S., of a son.

TURNER.—On December 5th, at Portland Place, W., the wife of H. G. Turner, M.D., of a son.

Marriages.

CARTWRIGHT GILES.—On December 7th, at St. Mary Abbot's Church, Kensington, Ernest Hy. Cartwright, M.A. Oxon., of Maidstone, to Dorothy, daughter of the late R. W. Giles, Esq., of 60, Nevein Square, London, S.W.

LYON—RUSSELL.—On December 5th, at St. James's, Westminster, John Lyon, M.D., Fleet Surgeon, Royal Navy, to Josephine H. Russell, Claremont Drive, Timperley.

PILCHER—GARDNER.—On December 6th, at Christ Church, Winstead, Colonel J. G. Pilcher, F.R.C.S., Indian Medical Service, retired, to Elizabeth Emma, daughter of George Gardner, of Fellside, Snarebrook, Essex.

STEWART—LIGHT.—On December 5th, at St. Martin-in-the-Fields, London, Charles Howard Stewart, M.R.C.S., L.R.C.P., L.S.A., of Witheredge, North Devon, to Grace, youngest daughter of Jabez, Light, of Kenley Court, Kenley, Surrey.

RECTO-VAGINAL HÆMATOMA FOLLOWING DELIVERY —INCISION AND DRAINAGE— RECOVERY.

By ARTHUR GILES, M.D., B.Sc., F.R.C.S.,
M.R.C.P.,

Assistant Surgeon, Chelsea Hospital for Women; Gynaecologist
to the Tottenham Hospital.

In July, 1899, Dr. Dodwell, of Battersea, sent for me to see a patient with him under the following circumstances. The patient, Mrs. M., æt. 30, was confined of her second child on July 3rd, between two and three in the afternoon. The labour was normal, though a little tardy, the pains not being very strong. The presentation was left occipito-anterior, and the child was born naturally, and without any rupture of the perineum. The patient complained of pain and soreness immediately after delivery, but nothing abnormal was noticed on washing and inspection. Pain increased locally, and started in the abdomen, so that ten or twelve hours after delivery Dr. Dodwell was sent for. He found that the pain, which was of a forcing character, was referred to the rectum and abdomen, and he ordered a sedative, which gave relief. The next morning, on inspecting the vulva, he found the perineum bulging and distended, and diagnosed hæmatoma. After watching it for a few hours, in consultation with his partner, he found that the swelling was increasing, and sent for me with a view to exploration.

On my arrival, at 8 p.m. on July 4th, I found the patient looking rather ill, and complaining of severe pain in the rectum and vulva. On inspection, the perineum was distended nearly to the size of a foetal head, and the skin at the most prominent part was very dark and almost gangrenous. By the vagina the swelling could be felt to extend up in the recto-vaginal septum higher than the finger could reach. The uterine fundus was higher than the normal, and was apparently pushed up by the effusion. It was decided that as the bleeding was evidently going on, and was likely to lead to sloughing and suppuration if left, the hæmatoma required to be at once evacuated, packed, and drained, the bleeding point being secured if possible. The patient was accordingly anaesthetised by Dr. Dodwell, whilst I had the advantage of the assistance of Drs. Macrory and Martin. After the perineum had been carefully cleansed, an incision $2\frac{1}{2}$ inches long was made over the most prominent point, and a large quantity of fresh blood and clots

was evacuated. The opening-up of the recto-vaginal septum extended higher up than the finger could reach, and so a second incision was made in the posterior vaginal wall, and through this incision the hæmatoma could be explored as far as its upper limit. No actual bleeding point could be detected; but it was ascertained that the cellular tissue of the broad ligaments was not involved in the hæmatoma, which was thus limited to the recto-vaginal septum. After all the clots had been evacuated, the cavity was freely syringed out with warm iodine lotion, 1 drachm to the pint, and then packed with strips of double cyanide gauze (John Milne's) some of which were brought out through the upper, and some through the lower, incision.

The after-treatment consisted of plugging with cyanide gauze and douching with creolin. The plugging was discontinued after the seventh day, and the douching a week later. The patient got up about the twelfth day feeling quite well and with the wound well healed. The perineum looked very well. Recovery was uninterruptedly good, except that on the fifth day the patient got up without her doctor's leave and fainted. The temperature never rose to 100 degs.

This case has seemed to me to be worth recording on account of the rarity of the complication, and because this extensive hæmatoma arose without any apparently adequate cause. A hæmatoma of the labium majus complicating delivery is sometimes met with, especially when there has been a very long tedious labour, or when instruments have been required, or when the vulva has been the seat of varicose veins; but a hæmatoma of the recto-vaginal septum is exceedingly rare, and none of the predisposing causes mentioned were present in this case.

The anatomical conditions of this hæmatoma are worth noting; it opened up a space bounded sharply above by the recto-vaginal reflection of the peritoneum, whilst the lateral boundaries corresponded with the lateral margins of the posterior vaginal wall.

The treatment adopted does not call for much comment; in view of the fact that the swelling was steadily increasing in size, and in view of the threatening tendency of the skin to slough and break down, the only possible course was to open, clear out the slots, and pack. The laxity of the connective tissue in this situation, and the absence of any structures that would cause sufficient pressure to arrest the bleeding, would probably have the effect in any case of necessitating incision and packing, and I doubt whether the accepted rule which is given for hæmatoma of the labium, viz., to leave the swelling unopened except in the event of continuance of bleeding or of sloughing, will ever be found applicable in the case of hæmatoma of the recto-vaginal septum. I should say that here the indication will be to incise and pack early. In conclusion, I wish to thank Dr. Dodwell for kindly furnishing me with the notes of this interesting case.

SUPPURATIVE MASTITIS IN THE NEWLY-BORN.

By FRANCIS A. WINDER, B.A., M.B.,
Rathfarnham.

As several instances of abnormal lactation have appeared lately in the MEDICAL PRESS AND CIRCULAR, and Dr. John Knott has given us his valuable hints on the subject, I would like to bring forward the following cases of suppuration occurring in the breasts of children after birth, associated, as it always is, with previous swelling, and what appears to be secretion of milk.

CASE 1.—Female child, aged fourteen days, the mother, a primipara, had a severe and tedious confinement. My notes are as follows:—Transversely narrowed pelvis, ligaments hard and tense, large outlet, but generally contracted laterally. Presentation R.O.A., large head, elongated antero-posteriorly. She had been nearly thirty-six hours in labour. I applied forceps as the waters had all escaped, and the head was firmly fixed, and delivered her safely after a hard and tedious second stage.

About ten days after birth, the nurse noticed that the child's breasts were swelling, and that she could squeeze a thick yellowish-white fluid from them. She told the mother that this was her own milk going through the child, and that it must be squeezed out. Also that it was very commonly seen in first-born children. She vigorously proceeded with her massage, using a copious amount of goose grease, not only to the child's breasts, but also to her entire body and head "to drive the milk down to the breast;" the breasts became inflamed, and the child broke out in a general pustular impetigo. I saw the child first on the fourteenth day and found both breasts enlarged, conical, soft, and resisting to the touch, the left breast was but slightly inflamed, the right acutely, causing great pain, which had kept the child and household awake for several nights. It fluctuated, and I made a radiating incision in the lower quadrant and there gushed out about an ounce or more of the most fetid pus I ever had the misfortune to smell. I ordered hot boracic poultices to be applied to the wound, and put the child on sulphide of calcium in doses of one-tenth grain. The head seemed inclined to break out in impetigo, in fact, whether from the effects of the goose grease or not I cannot say, but the child seemed to have developed a suppurative diathesis. The breast healed up slowly and finally closed without leaving any scar visible.

CASE 2.—S., Female child, aged 14 days. (The mother was attended during her confinement by a midwife, and was almost convalescent when on the tenth day her left breast became acutely inflamed and suppurated freely). When the child was some 12 or 14 days old her right breast became swollen, and there exuded a thick creamy viscid fluid, to all appearances resembling colostrum, but which microscopically was seen to consist almost entirely of large epithelial cells, leucocytes, and a few fatty granules with much cell debris; in spite of active treatment the glands suppurated and had to be incised, after which it quickly resolved. However, no sooner was it well on the way to recovery before the left breast inflamed and went through the same pathological stages, ending in suppuration. The midwife learnedly explained that the reason the child's breast suppurated was that the child sucked the "matter" from her mother's breast and it settled in her own.

CASE 3.—Female, at one month: both breasts enlarged simultaneously, a thick white creamy fluid could be squeezed from them under the influence of hot fomentations. Treatment by gentle rubbing and strapping was adopted with small doses of hyd. c. creta to keep the bowels free. They subsided without

suppuration. This child died some two months afterwards from erysipelas of the vulva.

CASE 4.—Male child, one week old; immediately after birth the child's right breast became swollen and secreted a fluid similar to above cases. The midwife in charge of the case kept squeezing the breast, which filled again almost as soon it was emptied. It then became inflamed and distended with matter, so that when I saw the child first the breast was enormous, and fluctuated easily. In fact, after the child moved or cried the fluid could be seen to "sog," as it were. I immediately made a radiate incision in the lower quadrant, and evacuated almost three ounces of fetid pus. The cavity was thoroughly syringed out with boracic lotion, a drainage tube put in, and pressure applied, with the result that it quickly healed up. The other breast became swollen when the child was about fourteen days old, but did not suppurate.

Remarks.—Anyone who has seen cases of infants secreting milk in the breasts will observe as follows: (1) It occurs in both males and females. (2) It generally occurs very soon after birth. (3) The quantity secreted is very small and tends to disappear spontaneously; it never oozes from the nipple, and it takes some amount of squeezing to cause it to exude, but if it is "drawn" more is secreted to take its place (it is this "drawing" which causes the breasts to inflame. There is always a history of interference, squeezing, rubbing, pressing the breast, &c.). (4) It is frequently an unilateral phenomenon. (5) It is more frequently seen in the first-born of families.

That the fluid is always of the same nature I think there is reason to doubt. The specimen which I examined microscopically was a very bad specimen of milk indeed. Of course in the absence of a definite analysis it would be impossible to decide definitely, but the small quantity of fat in the shape of globules was very noticeable, but there is a general glandular activity after birth, and it is hardly to be wondered at if sometimes the delicate and so far untrained nervous mechanism goes slightly astray (it is now an established fact that female infants sometimes, though rarely, menstruate), so that consequently if the mammary gland exudes a secretion it is more than likely it will take the form of the ordinary secretion of that gland.

As to treatment, "Foment and leave alone." Give a gentle purgative and your "Witches Milk" will disappear very quickly.

SOME NOTES UPON THE TUBERCULIN TEST. (a)

By EDWARD O. OTIS, M.D.,
Boston.

So long as the tuberculin test has still many opponents as well as ardent adherents, all added evidence is of value in arriving at a final estimate of its worth in the diagnosis of early or doubtful tuberculosis. I offer my experience all the more readily from the fact that no contribution upon the subject has, to my knowledge, been presented to this Association. The problem to be solved is a twofold one: First, is the test injurious as now used? and, second, is it trustworthy?

Those who have used it and still continue to use it are quite unanimous in answering these questions in the affirmative, and my experience accords therewith.

I cannot help suspecting that those who consider the test dangerous even in the small dose now used may be prejudiced by the unfortunate results which

(a) American Climatological Association, 1899.

occurred in the early history of tuberculin from the enormous doses then used. We all look back upon that epoch with a shudder. To pass it by with a remark "that its value as a test is not great, as reactions are obtained in several other diseases," as Fowler does, it likewise seems to me unfair and misleading. Further evidence, to be sure, is needed to establish its exact position as a diagnostic method, but enough has already been adduced to prove its success in the majority of cases. Its rival is the X-ray, but that requires an expert and an expensive apparatus, which limits its use to the few. Anyone can use the tuberculin test.

In view of the extremely favourable curative outlook the early case of pulmonary tuberculosis offers from the present methods of treatment, the profession has never been so eager to detect the beginning of the disease as at present, and any aid in accomplishing this should be welcome, limited though it may be. We all recognise the fact that auscultation and percussion and the sputum examination fail to do this in some, we know not how many cases. If we delay until tubercle bacilli are detected in the sputum the favourable opportunities of the first stage may have passed, never to return.

Before an absolute diagnosis has been established one is naturally disinclined, and lacks the requisite authority to institute a vigorous plan of treatment. Certainty of facts renders one resolute and swift in action. Here, then, is a test which is so simple that any one can apply it, and yet in the majority of cases settles the whole question of diagnosis definitely and at once. If we shall in the future be able to determine some more exact method of dosage, discovering some constant ratio between the dose and the individual, we may find the test to be true in every case.

In common with others, I have injected cases of proved pulmonary tuberculosis which did not react, at least in the general reaction, and, on the contrary, it has happened to me to obtain a more or less complete general reaction when I could not feel convinced that any tuberculosis existed. It may be that above a certain dose, maximum to the individual in question, what at least simulates a general reaction occurs in a healthy person, a temporary poisoning by the tuberculin and its toxins; further evidence, however, is necessary to decide this question.

My observations extended over 111 cases, originally undertaken in an ambulatory clinic for the purpose of arriving at a conclusion as to the proportion of cervical adenitis that was tuberculous. While making these investigations I embraced the opportunity to test all the cases which for any reason suggested tuberculosis, as well as several cases of syphilis and a variety of other cases. In the total number of fifty-six cases of cervical adenitis taken without selection there were thirty-three reactions, six slight reactions, and two doubtful ones. Throwing out the slight and doubtful ones, we have 58.8 per cent.; including them, 73.2 per cent., or an average of 66 per cent., which would indicate the proportion of cases of cervical adenitis that were tuberculous, so far as an inference can be drawn from fifty-five cases and dependence can be placed upon the tuberculin test; but of course a larger number of cases and other methods of investigation must corroborate or disprove these deductions.

It seems not unlikely, however, that this is not far from the truth, for Volland makes the proportion 68 per cent., and Dr. F. C. Moore, (a) out of twenty-eight cases of chronic enlargement of the glands, mostly of the neck, which had to be operated upon for various reasons, found that 73 per cent. were

tuberculous. In eight cases of syphilis and one doubtful one there were four reactions. One of these cases was injected for cervical glands, and reacted moderately after five milligrammes and markedly after ten milligrammes. A few days later evidence of secondary syphilis appeared. Another, of chronic enlargement of the metacarpal bones of two fingers of the left hand, which was diagnosed by one surgeon as syphilis and by others as tuberculosis, reacted after 5 milligrammes, still leaving the diagnosis in doubt. There does not appear to be any doubt, then, that a certain proportion of syphilitic cases will react. This fact, however, would rarely interfere with the test in its more useful application, viz., in suspected early tuberculosis. In seven cases of more or less advanced pulmonary tuberculosis containing tubercle bacilli in the sputum, three gave no general reaction after ten or twelve milligrammes, and one none after five milligrammes. Unfortunately, the local conditions after the test were not noted.

Of course, the only deduction that can be drawn from these few cases is that pulmonary tuberculosis, when more or less advanced, will not always give a general reaction from 5, 10, or 12 milligrammes of tuberculin; it is well to remember, however, the fact to which White calls attention, that the general reaction is slight, and the local reaction marked in advanced cases, while in the early cases, where the test is most useful, the reverse is true. In the other general cases the results corroborated the clinical diagnosis in the majority of instances. Whether any reaction occurred without the existence of tuberculosis one can only conjecture, but it is rather surprising that atrophic rhinitis and pharyngitis sicca should give a reaction without other evidence of tuberculosis. In no case did any serious result follow, although in several the general reaction was severe and accompanied with much temporary depression.

The clinic being an ambulatory one, the subjective evidence of the patient, together with the objective symptoms apparent when he presented himself the next day at the clinic, were mainly relied upon to determine whether or not a general reaction had occurred. If from six to twenty-four hours after the injection the patient complained of excessive weakness, sensations of heat and cold, nausea, anorexia, pain in the back and limbs, severe headache, sweating, either sleeplessness or somnolence, epitomised by him as feeling "very sick," "awful bad," or "miserable," and he appeared the next day with coated tongue, rather a rapid, weak pulse, and a general appearance of marked depression, a general reaction was considered to have occurred, even though the temperature at that time was not much, if at all, raised. The cases were generally afebrile at the time of the test.

Objection may be urged as to the accuracy of these tests when the patient could not be constantly under observation, as in a hospital ward; but anyone who has listened to the graphic recital of the reaction cycle and witnessed the evidence of weakness and depression exhibited by the patient would, I am sure, be convinced that a general reaction had occurred. Of course, all reactions were not of the same intensity or duration.

Moreover, since making my first set of tests, a year ago, Dr. R. C. Cabot, in the out-patient department of the Massachusetts General Hospital, has followed a similar plan in tuberculin and other injection tests, and has satisfied himself also that accuracy of results can be attained in an ambulatory clinic. As a matter of convenience, I gave the injection in the arm, generally subcutaneously, and the site of injection

(b) "Diseases of the Lungs," Fowler and Godlee, 1898, p. 398.

(a) *Lancet*, September 17th, 1893, p. 734.

was swollen and painful for a few days. This annoying sequela can generally be avoided by making the injection deep in the muscles. I confined myself to the use of Koch's original tuberculin, previous experience with which had taught me what to expect from certain doses.

The medical man is likely to be misled, I think, if he uses indiscriminately tuberculin of different concentrations, and therefore he can better estimate his results if he has a single preparation of uniform strength. I dilute the Koch tuberculin to a 1 per cent. solution, using either distilled water or a normal salt solution. Unless one makes a fresh solution every day or two, the addition of a few drops of carbolic acid is desirable. With a pipette graduated into tenths and hundredths of a c.c. milligrammes can be easily measured.

As to the dose, there is much diversity of opinion. Some assert that they obtain satisfactory results with very small doses, as Grasset, with two to five tenths of a milligramme for an adult, and Gaffie, one-twentieth of a milligramme for infants. The majority, however, use larger doses, from one-half to ten milligrammes, and occasionally twenty. Prof. A. C. Klebs regards twenty milligrammes as the maximum dose which can be injected safely, but he would not begin the test with this dose. It is not unlikely that this difference of opinion regarding the dose is largely due to the difference in the strength of the preparations used. I have never used over twelve milligrammes of Koch's tuberculin, generally from five to ten milligrammes for an adult, and from $\frac{1}{2}$ to three milligrammes for children.

I would summarise my conclusions as follows, subject to modification by further experience:—

1. The tuberculin test indicates early tuberculosis by a general reaction in the majority of cases before it can be detected by other methods, the X-ray excepted.
2. The dose to accomplish this is from five to ten milligrammes of Koch's tuberculin.
3. No injurious results occur from the use of tuberculin in these doses.
4. Proved tuberculosis in a more or less advanced stage may fail to give a general reaction with doses of ten or twelve milligrammes.
5. Syphilis gives a reaction in an undetermined proportion of cases.
6. A non-tuberculous person may give a general reaction with a dose above the maximum used in the test.
7. The reaction may be delayed from six to twenty-four hours.

And as rules to be observed in making the test:—

1. Always use the same tuberculin and of a standard strength.
2. Use aseptic precautions in giving the injection.
3. Make the injections deeply into the muscles.
4. Keep a two, three, or four hourly chart of the temperature if possible, beginning twenty-four hours before the injection.
5. Allow several days to elapse before repeating the test.
6. In early cases depend upon the general reaction; in later cases, if the general reaction is wanting, carefully look for the local.

The Portland Hospital.

THE medical staff of the Portland Hospital left London on the 12th inst *en route* for South Africa. The staff consists of Mr. Anthony Bowlby, of St. Bartholomew's Hospital (senior surgeon), Mr. Cuthbert Wallace and Mr. Ernest Calverley (surgeons), and Dr. Henry Tooth (physician), the latter being assistant physician at St. Bartholomew's Hospital. The departure was witnessed by a large number of personal friends of the doctors.

The Harbeian Lectures ON THE SURGICAL TREATMENT OF TUBERCULOUS DISEASES.

By W. WATSON (HEYNE, M.B., F.R.C.S., F.R.S.,

Professor of Surgery in King's College, &c.

ABSTRACT OF LECTURE I.

TUBERCULOSIS OF LYMPHATIC GLANDS.

IN choosing the treatment of tuberculous diseases as the subject of these lectures, I propose to deal with a group of affections which interest both the surgeon and the physician, and which forms one of the most common of the more serious diseases which come under the notice of the practitioner. As a surgeon, I of course limit myself to those lesions which are accessible to surgery, and as the various surgical tuberculous lesions are too numerous for consideration in the three lectures which are at my disposal, and as I have already fully discussed on several occasions the subject of tuberculous diseases of bones and joints, I propose to confine my attention to tuberculous gland disease, tuberculous peritonitis, and genito-urinary tuberculosis.

Tuberculous disease is, in the first place, a local affection, and it may be local even though it is situated at a considerable distance from the possible point of entrance of the bacilli into the body. From this primary deposit tubercle bacilli may be disseminated; either in large quantities along with cheesy particles giving rise to an acute general tuberculosis, or to acute tuberculosis of an individual organ; or in small numbers which may or may not settle in other parts. These apparently secondary deposits may, however, not arise from the former one, but may be new lesions originating from them in the same way as the original one did. It is also probable that tubercle bacilli may live in the blood for some time, and unless they meet with circumstances under which they can grow may remain quiescent or die out.

TUBERCULOSIS OF THE LYMPHATIC GLANDS.

IN all the cases of enlarged glands in the neck it is very common to get a history of an acute inflammatory enlargement of the glands in connection with some acute process at the origin of the lymphatic vessels, such as boils, carious teeth, quinsy, eczema capitis, &c., at the commencement of the trouble, and that as this passed off the glands began to subside, but instead of disappearing as would be the case in a healthy subject, they subsequently enlarged and assumed the characters of tuberculous glands. No doubt it might be that tubercle bacilli entered the glands from the mouth or other source of irritation at the same time as the acute inflammation occurred, and that they afterwards grew and led to the tuberculosis of the glands; but in view of the researches mentioned previously and the remarkable absence of tuberculous sores at the point of entrance, even although wounds or abrasions were present; and in view, further, of the very frequent occurrence of tuberculous glands in different members of the same family, I cannot think that this represents the whole truth. When we remember that in the case of joints and other deep-seated lesions the infection must practically always come from the blood, and that in children the bronchial glands are so frequently tuberculous, I cannot but think that in the case of the cervical glands infection often occurs from the blood also, and, in the absence of a primary tuberculous focus, I am inclined to think that in many cases we have to do with a non-specific inflammation of the glands in the first instance, and a subsequent infection of these inflamed glands with tubercle bacilli from the blood stream.

As regards the clinical characters of tuberculous glands, we find great variations in different cases as regards the number and size of the glands affected, the rapidity in the progress of the disease, and the tendency to softening and abscess formation. From the point of

view of treatment we may consider the cases under the following five heads:

1. In some cases the glands remain hard and small, not large enough to produce deformity, and with no marked tendency to softening. Here one usually finds a number of glands of varying size, but for the most part small, hard, movable, and without any matting together. Fresh glands tend to become involved, though slowly, and if there is no intercurrent trouble, either local, such as sore throat, &c., or general, such as measles, chicken pox, influenza, &c., they tend to disappear gradually as the patient grows older. Where, however, intercurrent troubles, such as those mentioned, appear, suppuration may occur in one or more glands, or the whole trouble may take on a more acute course.

2. In a second set of cases the glands enlarge steadily, or it may be by fits and starts, attain a large size, and become very numerous, so that by-and-by the whole side of the neck becomes a mass of enlarged glands and great deformity is produced. This condition is usually bilateral, although it may be more marked on one side than the other, and it may go on for a long time without the occurrence of suppuration, the glands also remaining more or less mobile and discrete. The glandular disease tends to spread to the axilla. The patient frequently has a pasty complexion, feels weak, and the general health is not good. On removing these glands one frequently finds that they have been converted into large masses of cheesy material; in other cases, while some show only a few caseous or calcareous nodules, others appear fleshy on section to the naked eye without any sign of degeneration; under the microscope, however, one finds that the latter are infiltrated with tubercles and tuberculous tissue.

3. A third variety is where the glandular trouble is more acute and more likely to end in suppuration. Here, in the first instance, the disease may be apparently limited to a few glands, which, however, enlarge pretty rapidly. Further, periaadenitis occurs, the glands tending to become more or less matted together and adherent to the tissues around, while fresh glands enlarge. Where we have this state of matters we find that the glands are breaking down, and suppuration will in all probability occur. If left to itself abscess after abscess may form till numerous ulcers are present, often extending round the neck in the submaxillary regions and downwards along the triangles.

4. We may have to deal with tuberculous glands with unopened abscesses. Suppuration in connection with tuberculous glands may be met with under various conditions. Most commonly the state of affairs is that described in No. 3, but in some cases the disease may be much more limited, and only one gland or one or two small glands may break down. Again, we may divide these cases into those where the abscess is still beneath the deep fascia, and those where it has burst through and formed a subcutaneous swelling, often with thin skin over it. Again, in some cases, the gland may be only partially broken down, and a large quantity of cheesy material and diseased glandular tissue is found at the bottom of the cavity when the abscess is opened. On the other hand, the gland may have completely broken down, and we practically have only a bag of pus. The latter condition is seldom found except where the abscess has gone on increasing underneath the fascia, usually beneath the sterno-mastoid muscle. When the abscess comes quickly through the fascia it generally bursts before the gland has been completely destroyed.

5. Lastly, we have to do with cases where abscesses have burst or been opened and where sinuses remain. In some instances these sinuses may be numerous while in others there may be only one or two. In any case the sinus leads down through a hole in the fascia to the remains of the gland, and generally there is a quantity of cheesy and calcareous material and broken-down gland tissue at the bottom. In addition the skin at the orifice of the sinus becomes the seat of a tuberculous ulcer, so that we may have a large sore in that situation with undermined edges.

In discussing the treatment of tuberculous glands I do not propose to enter into detail on the medicinal

treatment, but to indicate the cases which require surgical interference, and to describe the nature of such interference. Medically there is very little to be done actively against this disease. The patient should, of course, be placed under the best hygienic conditions—country or seaside air, cod-liver oil, sunshine, and a nourishing diet. Some surgeons place great reliance on arsenic in the treatment of this and other tuberculous diseases. Buchner was one of the first to advocate the use of arsenic in tuberculosis on the supposition that it led to the development of fibrous tissue around the tuberculous lesions, and so encapsuled them or even brought about their disappearance. However that may be increasing doses of arsenic not uncommonly lead to diminution in the glands, and should be tried except in cases where immediate operation is imperative. Where the glands are showing any tendency to enlarge or become matted together, it is well to fix the head, and this can be readily done by means of a back splint, which takes a purchase around the thorax, with wings coming forward at the upper part and grasping opposite sides of the head above the ears—practically the splint introduced a good many years ago by Mr. Treves. Attention should also be paid to all possible sources of irritation; carious teeth should be removed, enlarged or diseased tonsils should be excised, adenoids should be operated on, eczema of the skin should be seen to, &c.

As regards local applications over the glands—such as mercurial or iodide of potassium ointments, iodine, &c.—they are, in my experience, of little use. Indeed, where the gland is large and superficial and on the point of breaking down, the irritation of the skin over it with iodine may actually precipitate the suppuration instead of preventing it. Attempts have also been made—and I have made a good many myself by injecting materials into the substance of the glands—to arrest the disease, the materials employed being arsenic, undiluted carbolic acid, iodoform, &c., but none of these have led to any good result, and I cannot recommend them.

With regard to these expectant methods of treatment, it is of great importance to remember that they must not be carried too far, and it is of especial importance not to send the patient so far away that he cannot be kept under observation. One is very apt to allow the patients to go off to the country for an indefinite time, and then find when they come back that suppuration has taken place, and that operation is imperative; the operation then required will probably be more extensive, certainly it will be more difficult and less certain as regards its results, than if it had been done earlier. Where there is any doubt about the case, and especially where one sees the patient for the first time, it is better to watch the case for a time rather than to send the patient away at once.

The operative procedures adopted in these cases are two-fold, namely, either excision or scraping. If excision is adopted its aim is not only to get rid of the actually enlarged glands, but to remove the disease, if possible, completely, so as to avoid recurrence. To do this it is clear that not only should the large glands be taken away, but also the smaller ones in the vicinity which are likewise infected, and the operation to be effectual must be pretty extensive even in comparatively limited cases. The sort of operation which I recommend and am in the habit of practising will be presently described. Scraping, on the other hand, only affects an individual gland or glands which are breaking down, and leaves any others which may be infected behind. These may subside and not give any more trouble, or, on the other hand, especially in the third form above mentioned, they may rapidly enlarge, and fresh scraping may be necessary. This method has its uses in certain cases, as will be presently pointed out, but must rank second in importance and in choice to complete excision.

As a matter of curiosity I have looked out the last 100 cases of tuberculous glands in the neck on which I have operated, with the view of seeing the sort of treatment adopted and the results. Of these 100 cases 30 had unopened abscesses and 18 had sinuses. In some cases scraping and excision were performed in different situations at the same time. The following are the results:

"In 84 cases excision was employed in the manner to

be presently described. (In 4 of these sinuses in the neighbourhood were scraped). In some both sides were operated either on the same day or after a week's interval; 19 of these had abscesses, and 10 had sinuses.

In 12 of these cases other glands in the neighbourhood subsequently enlarged and required further operation. For example, where the anterior triangle had been cleared out glands subsequently enlarged in the sub-maxillary region or on the other side or in the posterior triangle. In none did recurrence take place in the area operated upon.

"In 20 cases scraping was done either because sinuses were present or because there was a single large abscess. In 11 of these unopened abscesses were present, and in 9 sinuses. In 9 recurrence took place *in situ* and further operation was necessary."

Let us next consider the treatment to be adopted in each of the five classes of cases above referred to.

1. These cases may well be watched for a time, treated with arsenic, country air, good hygienic conditions and so forth, and unless the disease becomes active, most usually as the result of some intercurrent affection, there is as a rule no need for any surgical interference. There is no marked deformity in these cases; there is not as a rule much tendency to suppurate, and probably no great danger of dissemination of the disease. As long therefore as the glands remain quiescent these cases may be left alone in so far as active intervention is concerned.

2. The second class of cases, where there is marked enlargement of glands amounting to deformity, and where the glands are numerous and spreading, generally requires operation. A trial of the arsenic treatment may be given, but if it fails operation had better be resorted to. It is not advisable to wait too long in these cases, for the tendency is to progressive infection of the glands, and country air and other expectant means have but little influence on them. As has already been said, in many cases these swellings are simply composed of a mass of caseous material, and while they may not break down the disease has a great tendency to spread down the neck into the thorax and axilla, and to prove a distinct source of danger to the body generally. The only operative procedure possible here is excision; scraping is quite out of the question. The excision, to be of use, must be especially free, and if it is found that any glands beyond the area of operation have escaped they should be subsequently removed.

3. In this group the matting together of the glands as the result of peri-adenitis shows that active inflammatory processes are going on in them; and while they sometimes subside after careful treatment, their progress must be especially closely watched, and, if no improvement follows, operative interference should be carried out before a definite abscess has formed. In these cases some surgeons adopt scraping, others free excision, and I have no hesitation in expressing my very decided preference for the latter course, and that for the following reasons: In the first place, we seldom have only one gland enlarged, while the scraping only affects the individual gland penetrated by the instrument. It is, of course, possible to push the instrument on into other glands, but the result is not very satisfactory, and the smaller glands, which are also infected, are left untouched. Besides, even as regards the glands which are scraped out, it is often difficult, unless they are very much broken down, to clear them out completely, and thus tuberculous material is apt to be left behind which rapidly grows and infects the wound, and thus recurrence very often takes place. It often happens also that the smaller glands enlarge, and a mass quickly forms as large or larger than the original one, and it is probable that the irritation of the scraping increases the inflammation and leads to this enlargement. Further, in a certain number of cases acute general tuberculosis has followed such scraping.

The results of excision in these cases are, as a rule, highly satisfactory, provided that the operation is so extensive as to include the fat and smaller glands in the neighbourhood, and that none of the operation is done by scraping. Some surgeons when the glands are adherent to the internal jugular vein, as they often

are, remove as much as they can with the knife and scrape the part adherent to the vein; but, as I shall state presently, there is no objection to removing the vein along with the adherent gland, no harm whatever resulting from this procedure. I have seldom seen recurrence after these operations, and this is the experience of others, and I have no doubt that in many instances the patients have been saved from a grave risk. It is also very important in all cases to look for and remove a possible primary focus, such as enlarged tonsils, carious teeth, mastoid disease, &c., at the time that excision of the glands is carried out.

4. Suppurating glands. The conditions under which one meets with suppuration in the glands are various, and we may arbitrarily divide them into three groups.

(a) The abscess in the gland has burst through the fascia, but only forms a comparatively limited swelling under the skin. In these cases I advocate complete excision of glands, abscess, &c., in the manner to be presently described, an oval piece of skin being taken away over the abscess. In these cases it is usually necessary also to remove the jugular vein. Care should be taken as far as possible to avoid puncturing the abscess, although in many cases, if large it is very apt to burst, and pus escapes over the wound: even when this takes place it is very remarkable that I have never noticed tuberculous infection of the wound. I have, of course, always washed the pus away immediately, but even doing that, if we judge from the result when a cancerous gland bursts, it is surprising that, in some cases at any rate, the wound does not become tuberculous.

(b) The abscess in the gland has burst through the fascia, and formed a large swelling under the skin with marked thinning of the skin over it. Under these circumstances the removal of the whole of the thin skin, which would be necessary in complete excision, would leave a gap which it is difficult to close, and the scar of which would be apt to stretch afterwards; hence, I prefer in these cases to open the abscess in the first instance, and then later on (in three or four weeks), when the skin has recovered and only a sinus is left, to carry out complete excision. In some cases it is well to scrape out the gland and abscess in the first instance instead of merely opening it, and it may be that this will suffice for a cure, but if fresh swelling appears excision should be performed as soon as the skin has recovered.

(c) An abscess is present which has not yet burst through the fascia. Here one may in many cases wait and allow the abscess to increase till it is probable that the gland has become completely broken down, and then open and scrape out the abscess, inject iodoform and glycerine, and stitch up the wound again. A very small incision behind the sterno-mastoid frequently suffices in these cases, and the resulting scar is practically invisible. Cases, however, in which this result can be obtained are not very common and sometimes a sinus remains, and if it does will not heal, and if fresh glandular enlargement occurs excision should be performed.

5. Enlarged glands with sinuses. Here also excision is the best treatment, unless the sinuses are so numerous that the operation is not practicable. The operation is no doubt somewhat more difficult, but if it be carried out in the systematic manner to be presently described, I have never failed to complete it. Where the sinuses are too numerous for excision, thorough scraping and the subsequent application of undiluted carbolic acid is the best treatment.

Excision of tuberculous glands is an extremely satisfactory operation if carried out sufficiently widely. If the enlarged glands alone are removed, recurrence is very apt to take place, and this is more likely to happen if suppuration occurs in the wound. Under the latter circumstances the glands which are infected but not excised tend to enlarge and undergo suppuration.

I have already said—and I cannot emphasize the point too strongly—that in operations on tuberculous glands one must not be content with shelling out the infected glands, but must remove the whole of the glandular area, whether the glands are visibly affected or not. To shell out the enlarged glands is only to remove the most affected of the glands leaving behind numerous others which are also affected but not markedly en-

larged. It does not, of course, necessarily follow that these glands left behind will enlarge; but they are more especially likely to do so if the operation has been an extensive one accompanied by much tearing of the tissues, and therefore with increased lymphatic flow, or accompanied by suppuration or even a less degree of inflammation. Under those circumstances the glands swell up and the tuberculous disease makes progress in them and generally forms fresh masses. And it must be borne in mind that a second operation in the same region is very much more difficult than the first on account of the cicatricial tissue distorting the relations of the parts. Hence, where glands are removed for tuberculous disease, one must map out and remove all the fat-containing small glands in that particular lymphatic area in addition to the enlarged ones.

The situation where one most commonly has to operate on tuberculous glands is in the anterior triangle of the neck, especially towards the upper part, and there one must remove not only the whole of the fat and fascia present in the anterior triangle of the neck, leaving the vessels, nerves, and other structures thoroughly clean, but if one is to avoid recurrence one must also thoroughly clean out all the tissues underneath the sterno-mastoid, so that the muscles on which the sterno-mastoid rests are completely bared. This cleaning-out process must extend backwards into the posterior triangle, and if glands are enlarged there one can very often, by working from the front, clear out even the greater part of the posterior triangle. In any case it is essential in removing glands from the anterior triangle, whether they be tuberculous or whether they be malignant, to remove all the material around the vessels, whether infected or not and all the fat and glands underneath the sterno-mastoid. Especially with regard to the latter, the removal must extend quite up to the mastoid process, because very often glands enlarge about the region of the transverse process of the atlas, and the material there must also be taken away.

Clinical Records.

WESTMINSTER HOSPITAL.

Cases of Amenorrhœa treated with a New Salt of Manganese.

Under the care of Dr. MURRELL.

E. G., *Æt.* 25, a nursemaid, was admitted November 9th, 1899, for anæmia and amenorrhœa. She stated that her illness commenced seven years ago, when she noticed that she was very pale and was losing strength. She improved somewhat when taking iron pills, but has suffered from three or four attacks of anæmia every year since. She was well fed, had plenty of out-door exercise, and was not overworked. For a fortnight before admission she had been much more anæmic than usual, and found it impossible to continue her work. Her menstrual history had been uniformly unsatisfactory, and it was not unusual for her to go from three to five months without seeing anything. There was no leucorrhœa; she was not pregnant, and she was not constipated. Her blood was examined by Dr. Lazarus Barlow, who found that it was of fair colour, but appeared to be thinner than normal. The red corpuscles were 4,520,000 per cmm. and of normal shape and appearance, but pale. The colourless corpuscles were 7,500 per cmm. consisting chiefly of finely granular oxyphile polynuclear cells and lymphocytes. There was, therefore, no oligocythæmia, and the condition was one of uncomplicated oligochromæmia. It was thought that if the patient's menstrual condition could be restored her general health would improve. Good results would in all probability have been obtained from senecio or from binocide of manganese or permanganate of potassium. It was determined, however, to give the manganese in the form of the new soluble salt, the citrate, a specimen of which had been placed at Dr. Murrell's disposal by Messrs. Burroughs, Wellcome and Co. For the first fortnight no active treatment was resorted to, in order that the

possible effect of expectation, rest and change of diet might be eliminated. On November 25th, the patient was ordered five grains of the citrate of manganese three times a day. On December 4th, she commenced menstruating—the first appearance for nine months; the period was very profuse and continued for two days and a half. The patient stated that she felt better and stronger, and a few days later left the hospital.

J. T., *æt.* 19, a nursemaid, was admitted November 7th, also for anæmia and amenorrhœa. Her case was an almost exact counterpart of the previous one. She had been very anæmic for nearly two years, and for eighteen months had been living at home doing nothing. She had never been quite regular, and for seven months the catamenia had been absent. There was a considerable amount of œdema of the lower extremities, but she was not pregnant, and there was no albumin in the urine. There was no leucorrhœa. Red blood corpuscles 3,830,000 per cmm. The colourless blood corpuscles were 3,000 per cmm., chiefly lymphocytes and finely granular oxyphile polynuclear leucocytes. It was a case of oligocythæmia with considerable oligochromæmia. The patient was ordered five grains of dried sulphate of iron in pill three times a day, with a drachm of sulphate of sodium in hot water every morning. This was continued for a fortnight, but although she improved in strength and colour, the menstrual function was not restored. On November 28th, she was ordered five grains of citrate of manganese three times a day, the dose being gradually increased until December 8th, when she was given 15 grains four times a day. On December 13th, she menstruated, the period lasting for two days. Four days later she left the hospital at her own request. Dr. Murrell stated that as far as he was aware these were the first cases of amenorrhœa treated with citrate of manganese. The effect had been prompt, and the soluble citrate seemed to have many advantages over the insoluble binocide, and the caustic permanganate.

Transactions of Societies.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD WEDNESDAY, DECEMBER 6TH, 1899.

The President, Mr. A. G. MILLER, in the Chair.

MR. WALLACE showed a woman *æt.* 44, six months after pylorotomy for carcinoma of the stomach by Kocher's method. She suffered from severe vomiting for twenty-four hours after the operation, when remembering Kocher's advice, Mr. Wallace caused her to lie on her right side, and the vomiting ceased.

MR. STILES showed (1) a child after operation for severe deformity, following burn of the ankle. The foot was much deflected inwards, and in order to rectify this a wedge was cut out of the tibia and fibula. As the skin on the outer aspect of the ankle was redundant a flap was transplanted from it on to the inner side of the foot; (2) a child with extensive ventral hernia following operation for gangrenous appendicitis; (3) an infant aged three months, which was operated on twenty-four hours after the onset of symptoms of intussusception. On opening the abdomen an acutely inflamed appendix was found and removed. There had evidently been a secondary intussusception of the colon, which had become spontaneously reduced. The origin of the appendicitis was not clear, since the child had been exclusively breast-fed. It left the hospital cured on the tenth day. The incision was made in the middle line above the umbilicus; this is always advisable in young children.

DR. A. A. SCOTT SKIRVING showed (1) a patient after removal of a gangrenous appendix, with general peritonitis; and (2) a child after subperiosteal resection of the lower jaw.

MR. WALLACE showed (1) tumour removed in case of pylorotomy; (2) tumour of the pituitary body, which had apparently given rise to no symptoms during life; (3) calcareous nodule from cerebellum; (4) fracture of skull; and (5) calculus in the ureter.

Dr. HARVEY LITTLEJOHN showed (1) dermoid cyst of the ovary; (2) a heart which had undergone extensive calcareous degeneration. The patient was a young girl who died very suddenly; no cardiac lesion had been detected during life.

Dr. A. D. WEBSTER showed an apparatus for the application of hot medicated vapours to mucous surfaces. It consisted essentially of an ordinary atomiser whose body was formed of a large test tube. This was fitted with a cork or rubber adapter so that it was suspended in a flask filled with boiling water.

Dr. GULLAND gave a microscopical demonstration of Cohn's method of staining fat in urinary deposits and other fluids. Films were fixed in 10 per cent. formalin, stained for ten minutes in a solution of Soudan III, washed in 70 per cent. alcohol, and mounted in Farrant. Fat is stained a bright orange; the process is simpler and cheaper than staining with osmic acid.

Dr. C. W. MACGILLIVRAY read a paper on

THE RADICAL CURE OF HERNIA, WITH STATISTICS OF SEVEN YEARS' EXPERIENCE IN THE ROYAL INFIRMARY.

In deciding whether to advise a patient to have a radical cure performed we had to consider his age, the presence or absence of organic disease, his social position, and the nature of the hernia. Operations for hernia might be classed as (1) *imperative*, in cases of strangulation, where a radical cure was secondary, and the operation should be as simple as possible. (2) *Necessary*, as where a truss failed to keep up the rupture. (3) *Advisable*, as in the poorer classes, and those engaged in laborious work. Congenital hernia in children of the lower classes also came under this head. (4) In some cases, as where the rupture was a bar to entering the Services, the operation was one of *convenience*. As regards the danger to life, in the first group the mortality depended entirely on the local condition and the general state of the patient. The radical cure might well add to the risk of the operation. In the last three groups the mortality in young and middle-aged people was practically nil; in older persons the danger was often greater. The ultimate result was influenced by the age of the patient, and, speaking generally, the earlier the operation was done, the better was it. So long as the neck of the sac was thoroughly obliterated there was not much to choose between the different operations; personally, he preferred a modification of Bassini's operation for adults; for children the operation should be as simple as possible. Union by first intention was always to be desired; the only two recurrences of which he was aware were in patients in whom the wounds had healed by granulation. It was most important to keep the patient in bed for at least six weeks; a truss should not be worn afterwards, as it was liable to cause pressure atrophy. It was, of course, difficult to speak as to the permanency of the cure, but the two cases just mentioned were the only ones he knew to have recurred out of a series of 91. Among these cases he had only had two deaths—one from chloroform sickness and one from double pneumonia. Statistics of the varieties of hernia, &c., were given.

The paper was discussed by Messrs. Cathcart, Thomson, Cotterill, Stiles, and the President.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

MEETING HELD FRIDAY, NOVEMBER 10TH, 1899.

The President, Mr. R. L. SWAN, in the Chair.

THE PRESIDENT delivered an address on "Venereal Diseases and their Therapeutics."

Mr. GLASGOW PATTERSON read a paper on the

TREATMENT OF FRACTURED PATELLA BY AN IMPROVED METHOD.

He recommended the use of a strong silver D-shaped wire, which necessitated only a single drilling of the bone, and was sufficiently strong to allow of very early passive motion of the joint being effected without risk

to the injured fragments. This was an important factor in early and complete restoration of the function of the limb.

Mr. HENRY GRAY CROLY was opposed to the risk of opening the knee-joint. He thought ligamentous union just as good. When last in London he had inquired if there had been any deaths from the opening of the joint in fracture of the patella, and found there had been.

Dr. ORMSBY had seen many cases treated by the Dublin method with a short ligamentous band, and frequently, when the patient was afterwards walking about, people could not say which patella was broken. The advantages of bony union did not appear to him so great as those of a short ligamentous band.

Mr. PATTERSON, in reply, said he had never seen death follow the modern method of treatment, which, of course, should be used only in suitable cases. By the open method, bony union and absolute mobility are made certain within a short time. He felt more and more convinced that, with proper precautions, the opening of the joint is the best method.

ON URINARY INFILTRATION.

Mr. H. GRAY CROLY read a paper on urinary infiltration, illustrated by a series of cases which came under his care in his hospital and private practice. Mr. Croly exhibited six beautifully coloured drawings taken from the patients by Dr. Paul Carton. Some were made in the theatre before operation, others at a later period during the healing process, and some when the wounds were healed. Mr. Croly made important reference to the surgical anatomy of the region involved in cases of infiltration of urine, including a description of the attachments of Colles' middle femoral fascia. All the cases were very severe. Only one fatal case occurred in Mr. Croly's list—in that case the patient delayed in seeking admission to hospital until the local and constitutional symptoms were far advanced. Mr. Croly said he had never seen in any surgical work a drawing of urinary infiltration. The drawings were examined with much interest by the President, Fellows, and Members of the Society, and the communication elicited an interesting discussion. In conclusion, Mr. Croly described gangrenous erysipelas of the scrotum as an affection which might be mistaken for infiltration of urine, and differentiated the cases.

Mr. R. B. M'Causland asked if Mr. Croly thought incision of the testicle in these cases would be dangerous? He thought it remarkable that so many patients recover from injuries of this kind.

Dr. E. H. BENNETT had seen a case where a man was "battered" in the belly, and injury to the bladder was supposed to have resulted. A catheter was passed, and bloody urine drawn off, but the patient objected to the passing of the instrument, and afterwards passed water for himself. He lived for nearly two months and died, not with urinary symptoms, but of obstruction to the rectum. At the post-mortem urinary extravasation into the pelvis was found, although there were no external phenomena to indicate this.

Mr. DOYLE had seen extravasation of urine in a boy, four years old, who had fallen out of bed, causing injury to the perineum. He had obtained a satisfactory result by the usual incisions. He did not see how a difficulty could arise in the diagnosis.

Dr. KNOTT said a large majority of strictures occur immediately in front of the triangular ligament, and the great trouble in treatment is that incisions and instruments are generally stopped here by the ligament.

Mr. CROLY replying to Mr. McCausland, said he did not think incision would be dangerous if it did not go through the tunica albuginea. The diagnosis should present no difficulty, except where infiltration occurs behind the triangular ligament, but he had already mentioned a case of urinary extravasation in which the man's scrotum was tapped with a trocar and cannula. The most deceptive cases are those in which abscess of the perineum exists.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD THURSDAY, DECEMBER 7TH, 1899.

The President, Dr. BURGESS, in the Chair.

DR. HALE showed (1) a case of ulcerative syphilide; (2) a case of eczema of neck, face, arms, trunk, and popliteal spaces due to paraffin.

Dr. GEORGE WILKINSON read the notes of a case of "excision of a gangrenous umbilical hernia, with secondary enterorrhaphy." The patient was a stout woman, æt. 49, the subject of umbilical hernia for twenty-six years. When admitted to the Royal Hospital, symptoms of strangulation had been present for about forty hours only. The hernial sac was about 5 inches in diameter. Sac and contents both were gangrenous. The whole was excised. The contents of the sac were 12 inches of transverse colon, and a large mass of omentum. Paul's tubes were fitted to the divided ends of the colon, which were fixed in the wound. Secondary enterorrhaphy was performed six weeks later, by means of Murphy's button. The patient made a good recovery. A jar preparation of the sac and contents were shown.

Mr. DALE JAMES showed the painting of a case of erythema (?) which gained its chief interest from the diversity of opinions as to its origin. The lesions exist on the chest and right arm, the patient being left-handed. Each spot begins as an indefinite rose coloured patch; this increases and develops into a circle, the centre clearing up. In the circumference minute vesicles appear and dry up, then exfoliation of the cuticle takes place. The patient is a single lady, æt. 30, is highly neurotic, and has had this trouble for seven years. It is probably factitious, although this is denied; and control experiments have failed to solve the doubt as to its being so.

A case of "necrosis of the lower jaw" was shown, the patient being Mrs. D., æt. 35, who was admitted as an out-patient at the Royal Hospital on November 5th, 1898. She had been suffering from swelling and pain in the lower jaw for the last three months. On examination a swelling was found below the anterior surface of lower jaw. Fomentations were ordered, but as she did not improve she was admitted November 25th. An incision was made, and pus let out. Subsequently the jaw was scraped, and extensive necrosis was found. As the disease had progressed it was thought advisable to attempt removal of lower jaw as far as the angle on each side, as this appeared to be the limit of the disease. A skin incision not being feasible owing to the septic condition of the tissues the symphysis was divided, and an endeavour made to saw through the bone at the angle. This was done, but on seizing one half of the bone with the lion forceps after a little manipulation the entire half came out. The other half was extracted in a similar manner. There was no hæmorrhage and the patient made a good recovery. Owing to the *periosteum* being left behind, a new jaw is being formed, but, of course, without the articulation. The patient can talk well and chew anything.

Dr. GODFREY CARTER showed a girl, æt. 14, who was totally blind from optic atrophy, and who was suffering from the effects of a cerebral tumour, probably tuberculous in character, and situated in the cerebellum. Mother and sister died of phthisis, but up to three-and-a-half years ago patient had been apparently healthy, though the large size of her head had been commented upon from infancy. Illness set in with severe frontal headache. When this had continued for a week, patient, who was standing at her front door, vomited, and fell down unconscious; there were no convulsions. Consciousness returned in two hours, but she was blind and paralysed in face and all limbs. There was also complete anæsthesia of limbs and left side of face. Sensation returned on second day, but power only after two or three months. Was able to walk in six months. Vertigo was a prominent symptom. No nystagmus. At this time there occurred a second attack, something like the first. Coma lasted one hour, sensation not affected; there was incontinence of urine for three weeks afterwards. She was in bed paralysed as before,

this time for six months, and was only able to walk in a year. From that time improvement has been gradual. She is intelligent and active, but in addition to being blind there is paralysis of left sixth and seventh cranial nerves, and the left side of the body is weaker than the right. Knee-jerks are abolished, and her gait is stumbling and uncertain. The head is large, as from hydrocephalus, and presents a marked rectangular prominence of occiput. There is also some retraction.

France.

PARIS, December 17th, 1899.

HEMIPLEGIA AND HYPNOTISM.

At the Académie des Sciences a member related the case of a woman of 28 of a very nervous temperament, who was seized with a trembling of half of the body and absolute mutism, followed by syncope, after an angry discussion with her husband. When she awakened from her faint the mutism persisted, and the patient presented hemiplegia of the right side. After a few days speech returned, but the paralysis continued more or less. Movement, although limited, was possible in the arm, while the patient complained of numbness and pricking in the leg; the reflexes were intact everywhere except in the sole of her foot. The case was evidently one of hysterical hemiplegia.

The patient was submitted to hypnotism, and the idea was suggested to her that she did not suffer from the sensation of numbness in her limbs, and that she could walk. The woman walked almost immediately and has remained well ever since (two months).

COXALGIA.

M. Schwartz renewed the discussion on the treatment of coxalgia at the Surgical Society. He said that by the conservative treatment many cases of coxalgia were cured, but after a considerable lapse of time. By resection, on the contrary, the cure was rapid, and if the function of the limb was not absolutely perfect, it could be much improved by an appropriate apparatus. As regarded himself, he resected the articulation of the hip for coxalgia ten years ago, and the patient, who was now twenty-five years old, was able to compete in 150 mile match of bicyclists. The shortening of the limb was only a little over an inch.

M. Delorme said that ten years ago he practiced resection of the hip for coxalgia complicated with fistula on two patients, and both died; he had since renounced that radical treatment, but from what he had heard from his colleagues he was inclined to return to it.

M. Félizet thought that when the conservative treatment produced good effects that the fistulæ closed and the fever fell, they were all agreed that there was no hurry about the resection. On the other hand, when the pain and the fever persisted, and the tuberculous infection was making progress, the radical operation should be preferred. It was a mistake to consider resection of the hip as a dangerous operation; his statistics of 200 cases were ample proof of the relative facility of the operation and its successful result. As to the defective method of walking witnessed in some cases it could be easily corrected with an apparatus.

APPENDICITIS AND INTESTINAL OBSTRUCTION.

M. Aviragnet related two cases of perforating appendicitis co-existing with obstruction of the intestine.

The first was that of a woman of forty, who entered the hospital with symptoms of intestinal obstruction, probably due to cancer and meteorism, obstinate constipation, faecal vomiting, &c., were present. At the end of a few days the patient was suddenly seized with violent abdominal pain and succumbed rapidly to collapse. At the autopsy a cancerous tumour was found in the left angle of the colon, and acute peritonitis consecutive to a perforation of the appendix.

The second patient was a woman of forty-nine, who entered the hospital with symptoms like those of sub-acute appendicitis. Signs of intestinal occlusion rapidly set in necessitating laparotomy. On opening the abdomen acute peritonitis due to perforation of the appendix was remarked. Obstruction of the intestine was also observed, and the distension of the intestine was so great that an artificial anus had to be made in order to close the abdomen. The patient succumbed the same evening.

These two cases proved to the speaker's mind that intestinal obstruction and appendicitis represented frequently cause and effect.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, December 16th 1899.

At a recent meeting of the Society for Innere Medizin Hr. V. Leyden related a case of

ACUTE GONOCOCCUS PERITONITIS

with demonstration of a bacteriological condition of general interest. A woman, æt. 29, had been in the 1st Medical Klinik for 14 days. She was much reduced, suffering from high fever and ascites. The diagnosis was difficult, as there were but few points of indication. Two years ago the patient was pregnant, then jaundice came on, and labour was induced artificially by the medical attendant. Later, swelling of the abdomen came on, the condition varied, sometimes becoming better, sometimes worse, without anything giving an opportunity for a diagnosis; urinary trouble of uncertain character was also complained of. The urine showed no albumen. Puncture of the abdomen was made twice, the liver after removal of the ascites was found to be rather indurated, but not enlarged; no tumour was found in the pelvis. The ascitic fluid which was examined but not very carefully, showed a fluid tolerably rich in cells, but nothing abnormal. The temperature, persistently high, rose to 39.6 degs. C., then there was slight diazoreaction in the urine, nothing in the lungs. Then the fever got much worse, with vomiting, and death took place. The autopsy showed the following: the liver contracted, nodular, cirrhotic, strong interstitial hepatitis, the spleen enlarged. Whether the deceased was a drinker was not ascertained. This condition explained the ascites but not the continuous fever, but the condition of the fluid remaining in the abdomen was surprising. It was markedly purulent, the liver and intestines were thickly coated with fibrin, there was therefore acute peritonitis. The question then arose as to the bacteriological cause for the peritonitis, and the bacterium coli was first thought of. The assistant, Dr. Adam, examined and found cells which he declared to be gonococci. The speaker, and also Dr. Michaelis confirmed

this decision. Cultivation on the ascitic soil showed pure cultivation of gonococci and nothing else.

The gonococcus had recently been made responsible for a series of serious affections, whilst formerly its activity had been supposed to be limited to the urinary passages. It had been seen that under certain, but not accurately known, predisposing causes, it could spread itself in the system, and set up serious diseases. Then in 1893 it was found by the speaker as the sole deposit in a case of endocarditis, and this discovery had been later on confirmed. Since then the gonococcus had been diligently searched for; its presence in gonococcal joint inflammation was known. Concerning its presence in acute diffuse peritonitis, there was at present no clearness of view, although gynecologists had pronounced in its favour. Even in the latest works there was no strict proof that it alone could cause diffuse peritonitis. Only Doderlein with two others had found an exudate with gonococci in which the germ was proved to be the cause of the peritonitis; in all these cases, however, proof by culture was wanting. The case before them was the first in which this proof had been produced.

PERITONEAL SEPSIS AND SHOCK.

An address was recently given on this subject before the Gynecological Section of the Naturforscherversammlung in Munich by Hr. Otto Küstner. According to the speaker, some abdominal cases ended fatally suddenly after operation, in which the symptoms did not correspond to the ordinary ones of peritonitis. In extreme cases failure of the heart was the prominent symptom; but he thought that a deleterious action of germs was the most probable cause. Such fatal action of germs under similar conditions had long been known to surgeons, and the speaker thought it probable that germs played the leading part in these unfortunate cases also. As the action of the poison was shown more markedly in its effect on the heart, it was at first sight probable that patients with weak and degenerated hearts, such as were found in myomatous cases, would be especially endangered. Naturally a seriously degenerated heart would fail more quickly under the influence of a serious abdominal operation, narcosis and loss of blood. This ought to be or must be called shock. It was certainly very rare in rapidly and skilfully performed operations, and also certainly degenerated hearts bore narcosis and loss of blood badly. On the other hand, the soundest and most powerful hearts succumbed to the action of poisons such as could be observed in sepsis following abdominal operations.

Further, the observation of the writer showed that the time limits necessary for a fatal termination were very limited. Sometimes the bacterial growths scarcely extended beyond the field of infection. He chose the expression "peritoneal sepsis" rather than that of "septic peritonitis." As in the present case the inflammatory process really stood in the background. If it were wished to characterise the condition more sharply, it might be called "acute peritoneal septic intoxication," as not the infection but the toxicity was the marked feature. He considers the hands of the operator or of his assistant, or some object coming into contact with the wound during the operation to be the cause of the infection, and counsels greater care in sterilisation of every object that will be brought into contact with the wound, and limiting as much as possible all contact with it. He also believes that when the virulence of the

microbes and their numbers are moderate the Mikulicz tampon will be a protection. But if the virulence is great and the numbers are also great it will be of but little service.

At the Medical Society, November 20th, Hr. Virchow showed preparations of

OSTEOMALACIA

from a woman, æt. 34, who had been treated unsuccessfully by removal of both ovaries. The woman was very fat, and at last she died. The uterus was very hypertrophic, the collum long and firm. Mucous membrane of the interior of the uterus much reddened, just as if a result of recent irritation. The pelvis was deformed, the ilium bent outwards; the thorax showed fractures of the ribs on both sides (some of the fractures appeared to have been caused by transport of the body), many bones were completely dissolved, so that nothing remained of their substance, and red marrow was present throughout their whole extent. In the last century these sanguinolent masses would have been put down to scurvy. The other changes were similar to those which, in recent times had been observed in pernicious anæmia. The calvaria had the appearance, and on tapping gave out the sound, of papier maché.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, December 16th, 1899.

SCARLATINAL (ESOPHAGITIS).

At the Medical Club Knöpfelmacher showed a few preparations taken from cases of œsophagitis caused by the scarlatinal virus. He first referred to Eiselsberg's reported cases of œsophageal stenosis where no direct cause could be discovered from the history in the shape of escharotics, irritants, &c., although there was suspicion of the diphtheritic virus in one case. Knöpfelmacher's two cases of œsophagitis ended fatally. The macroscopic specimens when hardened did not show the necrosis so well as under the microscope. This was coagulated in the thickened mucous membrane and was well brought out by Weigert's colouring, as well as the streptococci and other bacilli; none of Löffler's diphtheria bacilli were to be found. Angina necrotica is a typical complication of scarlatina, although it may also be met with as a prodromal condition of the disease. It is also present histologically in some forms of diphtheria, but in this disease as a fibrinous deposit on the mucous membrane with a similar necrotic effect. In the mixed state where diphtheria and scarlet fever are combined Löffler's bacilli will be found, although often overlooked in the search.

INFANTILE PARALYSIS THROUGH DIFFICULT PARTURITION.

Steiner showed an infant, eight weeks old, with paralysis in the right arm which appeared after it was born. The labour had been difficult with breech presentation and manual relief. Closer examination revealed paralysis of the right deltoid and biceps, as well as supinator longus and brachialis internus in a lesser degree, and it may be represented as a type of Erb's paralysis. Atrophy of the paralysed muscles was also present, with reduced faradic and galvanic stimuli, while degenerative reaction and disturbance of the sensibility observed. The sterno-cleido mastoideus is hard and ropy to the touch.

These cases are shrouded in considerable doubt as to whether the paralysis has an intra-uterine origin from cerebral causes, such as porencephalia, atrophy of the posterior cortex, cerebral degeneration, or hæmorrhage, or whether they have been solely produced in the act of parturition. In the latter case it may also be of a cerebral nature caused by injury to the head of the child, or it may be peripheral by injury to some local centre which comes under the category of Erb's paralysis affecting a muscular group supplied by the plexus brachialis where the lesion is located to the fifth and sixth cervical nerve. Budinger has remarked that great elevation and posterior pressure of the affected arm may thus act on Erb's point between the clavicle and first ribs. He admitted that the pressure applied in this position may have been the probable cause in the case exhibited, and may thus be explained by Erb's paralysis with Budinger's assistance, which he presumes may be induced by the presence of a hæmatoma produced by tearing the muscular structure of the sterno-cleido mastoideus which would thus complete the compression on Erb's point.

In the discussion that followed Neurath described a case of his own where the paralysis was of a paraplegic character. The child when born was in a semi-asphyxiated condition, but after a little perseverance was reanimated.

Attention was soon directed to the peripheral paralysis, which was at first viewed with considerable scepticism. What the real cause could be, till occasion arose in a similar case from a post-mortem examination, when hæmorrhage was discovered in the lumbar region of the cord.

Rosenberg was of opinion that pressure by some morbid deposit was the probable cause of the paralysis, and according to his own experience the prognosis was of rather a hopeless character, as atrophy and subluxation soon appeared.

He proposed early operation in such cases to remove all morbid deposit and prevent further deformity in the muscles or joints.

The Operating Theatres.

FRENCH HOSPITAL AND DISPENSARY.

ABDOMINAL HYSTERECTOMY.—Mr. R. O'CALLAGHAN operated on a woman, æt. 50, who had been suffering for some years from an uterine fibroid which, during the last year had been increasing and was weakening her entire system by profuse loss of blood. When admitted her enfeebled condition was such as to necessitate postponement of operative interference for some weeks, but it was undoubtedly a case in which operation was the only hope of saving and prolonging life. After the patient had been anæsthetised an incision about 6 ins. long was made from the umbilicus to just above the pubes, and the tumour easily turned out. The difficulty that was at once apparent was that the bladder presented high up on the tumour necessitating considerable care in stripping it off the uterus. The broad ligaments were tied on each side and divided. An assistant placed his forefinger on the os uteri through the vagina (which had been previously washed out thoroughly with 1 in 1,000 biniodide of mercury), thus giving a guide to the posterior fornix; this was cut

down upon and the uterine arteries tied on both sides, and thus the whole tumour was removed practically without any loss of blood. Dry sponging having been applied to the cavity of the peritoneum the existing gap between the broad ligaments in the serous membrane was brought together by continuous catgut suture, thus shutting off the peritoneal cavity. The abdominal incision was closed in two layers, one with continuous catgut for the peritoneum and the other with silkworm gut, which took up the layers of the parietes and the skin. Mr. O'Callaghan remarked that this was one of the typical cases of fibroid uterus (œdematous myoma) that justified an operation, which at all times he considered to be most serious, not only on account of the mutilation to the woman but because of the mortality of the operation itself, this being in very skilled hands at least 5 per cent. (that is, he said, taking those cases only in which operation was really justifiable, and not those in which nothing is met with beyond a small fibroid or subinvolution of the womb designated by some as fibroid thickening). With regard to the difficulty with the bladder during the operation, he pointed out that owing to the care which was necessary to strip off the viscus from the uterus the operation was prolonged more than he had expected, although it only lasted an hour. The Trendelenburg position, he said, was not employed during the operation, but the bowels were easily kept out of the operative area by means of thin flat sponges, this he considers sufficient in ordinary cases of abdominal hysterectomy. He thought that in a thin walled abdomen, such as in this patient, two layers of suturing was quite sufficient, while in a fat patient it was always wise to use three layers.

It is satisfactory to state that three weeks after the operation the patient was convalescent, and that she left the hospital at the end of the fourth week.

CANCER HOSPITAL.

TRANS-SACRAL EXCISION OF THE RECTUM.—KRASKE'S OPERATION.—Mr. CHARLES RYALL operated on a man, æt. about 50, who was admitted to the hospital suffering from constant passage of blood, and mucus, morning diarrhoea and pain. These symptoms had been present for six months. There was, too, marked emaciation. On examination just within the anus and affecting the posterior wall of the rectum a cancerous growth could be felt extending upwards for a few inches. There was no evidence of secondary deposit elsewhere. The patient was anaesthetised, placed on the left side in a semi-prone position with the thighs well flexed on the abdomen. A median incision was made from the middle of the sacrum to the margin of the anus, the coccyx and the lower two pieces of the sacrum were removed, and the rectum separated from the surrounding soft structures. The peritoneum of Douglas's pouch was then incised, and by ligaturing and severing the meso-rectum, the bowel was brought down so that a healthy portion could be fixed to the upper angle of the wound; the peritoneum was then closed by suturing it to the anterior surface of the upper rectum, and the bowel was divided well above the disease, and all the lower portion, including the anus, removed; the wound was closed partly by buried and partly by superficial sutures. A dressing was applied, and the patient removed to bed. Mr. Ryall remarked that in this case it was impossible to save the

anus owing to the proximity of the growth, and therefore he considered it advisable to give the man a sacral anus, as this was in a better position for the application of a plug. He drew attention to the early opening of the peritoneum during the operation, which facilitates the separation of the bowel above and need not increase the risks if due precaution is taken to prevent infection, this last being best avoided, he said, by not severing the bowel until the peritoneal wound has been closed. The complete closure of the wound is, he thought, of the greatest importance in shortening convalescence. It is necessary to ensure apposition of the deeper as well as of the superficial portions so as to prevent accumulation of any exudation, and this is accomplished by using buried sutures for the deeper part of the wound.

It is satisfactory to state that a fortnight later the patient was up and about, and by means of a sacral plug he was able to have complete command over his motions.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 20, 1899.

VACCINATION IN EXCELSIS.

WE doubt not that the anti-vaccinationist party are always on the look out for well authenticated cases of small-pox epidemics, for the propagation of their teaching almost depends upon these. Without such records it would be impossible for the party in question to exercise their ingenuity in order to show that the outbreak and continuance of the epidemics were entirely independent of vaccination. An epidemic of small-pox no sooner occurs in a town, compelling vaccination and re-vaccination to be resorted to wholesale among the inhabitants, than the anti-party immediately proceed to argue against the facts, and endeavour to prove that small-pox has broken out as the result of insanitation. For a time some of those who listen to their unphilosophical

cal deductions are impressed, but the progress of the epidemic upsets all calculations, with the result that the unvaccinated community—or those who are left of it—quickly display an eagerness to take shelter under the safe protection of vaccination. In this connection, however, we are glad to draw the attention of the anti-vaccinationist party to the facts in connection with the outbreak of small-pox at Puerto Rico when that island was occupied last year by the American troops. In January, 1890, the American authorities found that in two months no fewer than 3,000 cases of the disease had occurred, and an order was therefore issued by the Governor-General that every resident who had not had the disease was to be vaccinated, and that for the future every infant was required to be vaccinated before reaching the age of six months. An interesting detail in regard to this order was the provision made by the American Government for the supply of the necessary vaccine. It was found that vaccine forwarded from the United States lost its virulence on reaching the island, and this necessitated the establishment of a vaccine farm. The farm was conducted upon a most systematic plan. The men engaged in the work were divided into three gangs, each in charge of an acting assistant-surgeon of the army. First, those testing the cattle for tuberculosis; second the vaccinating squad; third, those collecting the virus. By this means, according to Dr George G. Groff, who contributes a paper on the subject to the *New York Medical News*, no trouble was experienced in producing about 15,000 points each day. Each animal furnished on the average 500 points, the maximum being 3,700. The result of this special effort was that in a few months, that is to say, between the end of January and the end of June, no fewer than 790,000 persons were vaccinated; the authorities consequently have now reason to believe that Puerto Rico is protected against small-pox so far as successful vaccination can effect that object. It is interesting to learn that the populace generally accorded a welcome to the vaccinators and that no disturbance of the peace occurred as a result of the vaccination order. Moreover, it is highly important to note that not a single death ensued which could be strictly attributed to the vaccination. Lastly, at the middle of October following the vaccination campaign, the disease was held to have been stamped out of Puerto Rico, inasmuch as not a single case of the disease, at that date, was known either to the military or the civil authorities. These facts, to which attention is here drawn, probably establish a record in the history of vaccination, and they form a striking proof of the value of the civilising influence brought to bear upon this hitherto Spanish settlement by the Government of America. The whole cost of the vaccination campaign amounted to about £6,400, an outlay which, as Dr. Groff says, cannot be regarded as extravagant in view of the fact that the island has been freed from a loathsome and very fatal disease.

LEAD POISONING IN THE POTTERIES.

AN important step has been taken by the Home Office with regard to lead poisoning among workers in pottery manufacture. The magnitude of the evil was established by Government inquiries, especially by those embodied in the Report of Dr. Thorpe and Dr. Oliver. Even now that steps have been taken to stay the mischief the proportion of sufferers from plumbism among the female workers still approaches 50 per cent. There is little need, however, at this stage of matters, to insist upon the disastrous prevalence of industrial lead poisoning, which has always been most conspicuous in the districts where the manufacture of china and earthenware is a staple industry. The widespread nature of the danger and its absolutely preventibility have been urged in the columns of *THE MEDICAL PRESS AND CIRCULAR* for many years past, and it is therefore with peculiar pleasure that we hail the approach, if not the perfect fruition, of a logical preventive policy by the Home Office, with whom rests the ultimate responsibility in such matters. Among the inquiries conducted by that department was a series addressed to the manufacturers themselves, with results that are most hopeful for the future, if we may judge from the tenour of the circular note officially sent to employers. The Home Secretary has announced his conviction that leadless glaze can be substituted in many branches without detriment to the finished products. That conclusion was arrived at in many unofficial circles long ago, and its practical outcome, namely, the prohibition of the use of lead in glazes, has been warmly advocated from time to time in our own columns. The Secretary of State appears not to have had the courage of his convictions so far as to add prohibition to his Special Rules issued last year. It is proposed to extend the system of medical inspection to the whole of the workers in lead processes, the advisability of which advance is abundantly proved by the actual decrease of cases that has followed partial measures extended over the extremely short period of, roughly speaking, some eighteen months. A proposal of the manufacturers is that where the use of lead is permitted it should be only in a "fritted" form, that is to say, fused into a kind of glass, which is applied either as a dry powder or a paste. The point of this recommendation is that cases of poisoning are either extremely rare or altogether absent from the use of a properly fritted glaze. In applying this principle it is necessary to insist upon a certain standard composition, as otherwise safety is not attained. In order to allow manufacturers to acquire the necessary experience it is proposed to allow a period of two years to elapse before any standard is officially imposed. All these propositions are encouraging to those who are interested in the important social question of the prevention of industrial or trade diseases. They show that the earnest attention of the Legislature is being given to the subject, and that there is every prospect of effectual prevention being carried out within a not distant future.

Above all, they serve as a model of official tact in the way in which the views of workers, of scientific men and of employers have been collated and diplomatically consolidated. If a criticism might be allowed it would be to the effect that the total prohibition of the use of lead in pottery would have gone to the root of the evil. So far as we have been enabled to investigate the matter we can find no valid reason to the contrary. Glazes just as effective, as lasting, and as cheap can be made without as with lead. It is apparently to provide for the possibility of there being some process invented in which lead may be indispensable that the departmental policy has been provided with a loophole, the exact size of which time alone will suffice to determine. Meanwhile, we hail with hearty approval the action of the Home Office in dealing with a serious industrial danger, not only on the score of humanity, but also more generally as indicating a desire to grapple with many problems of a similar nature that urgently call for the light of fuller knowledge in order to guide the iron grip of logical prevention.

THE GENERAL MEDICAL COUNCIL AND THE APOTHECARIES' HALL, IRELAND.

NOTWITHSTANDING that the report of the examiners, inspectors, and visitors appointed by the General Medical Council to supervise the examinations conducted by the Irish "Hall" were effusively eulogistic, the Institution has not "escaped whipping." The inspector states that the "final examination will bear comparison as a test of fitness with any of the ordinary pass examinations within the United Kingdom, and the surgical examiners" (appointed by the Council itself) say that "they were satisfied with the method by which the examination was conducted, and with the standard of knowledge required." There is more in the same strain, yet the observations of the Examination Committee of the Council which presents the report are devoted to picking holes in the examinations and giving expression to that manifest partisanship which has prevented its previous utterances from being accepted with the respect and confidence with which they ought to be regarded. The statements made by the Committee have been shown to be, some of them inaccurate, and others biased and unjust, and, therefore, they go for nothing, but a further opportunity was afforded to Sir Dyce Duckworth, who plays the rôle of the wolf to the Hall's lamb, to attack it when the proposal was made that the Apothecaries' Halls of both London and Dublin should be extinguished by taking them into the examinational conjunctions of England and Ireland. This proposition was made for Ireland in 1886 and was energetically supported by the Medical Council even to the extent that the then President, Sir Henry Acland, went to Dublin, to persuade, if possible, the Irish College of Physicians to accede to it. It was also supported by the Irish College of Surgeons, which was willing to have been party to the proposed triune conjunction, and which, when the Irish Physicians refused to listen to reason, entered into a

conjunction with the Hall, which the physicians in vain sought to prevent by a suit in Chancery. In the recent debate the representative of the Irish College of Physicians raised, for the first time, certain technical objections to such a conjunction. 1. That the Irish Hall is under the supervision of the College of Physicians with respect to the inspection of Apothecaries' shops, and the right of appeal of candidates rejected by the Hall. 2. That the College would object to the increment of the fee of its Licentiates, which would necessarily accrue from the addition of a third body to the conjunction. 3. That, to act with strict legality, the Hall could not charge more than 10s. for its licence, and could not dispense with apprenticeship of its candidates as it now does, and that the College of Physicians could not co-operate in any scheme of examination which would not be strictly legal. While we do not dispute the validity of these difficulties, we know that they have little to do with the real block maintained against an Irish tripartite conjunction, for they would all be got rid of with certainty in a few months by a short Medical Acts Amendment Bill, such as has been passed *nem. dis.* for other bodies, if such Bill were endorsed by the Medical Council, the Irish licensing bodies, and the Privy Council and the Irish College of Physicians. The actual and insuperable obstruction to such a reasonable and business-like settlement of a dispute which has occupied the Medical Council for more than forty years is the morbid respectability of the College of Physicians. Following the example of a more ancient but scarcely more dignified body which has its centre of administration at Rome, it has, since medico-educational reform began in 1858, opposed all advancement with the epigrammatic phrase, *non possumus*. Ireland, in the race for medico-educational progress, has had to pull up in face of this obstruction, and, until some means are adopted to bring this College to an appreciation of the fact that the profession cannot afford to stand still to please it, we do not see what can be done to open the *impasse* which it creates and maintains.

Notes on Current Topics.

The Ready Method in Prescribing.

It is not surprising that the dispensing general practitioner and the chemist have become excessively uneasy at the growth of the "tablet" system of medication, to which a correspondent calls doleful attention, but the observer of the progress of events for the past few years must have seen very clearly that the days of universal prescription writing, and the profits arising therefrom, are numbered. The infinite variety of coated pills and compressed medicines which are now at the disposal of the public and the practitioner, the excellence of their therapeutic combinations and, speaking generally, their trustworthiness cannot be questioned; and, moreover, these preparations afford facilities for the administration

in minute doses of the very active alkaloids which the practitioner prudently hesitates to order in a prescription. We recognise, of course, that special cases require special combinations of drugs which the skilled physician can prescribe, and the skilled pharmacist compound, and for such cases, prescribing must always be preserved, but the occasions for such methods are now somewhat exceptional. The dispensing practitioner and the chemist must see that it has become necessary and will be increasingly more so, to accommodate their practice to the new system, and no longer place their sole dependence on the one-and-sixpenny mixture or the shilling box of pills. We can see, of course, how disadvantageous it must be, to make every patient his own prescriber and dispenser, but to a great extent this has been already done, and it will be quite futile to raise a trade cry against it.

The Thermometry of Phthisical Patients.

ONE of the peculiarities of the sanatorium method of dealing with phthisical patients is the practice of taking the temperature in the rectum rather than in the mouth. This is strongly objected to by some, who regard it as a needless indignity inflicted on the patient by a fastidious superintendent. It must be premised that there is no sort of relationship between the rectal temperature and that taken in the usual way, at any rate in disease. The former may be two or three degrees above the latter, or it may be the same, or lower. If that be the case—and the comparative charts show it to be so—we must either have both or, if only one, the rectal temperature. It is amusing to hear it described as an indignity. Nothing is an indignity if it be for the benefit of the patient. Do we hesitate to feed a young lady suffering from gastric ulcer by nutrient enemata under pretext that it might offend her modesty? We throw not, and the physician has to consult, not abstract æsthetic ideas of what is becoming and what is not, but what is to afford him the most trustworthy indications of the condition, for the time being, of his patient.

The Influence of Age on the Incidence of Tuberculosis.

It is a matter of everyday experience that the incidence of tuberculosis in regard to form and course varies according to the age of the subject. Looking at the question from one point of view we see that while, in the vast majority of cases of tuberculosis occurring in very young children, the alimentary tract is the seat of the mischief, the tendency of the disease to attack the lungs increases year by year as age advances. This peculiarity is easily, and probably correctly, explained by the relative liability to infection, which, in infants, is assumed to be greater in respect of their special food, while in adults and older children the air is supposed to be the principal vehicle of infection. If this liability in respect of infants is conceded, it constitutes a crushing indictment of milk as a food, for it is to

this source that the prevalence of intestinal tuberculosis in young infants is attributed. But there is another point of view, for we find that most cases of what is commonly described as surgical tuberculosis, that is to say, tuberculosis of bones and joints, occurs in adolescents, though, to a less extent, it is met with later on in life. Why adolescents should be more prone to this particular form of the disease is a problem which has not yet been solved. Bone and joint tuberculosis is decidedly rare during middle life, but it undergoes a slight recrudescence as age advances. It has been remarked that phthisical patients rarely develop tuberculous disease of the joints and bones and, conversely, persons afflicted with the latter manifestations of the disease are not often phthisical, though they may become so as the result of a generalised infection having for its starting point the disturbed local lesion. There is much in this distribution of special forms of the disease at particular periods of life that calls for further careful observation, though the general principles of treatment are not greatly modified thereby.

Craniectomy for Microcephalus.

THE surgical enthusiasm with which the suggestion was received some years ago of treating microcephalic idiots by means of craniectomy gradually subsided, when subsequent experience of the operation proved that the results were unsatisfactory. Consequently it is now only upon rare occasions that any case of the kind is recorded. The mortality of the procedure has been estimated by Keen at from 15 to 20 per cent., but, despite this fact it cannot be regarded as unjustifiable to operate when the case selected for it appears to be one in which good might result. Authorities are generally agreed that the congenital cases are unsuitable for operation, while in the late and acquired forms of microcephalic idiocy the prospect of achieving some good is more favourable. It is, nevertheless, beyond dispute that very manifest improvement has been obtained in some cases, and in a case recorded by Wilson, of Toronto, in the current number of the *Canadian Journal of Medicine and Surgery*, it would appear that improvement has followed the operation. The child was five years old, and at the time of his admission into the hospital he could only say one word—"mama,"—and this be indiscriminately applied to every person. Moreover, he could not play with his toys, was very restless, and rubbed his head a great deal. His body also was much bent when he walked. The operation was divided into four stages, with intervals of two or three weeks between each, and in the end about four inches of bone in length, by two inches in breadth, were removed from either side of the sagittal suture. The result was that from the first the child became easier to manage; he began to play with his toys, and to learn a great many words and short sentences. It was also noticed that his disposition became milder, and that his restlessness at nights ceased. Furthermore, it

became possible for him to stand erect, and the improvement in his gait was most marked. Upon the whole, then, this case must be classed among the successes, proving that under favourable conditions the operation is both justifiable and expedient.

A Distinction or a Difference?

WHEN an officer dies on the battlefield having been killed by the enemy, officially his death is described as "killed in action." This latter phrase is one with which every one is familiar, and its expressiveness conveys a great deal of meaning. But those who for any reason were called upon to peruse the *Gazette* of December 5th could scarcely fail to have felt surprised at the announcement relating to the late Major Gray, R.A.M.C. The public a short time ago were informed by despatches from headquarters in South Africa that this officer was killed while attending the wounded in the battle at Farquhar's Farm. Despite this fact, however, in the *Gazette* above referred to, while all the other officers mentioned are described as "killed in action," the late Major Gray is announced as "deceased." What does this mean? Are we to understand that the War Office have determined that a medical officer cannot be "killed in action," or that if while attempting to save the lives of wounded soldiers he be killed by an enemy's bullet, officially he is simply an officer who has "deceased?" The distinction may, perhaps, be a small one, but not so small as the little-mindedness which has probably prompted it. There have been occasions on which medical officers have had to fight for the protection of the wounded under their care; but here again, we suppose, had any of the officers been killed, the War Office would have returned them merely as "deceased." What is quite evident is that the bad *régime* introduced and fostered by the Duke of Cambridge, while occupying the post of Commander-in-Chief, of persistently snubbing the Officers of the Medical Department of the Army, still obtains at the War Office, and presumably things will thus remain until the present Commander-in-Chief makes way for someone else. Meanwhile the public wonder why the Army Medical Service is so unpopular with the profession.

Noise and Fresh Air.

A FACETIOUS observer, commenting on the prominence which has been given to fresh air as a prophylactic against many of the diseases to which human beings are liable, recently called attention to the spectacle of the hermetically closed windows along Harley Street in the early morning as evidence of the fact that medical men, even consultants, do not always practise what they preach. Though at first sight the closed windows might be taken to evince a distaste for fresh air during the hours allotted to repose, the truth is that what the sleepers dread is not fresh air but noise. The average citizen, whose nervous organisation has been rendered irritable by life at high pressure, requires quiet if he is to have his allowance of sleep, and this is precisely what cannot be obtained in towns. If we cannot have fresh air

without noise we prefer to shut out both and risk the consequences. Now that an abundance of fresh air has been laid down as the indispensable condition of a healthy existence it may be that the authorities will become more sensitive in regard to avoidable noises. There is ample evidence of the fact that this generation is less disposed to be tolerant in this respect than were their ancestors. Noiseless pavements have taken the place of the roaring granite blocks of former years, and each year adds to the remedies provided by law for dealing with unnecessary noises. Certain it is that no serious progress will be made with the fresh air propaganda until steps have been taken to disassociate it from its concomitant disturbing influence.

The Bankruptcy of the Irish Branch Medical Council.

THE affairs of the branch Council in Ireland have come to such a pass that the aid of the General Medical Council has been invoked. The Irish Council commenced in the year 1899 with a balance against it in the bank of £154—it had to sell £150 worth of stock in the course of the year, and ended with £124 against it. The total expense for fees to the seven members who constituted the Council during the year was £14 14s., and the total number of meetings held was four which leaves £2 2s. for the year's work for each member. It certainly cannot be said that the Branch Council has "wasted the substance" (of the General Council) "in riotous living." So far has the impecuniosity of the Branch Council gone, that one member told the General Council that it was useless to remit any subject to it because it could not meet for want of funds. The cause of this condition of affairs is not far to seek, for it was, in fact, pointed out years ago by Dr. MacNamara, and the result anticipated by him. The fact is that the Irish Branch suffers from two exhausting depletions which no department could survive. First, a large proportion of the Irish students do not qualify in Ireland but, coming as they do from the Queen's Colleges in Belfast, Cork, and Galway which have no sympathy with the Irish licencing bodies, go straight to Glasgow or Edinburgh, where their passing is gazetted, and their registration money absorbed. Secondly, those who do pass in Dublin are frequently the sons of people whose financial possibilities are well-nigh exhausted when the final examination comes, and the evil day of the official registration (which costs £5) comes. Then the new-fledged practitioner has to wait, and generally fixes his hopes upon an assistantcy or some other official employment outside Ireland, and he postpones the payment of his registration fee until he is in a condition to settle down in such avocation. When he does register, his £5 is swept into the treasury, not of the Irish Council, but into that of England. The first of these depletory influences cannot be counteracted by the General Council because it is the reasonable outcome of the excessive cost of the Irish curriculum and examinations which the local teachers alone can remedy. The

second influence it can neutralise. It only needs, if there be legal power to do it, to order that a practitioner qualifying in Ireland shall register in Ireland. The English and Scotch Councils are now "gathering where they did not straw," and it is but just that they should take their hands out of the Irish pocket.

The Medical Aspects of Christmas Fare.

CHRISTMASTIDE, with its host of traditional joys, has for years untold been the signal of a vast food orgie throughout the length and breadth of the United Kingdom. The shops make a brave show of eatables and every household, however humble, lays in its store of things seasonable for the feast. At such a time it may seem perhaps a little unkind to hint that a skeleton hovers near the banqueting table, but a little further inquiry will show that the kindly hand of medical science may bring a certain amount of protective comfort along with that warning. Does over-eating do any great amount of harm at Christmastide? To a great extent that depends upon the eater. That a certain number of gouty and dyspeptic persons may add to their troubles thereby cannot be doubted. Further that delicate and unhealthy children may injure themselves seriously by an excess of rich and rare food stuffs no one can seriously dispute. Fortunately, however, these weaker vessels constitute a small proportion only of the population, and the residue may pretty safely be permitted, if not actively counselled, to "eat, drink, and be merry." It is not the occasional indulgence in excess of food or alcohol that sets up serious mischief in the individual, the damage follows habitual or frequent abuse. If the fashion of Christmas fare were extended so as to cover a couple of months instead of as many days it is certain that the Registrar-General would forthwith be called upon to record a great increase in the mortality of the United Kingdom. Nor does the occasional indulgence in an excess of food injure children so much as might be expected. The real injury is done at an earlier age by feeding babies with patent foods and stuffs other than milk. After the first two years of infancy the healthy child becomes curiously tolerant of changes in amount and nature of food. At the same time the visit of the family physician may be here and there required to set right some trifling ailment due to our national observance of a great feast day.

The Fighting Qualities of Jam.

The humble "pot of jam" as a feature of campaigns has sprung into remarkable prominence within recent times, and immense consignments of jam, we understand, have been forwarded to the Cape for consumption by the troops. Jam may be described as a humble luxury, nevertheless it is one which is held in high esteem. Even the school-boy in mid-term who receives a consignment of jam from home has reason to feel its influence from the number of friendships that he forms as long as the stock holds out. Again, jam has

certainly a moral influence which it imparts. For example, by adding variety to a meal, which from the monotony of the food provided might be dulness itself, it infuses cheerfulness and, no doubt, more or less contentment, among those who partake of it. Not much, perhaps, on the other hand, can be said of its nutritive qualities. As a nutrient, *per se*, the value of jam cannot be much. In all probability, the sugar which it contains proves to be its most serviceable constituent in this regard. Indirectly, however, the desire for eating larger quantities of bread which the liberal use of jam creates makes up for any deficiencies in nourishment which it may happen to possess.

Cork County Council and Lunatic Accommodation.

WE have, on more than one occasion, referred to the very crowded state of the Cork District Asylum, and the necessity which existed for further accommodation. The Asylum Board has been active for some months in the matter, and has almost come to a point of decision where the defects should be made up. Their idea is to have two Auxiliary Second Class Institutions for Imbeciles at separate and distant locations in the county, so as to meet the convenience of districts. Unfortunately, this decision will not be arrived at without some little local recrimination, and a deputation waited on the County Council a few days ago to urge the particular claims of the Schull Workhouse as an auxiliary lunatic asylum for imbeciles. From the newspaper reports it does not appear clear that any special advantage can accrue from agreeing to the prayer of the petitioners, one of whom gave as his argument that as £20,000 to £30,000 were to be expended, he saw no reason why his division of the county should not get a portion of it. With all respect to the reverend gentleman's view, actuated no doubt by motives of local interest, which, in their way, are very commendable, we fail to see how they can have much sway in view of the crucial question, what is best for the efficiency and economy of the whole asylum administration of the county, and what is best in the interest of the lunatics themselves?

Popular Errors Regarding Insanity.

THE course of Armistead Lectures which are in course of delivery at Dundee will conclude with a lecture on "Popular Errors Regarding Insanity," by Sir John Batty Tuke. The Dundee *Advertiser* gives an interesting review of the lecturer's professional biography, and suggests two important doubts to be solved, with the hope that Sir John will attempt to solve them in the final lecture referred to. The first is: Can he give a definition of sane and insane? The second: Can he throw light on the question of responsibility of insanity from alcoholic excess? These are two very interesting questions, and our contemporary has given Sir John a rather hard nut to crack. It may not be his purpose to touch on these subjects, but they are matters of great interest, and the latter especially is one of practical import-

ance, the solution of which we are still far from having reached.

The Loss of Some Portion of the Intestine and its Influence upon Health.

NATURE has provided man with about twenty-five feet of intestines, from which one may assume that for her requirements this is the least amount which she could do with. Since, however, surgeons have invaded the abdomen and performed a complexity of operations from time to time, upon the organs contained therein, Nature has taught us a good many things. Formerly it was believed that the sacrifice of a few inches only of the intestinal tract was likely to be harmful to the processes of nutrition. But the result of operations upon a large scale in this regard have undeniably proved the contrary. In the *Montreal Medical Journal* for the current month, Shepherd publishes a table of twelve cases showing the recoveries which have taken place in patients who have lost portions of the intestine varying from 10 ft. to 30 ins. The maximum instance was that of a boy, a patient of Ruggi, in which the intestine was removed for multiple strictures, and his health was stated to be fair at the end of two years. Nearly 8 ft. of intestine (92 ins.), again, were removed by Shepherd in the course of an operation for tumour of the mesentery, and the patient was still in good health at the end of seven months. Also in a case of Kocher's nearly 7 ft. (82 ins.) were removed in consequence of a railway injury, and the patient was still in fair health at the end of six months. It is interesting, however, to note that in this latter case a marked tendency to diarrhoea supervened after the operation, and in other instances this condition has been noticed. Thus some amount of careful dieting has been found necessary under the circumstances in question. The whole subject is one of considerable interest, especially when taken in conjunction with the recorded cases of excision of the whole stomach, in which life has been preserved.

Leicester Guardians.

THE Leicester Board of Guardians have at last come within the strong grasp of the law, and they will pass the festive Christmas beneath the chilling shadow of a writ of attachment from the Court of the Queen's Bench. Whether the law will allow these rebellious subjects to retain their personal liberty during the next few weeks remains to be seen, but they have long since forfeited any right to expect further leniency from the long-suffering hand of the law. The writ of mandamus from the Queen's Bench calling upon them to carry out the Vaccination Act was evaded by the shallow artifice of appointing as Vaccination Officer a man of notoriously anti-vaccinationist views. Out of nineteen candidates for the post the Guardians chose an ex-journalist who had refused to have one of his own children vaccinated, and who could not by any reasonable probability be expected to administer the Act efficiently. Before the Queen's Bench affidavits were produced from nineteen of the Guardians apologising for their conduct and

saying that although they may have acted mistakenly they acted in accordance with their views of public duty in fulfilment of pledges given at the time of their election. It may be remarked that if they give illegal pledges to their constituents they can hardly be called upon to fulfil them, besides, resignation is open to them. The judge said the object of the Court was not to send the Leicester Guardians to prison, but to make them feel that the law was too strong for them, and that they must obey the orders of the Court. The present position is that the Guardians have to apply within the next five sittings of the Court for the discharge of the writ by showing that they have appointed a proper vaccination officer or else they will go to prison.

The New Vaccination Law and its Cost.

THE St Pancras Board of Guardians have been discussing the cost of the new Vaccination Act and comparing the outlay with that of the Act which it succeeded. In the first place they have found that the sum of £420 more was spent upon vaccination during the twelve months ending September last than was the case in the previous year. On the other hand all that there was to set against this increase was a saving of £82 in rent of vaccination stations and other expenses incidental to the old system. It was pointed out that the official who reaped the most advantage was the public vaccinator, for while his share of the work had only increased by five cases, his emoluments were £320 more in comparison with the previous record. This increase was partly due to the higher fee paid for vaccination in consideration of the domiciliary visit; and partly to the new regulation under which the public vaccinator receives a shilling for every child not vaccinated before the end of the fourth month after birth. It is evident that the ratepayers throughout the country will have some grounds of complaint upon this score. But they have to thank the anti-vaccinationist party for the increased expenditure of public money in this regard. The Legislature passed the Act of last year merely in response to the agitation of the busybodies both within Parliament and outside of it, and the result is that while medical men are profiting by an increase in their fees, the ratepayers have to find the money.

The University of Birmingham and the General Medical Council.

A POINT of considerable importance to the profession is raised in a correspondence recently published in the *Birmingham Daily Post* in respect of the representation of the future University of Birmingham on the General Medical Council. Dr. Kirby, addressing himself to the Council of Mason College, calls attention to the anomaly of the representative of a corporative body being elected by such a restricted body instead of by the general body of graduates, and he ventures to suggest that the selection should be made by the latter, and that the draft Bill should be modified accordingly. The reply of the Council partakes too much of the *non possumus* character to be satisfac-

tory, though one paragraph holds out the olive branch in that it states that as the Bill cannot be proceeded with until after the sealing of the charter, it cannot well come on before Easter, so that "there is plenty of time further to consider the question." We trust the members of the Birmingham and District General Medical Practitioners' Union will take advantage of the opportunity to bring influence to bear on those who are responsible for the draft Bill, and, failing success in their efforts, we may look to the other medical organisations to insure that this point is duly brought forward when the Bill comes up for discussion in Parliament. We do not despair of the reform of existing licensing bodies in respect of their representation on the General Medical Council, but it is essential, as far as possible, to prevent any exaggeration of the anomaly by an addition to the number of corporate representatives on the Council elected on the "pocket borough" principle. The matter is one which interests not only the medical inhabitants of Birmingham, because the principle involved affects the profession as a whole.

A Conflict of Medical Evidence.

It is a well-recognised maxim that medical experts should take every possible precaution to fall into line in respect of the *facts* of the case which they have been called upon to examine, though, of course, a difference of opinion as to the inferences to be drawn from the appearances is perfectly admissible. Any conflict of evidence on material points infallibly tends to bring medical evidence into discredit, the more so as it is difficult to conceive of any material divergence of views on points of actual observation. One expert may, it is true, observe details which another has overlooked, but this does not involve any contradiction of terms. At the trial of a person for murder at Birmingham last week, a deplorable conflict of medical evidence elicited animadversions on the part of the judge, and led to the acquittal of the accused. Dr. Parry, on the one hand, stated that a certain punctured wound of the lobe of the left ear had penetrated to a depth of three-eighths of an inch, giving rise to cerebral hæmorrhage sufficient to cause death. Dr. Holdsworth, the police surgeon, on the other hand, stated that the punctured wound only extended to the skin behind the ear, and had not penetrated the skull. Now the point at issue is one which ought not to admit of any difference of opinion. It is difficult to conceive of such a divergence except as the result of separate examination, but we have no means of knowing whether the examination was made separately or conjointly. The perforation may well have been overlooked by one witness, but a positive statement by the other carries with it greater weight. A few moments' previous conversation between the medical witnesses would probably have sufficed to dissipate the obscurity, or still better, an examination in common. The proper course, if circumstances had allowed of it, would have been to refer the question to an independent expert, who could not have failed to establish the actual condition of things.

The Army Medical Department.

LIEUTENANT-COLONEL W. JOHNSTON has been appointed to be Assistant Director of the Army Medical Department. The selection invites the attention of the profession chiefly because he succeeds Lieutenant-Colonel Gubbins, who has been drafted off to South Africa, and because he is a retired officer who has been employed in recruiting. The lamentably derelict state of the Army Medical Service may be judged from the fact that not a man can be found in England fit to fill this important position without going to the reserve for him. How extreme must be the pressure to provide for the exigencies of the Service may be judged from the fact that an official who is busy in performing engrossing functions in the Irish Civil Services has been requisitioned to join because he happens to be a militia reservist, and that a civil practitioner has been appointed to the charge of troops who is engaged in "covering" the unqualified assistants in a shop in Dublin.

A Gold Disease.

AN American medical journal mentions that two medical men in Johannesburg have discovered a new disease to which they have given the name "*Rhinitis specifica acuta*." It is said to be caused by a diplococcus identical with the pneumococcus, but much more virulent. In thirty-six fatal cases much pus was found in the sinuses of the brain, and pneumonia was a frequent complication. The workers in the gold mines are the chief sufferers.

Tuberculosis and Dairies.

AN important step has been taken by the London County Council with regard to the elimination of tuberculous milk from the area within their jurisdiction. It is to be hoped that this departure marks the beginning of a state of things that will one day cut off one of the great sources of a pestilential disease among the inhabitants of the United Kingdom. The Council have decided to submit a hundred samples of milk taken at random to an eminent bacteriologist for examination for the specific bacillus. By a recent order of the Local Government Board, 1899, the Council have the right to examine cows, byres, and milk, and to prevent the sale of tuberculous milk. The Council, however, once more realised the imperfect nature of the existing legislation upon the subject. This recognition was embodied in the adoption of an amendment which sanctioned the sending of a circular communication to districts supplying London with milk asking what they were prepared to do by way of co-operation. Some of the statistics of the cows in London are interesting and suggestive. Of the total number of 5,144, the udders of 4,464 were found free from disease or abnormality; 7 had tuberculous disease of the udder, and 5 were suspected of the same; 82 had acute mastitis; 165 chronic induration, and 214 atrophy of the gland. Without powers of compulsory slaughter, and without a sound and loyal co-operation between town and country, it will be impossible to carry out any really effectual

scheme of prevention in our large towns. There can be no reasonable doubt that tuberculous milk is largely concerned in the causation of infantile tuberculosis.

Latest Arrangements for the International Medical Congress, Paris, 1900.

DR. CHAUFFARD, the secretary-general of the Congress, has issued a notice saying that the Paris Executive has been considering the important question of housing foreign members who attend the Congress. It has been arranged that the Rector of the Academy of Paris will place at the disposal of the General Committee 800 beds in the various Lycées at Paris during the Congress week, and it is hoped that an additional 200 may be obtained, making a total of one thousand. The price of each bed is fixed at five francs fifty centimes a day, to comprise bed, attendance, and the eight o'clock "petit déjeuner." The beds, of course, are in dormitories, and not in separate rooms, but the Committee think they may be of service to those who come as bachelors and with only scantily lined purses. Nothing is yet decided about the distribution of these beds, nor is the Committee prepared to receive the names of those who wish to take advantage of them, but due notice will doubtless be given. The chief Parisian excursion agents are now ready to receive applications for rooms from intending visitors who do not patronise Messrs. Cook and Son, the agents recommended by the English Committee. The names of the French agencies are (1) "Voyages Duchemin," 20, Rue de Grammont, Paris; (2) "Voyages Modernes," Rue de l'Echelle, No. 1, Paris; (3) "Voyages Pratiques," 9, Rue de Rome, Paris; (4) "Agence Desroches," 21, Rue de Faubourg Montmartre, Paris; (5) "Agence Lubin," 36, Boulevard Haussmann, Paris.

To See Ourselves as Others See Us.

WE cull from the *Evening News* the following bit of wisdom from the judicial Bench:—

In the Bow County Court a domestic servant claimed £50 damages from the Great Eastern Railway for injuries sustained by being knocked down at one of their stations. The doctor's bill came to £3 13s. 6d., the visits being charged at 2s. each. Judge French: Preposterous. A shilling a visit is quite enough for attending a servant girl. I shall only allow a guinea for the doctor's bill, and ten guineas damages for the plaintiff. Counsel for defendant company: We offered £20, but they would not accept it. Judge French: A very generous offer indeed.

We should understand the learned (?) judge's views better if he would tell us whether he recollects having ever given legal advice to a servant girl or anyone else for one shilling or ten times that sum, or whether he thinks of making a scale for the retailing of such very uncalled-for advice from the Bench graduated according to the social position of the client? It is one of the advantages or disadvantages of our system that a County Court Judge, like a curate in the pulpit, may say anything he pleases without being challenged by anyone. Such func-

tionaries are liable to let their tongues run when they think there is no reporter listening.

MR. TIMOTHY HOLMES, M.A. Cantab., F.R.C.S., has been elected to an Honorary Fellowship in his old college, Pembroke, Cambridge.

The *Times* states that Sir William MacCormac and Mr. Treves, whose assistance was invited by the War department, have gone up to Frere near Colenso, with an ambulance party.

PROFESSOR OGSTON, of Aberdeen, who makes it clear that he has not been invited, has intimated his intention of going out at his own expense, to see the medical service of the war and to be of assistance if asked.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

SANATORIA FOR CONSUMPTIVES IN SCOTLAND.

SOME months ago we pointed out the antagonistic positions taken up by supporters of different sanatorial systems of combating tuberculous diseases, especially those of the lungs. *Apropos* of this article, we were the recipients of several protesting letters and communications, all of which came from adherents of one of the parties, all maintaining with no little heat that their opinions on the subject were most catholic, although ending in dogmatic assertions that the only system of the slightest value was that to which, individually, the writers had pinned their narrow faith. Of course, to vary the methods observed at any one sanatorium further than those necessitated by intercurrent conditions occurring in the patients, would present many difficulties in management, where the number treated was large, and the staff small. But an ideal sanatorium would be one in which the number of patients was not excessive, or if great, not beyond the powers of the acting staff to supervise intimately; in which all the patients were not submitted to one single routine system, but treated according to idiosyncrasy, result, and habits.

It is distressing to meet with such strongly rooted ideas as to the absolute possession of curative powers by one single method of treatment in highly educated physicians, so close to the dawn of the twentieth century. They descend to the level of the herbalist or homeopathist who believes that one certain drug in one certain dose is the only infallible remedy for one special symptom, because of some fancied parallelism, or from some fortuitous series of successes following its practical employment. The *Glasgow Medical Journal* lately contained a note about an old medical club at a meeting of which the principles of the fresh air treatment of phthisis were adumbrated years ago to meet only with derision. Dr. Caton's book upon the Grecian temples of Aesculapius shows that their priests acquired very probably much of their success in the treatment of disease (ascribing it, of course, to the action of their deity) from the use of fresh air as the chief factor. The modern method is but a resurrection, nor does it become any of the present plagiarists of ancient unappreciated prophets to dogmatically state that their pet scheme alone is the proper method at a time when the different systems are but in the infantile stage, although savouring of re-incarnation.

Connected with this subject hangs the question of the possible and probable advantage to be gained from the establishment of rural sanatoria in our own country. Several such institutions have already been started. The Victoria Hospital for Consumption in Edinburgh being, we believe the pioneer; Nordrach-Mendip in Somersetshire, on the plateau which reaches back towards the

east from the summit of the Mendip Hills' western escarpment; the Bournemouth sanatorium, the recent small establishment opened to the south of Edinburgh, and many others, testify to the zeal with which this method of treatment is being taken up by the profession and the public. Personally, we have often cast a longing eye on the high bracing, dustless moors which surround Braemar and the higher reaches of the Dee, as theoretically perfect positions for sanatorial treatment, even though the winters there are cold, and the region remote. But the public is not yet educated up to the idea that cold at a bracing altitude at home (whatever its effect at Davos), is less harmful than lesser degrees of cold in more relaxing surroundings, or that cold *per se* is inimical and not favourable to the tubercle bacillus, so long as the actual or possible victim to the bacillus avoids a life spent indoors with a minimum of fresh air and a maximum of artificial heat, with infrequent excursions into the outside cold and seldom respired pure air; followed shortly by return to and existence in an enervating, de-oxygenated, stagnant atmosphere, peopled in fact in contact with a case of phthisis, with numerous germs of infection, and suited precisely to encourage the growth of the bacilli which have already found a corporeal breeding place. But it will probably be long before a sanatorium rises amid the solitary, but as yet untainted, high grounds of Caledonia.

Although many references have from time to time appeared in connection with the erroneous ideas held in the South as to the winter climate of many parts of Scotland, few appreciate the fact that over a wide extent of the Northern Kingdom the climatic conditions in winter are, as a rule, less rigorous than those in all but the furthest south west corner of England. Nor is the reason of this far to seek, for Scotland is a narrow strip of land between the Atlantic and the North Sea; narrower considerably than England, hence is blessed with a less continental and a more equable climate. That of course applies to the areas of land in both countries of corresponding elevation.

Misty, wet, and stormy it may be, but the mist and rain generally come from the warm west, directly from above the warm Gulf Stream. For instance, the mean temperature of Leith in January for forty years, from 1856 to 1895, comes out nearly a degree above that for Greenwich, and the same as that of Lowestoft for the same month. In December Leith also boasts a higher mean temperature than Greenwich. As far north as Aberdeen the means for these two months equal or exceed those of many observed over the midland and south-eastern counties of England. Similarly the entire eastern districts of Scotland are by no means so wet as the usual conception of the country as a whole would indicate. The figures given by the Royal Meteorological Society for the east of Scotland include Braemar, a station 1,114 ft. above sea level, but even with those from this elevated station yield only two inches of rain per annum in excess of the fall in England, south.

Dr. Buchan, in the *Journal* of the Scottish Meteorological Society for 1898, discussing the meteorological conditions of the British Islands says as follows:—"The rainfall of those upland districts of the east of Scotland is also comparatively small. The admirably bracing and hygienic qualities of those regions which have relatively dry climates, and are 700 ft. and upwards above the sea, are everywhere recognised, and it is these qualities which give the upper districts of Deeside, Donside, and Speyside the finest summer climates anywhere to be found in the British Islands."

The papers also by Dr. Buchan in same journal for 1892, discussing the temperature of London for 130 years (1763-1892), and of the north-east of Scotland for 129 years (1764-1892), show that the coldest December and January recorded for the north-east of Scotland, were not so cold as the lowest mean temperatures for these months observed in London during that period.

Again, the Gulf Stream more closely affects Scotland than it does the western shores of England. One winter, seven or eight years ago the Thames was frozen over, while in Scotland summer clothes scarcely required a winter addition.

These facts and many more like them can be adduced in support of the benefits which may accrue from sanatorial methods introduced in the midst of the absolutely undefined breezes coming from off the Scottish mountains and moors. And such should be to the advantage of the new Nordrach-on-Dee, a sanatorium designed to carry out as fully as possible the systems which have met with such success in Germany, named with a paucity of invention, but as an indication of the method to be pursued.

A site has been obtained near Banchory, 18½ miles from Aberdeen, a district richly wooded with pines, on which a sanatorium for from thirty to forty patients is in course of erection, and which, it is hoped, will be ready for opening by May, 1900. Some there are who assert that situation has little or no influence upon the course of the fresh-air treatment of tubercle; but, other things being equal, it is surely but rational to suppose that the purer, more bracing, and drier the air, and the more attractive the surroundings, the greater the chance of benefit, the more rapid the recovery. The venture will be watched with great interest, the result of "guid, shairp, Scotch air" on the vitality of the tubercle bacillus can hardly fail to prove as satisfactory, as it seems to be, upon the character of the Scottish nation as a whole.

THE APOTHECARIES' HALL OF DUBLIN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the last issue of your journal there appears a paragraph from which I learn that the directors of the Apothecaries' Hall of Dublin have passed a resolution pronouncing my conduct at the recent meeting of the General Medical Council to be "most unprofessional, totally uncalled for, and highly discreditable." It seems to me that these gentlemen are quite ignorant of the true state of the case, and I am sure that with your usual fairness you will give me space to state the facts.

I desire, in the first instance, to point out what has been my conduct with reference to the Apothecaries' Hall in the past. Thus, when I was elected a fellow of the College in 1860, if a member of the Apothecaries' Hall of either London or Dublin desired to obtain the licence of the College of Physicians, he had to resign that of the Apothecaries' Hall, and bind him-

self not to engage in the sale of drugs. This I looked on as unfair to certain country practitioners, and, mainly as a result of my action, these rules were repealed, and now a member of the Hall can obtain the licence of the College, and compound medicines if he wishes to do so, the restriction not to do so being confined to "members" and "Fellows" only.

Again, in 1889, when examiners in surgery were given to the Hall, I moved in the College of Physicians that the Apothecaries be permitted to conduct part of the examination about to be carried on by the College in conjunction with the College of Surgeons. These acts of mine show I was not hostile to the Apothecaries' Hall, nor was my opinion as to the advisability of the latter course changed till after the revelations made in the General Medical Council in 1894-5, which ended in the examinations conducted by the Hall in conjunction with College of Surgeons being reported to the Privy Council.

At the recent meeting of the General Medical Council, Mr. Brown brought forward a resolution to the effect that it was desirable that the Apothecaries' Hall of Dublin should be joined with the two Royal Colleges in conducting a qualifying examination, and he called on me to give reasons for the College refusing to do so, and I felt bound to comply.

A point having been made that the Council had pronounced in favour of a similar conjunction with respect to the Apothecaries' Hall of London and the London Colleges of Physicians and of Surgeons, I said that the College of Physicians of Ireland objected to a similar one: 1st, on the ground of the relative positions of the two bodies; that there was no analogy between the Apothecaries' Hall of London and that of Dublin, as was very commonly supposed:—(a) the former by their Act (George III. cap. cxciv.) were empowered to appoint examiners to examine and "ascertain the skill and abilities of such persons in the science and practice of medicine and" their fitness "to act as an apothecary." The only powers granted to the Dublin Hall are contained in the following George III. cap. xxxv.):—

"No person shall open shop or act in the Art and Mystery of an Apothecary until he shall have been examined as to his qualifications and knowledge of the business" by "the Governor, Deputy Governor, and Directors of the Apothecaries' Hall in Dublin." You will observe the London Hall can appoint examiners in medicine not being members of their body. The Dublin Hall cannot legally do so. Moreover, the Dublin Hall was expressly established only for the purpose of having "medicines of the purest quality prepared under the inspection of persons skilled in the Art and Mystery of an Apothecary."

(b) The master and wardens of the London Hall were empowered to inspect apothecaries' shops, while with respect to the Dublin Apothecaries the College of Physicians of Ireland were empowered to do so, and till the establishment of the Pharmaceutical Society of Ireland regularly did so.

(c) There is a right of appeal by candidates rejected by the Dublin Hall to the College of Physicians; a right which has been repeatedly acted on, while no such rights or powers were conferred on the London College of Physicians.

The Apothecaries' Hall of Dublin, is therefore subordinated to the College of Physicians in Ireland in these and other matters, and College deemed that under these circumstances it could not agree to the conjunction.

(2) The College also objected to the increased expense which candidates would be compelled to pay for a Licence very few would desire to hold, and many objected to. There was also with respect to this a legal difficulty. The Apothecaries' Hall charge a fee, I think, of £10, while by their Act they are only permitted to charge a "sum of 10s. and no more"; that sum would not pay the expense of the examination, and if the College consented to a larger sum being charged they would be a party to an illegal act.

3. A further legal question had to be considered by the College, the Apothecaries' Act 40, Geo. III., already

referred to, by which alone the Hall is constituted, the governor and directors are strictly enjoined to require every candidate for their licence to undergo an apprenticeship for the period of seven years. The directors have ceased to require this, and the College of Physicians feel that a serious responsibility would rest on them were they to ignore this evasion of the statute.

These were the reasons put forward when the subject was discussed some ten years ago, and all still hold good. But there are other matters of more recent occurrence which weigh greatly with me. The Apothecaries' Hall of Dublin owes its being, as is stated in the preamble of their Act, to "the existence of frauds and abuses practised (on the public) by the ignorance and unskillfulness of persons pretending to the art of an apothecary to the injury of the fair trader, and the hazard of life," and to the Apothecaries' Company was entrusted the duty of seeing that pure drugs only were sold in Ireland. For many years it discharged its functions efficiently, but it aspired to become a licensing body similar in position to the London one, though it had no right under their Act to such, and from that time not alone have the important functions for which it was established been allowed to sink into abeyance, but it has connived by participating in itself in a scramble for drug contracts in Ireland, which is pronounced by THE MEDICAL PRESS AND CIRCULAR "to be in about as corrupt a state as possible," and to which it adds, "We are obliged to conclude that the Hall has entered the lists, as one of the ruck of drug traders who deal with Boards of Guardians and are willing to adopt their methods. We do not know that we could say worse" (vide Supplement THE MEDICAL PRESS AND CIRCULAR, September 23rd, 1896, p. 21). I read an extract from this article to the Council, and it was this which was in my mind when I said in my place in the General Medical Council that the Hall was not a body with which any of the Medical Corporations having due self-respect ought to combine.

I am, Sir, yours truly,

LOMBE ATTHILL, M.D.

December 16th, 1899.

PRESCRIBING BY THE READY METHOD.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I would like to draw attention to the injury done to the public and to the profession generally by the growing practice of prescribing tablet preparations and proprietary drugs.

We have by our weakmindedness introduced in our midst a very dangerous element, and it is about time we woke up to this important fact. We have been cleverly hoodwinked by tablet makers and patent medicine manufacturers, flattered by their apparent generosity in keeping us supplied with free samples, diaries, pictures &c., have allowed ourselves to drift from prescribing the well tried drugs of the B.P., only to find ourselves the allies of scientific chemists and experimenters. The practitioner of to-day (who does not dispense his own physic) thinks he is showing a great amount of medical knowledge by writing on his prescription *Liq. So. X.Y.Z.*, or tablets do. (A.B.C.) but does he stop to think that by so doing he injures the patient, the chemist, and also himself.

Wherever the fashionable physician goes he finds tablets containing antipyrin, caffeine, sulphonal, thyroïd, &c., &c., taken by patients with as little hesitation as they take their meals.

We have a committee who draw up a Pharmacopœia for our benefit, we study materia medica and pharmacy; we expect our chemists to study the mixing and compounding of drugs with a skill acquired after years of practice, and yet we deliberately insult them by writing prescriptions containing made up mixtures and pocket bottles of tablets, which might be dispensed, if I may use the term, by a grocer, with equal safety; thus we rob the chemist of his profit and livelihood, making the foreigner rich at the expense of our own kith and kin.

Week after week we read of people overdosing themselves with cocaine, sulphonal, &c.: doubtless in all these

cases they have to thank their medical advisers for introducing into their lives a new vice quite as dangerous as alcoholism or the opium habit.

It is time we became alive to these dangers by a closer study of the B. P. We ought to find everything that is needed for our daily practice without having recourse to the tablet system of medication. Every post crowds our consulting room tables with circulars puffing up new remedies. If there be any merit in them, why does it not originate from the proper quarter, the B. P. Committee, or some of our learned Societies?

I have made it my business to discuss this method of modern prescribing with several pharmaceutical chemists, and the general verdict is that the system is ruinous to the interests of the doctor, chemist, or patient, and shows an utter neglect or ignorance of the medical man of his clinical teaching.

On this subject there is food for reflection, and I trust something will be done to prevent the sale of dangerous drugs, which may be picked off the counters of the Stores without even the authority of a medical prescription.

I am Sir, yours truly,

H. A. D.

Obituary.

SIR RICHARD THORNE THORNE.

BUT a few days since Sir Richard Thorne Thorne occupied his accustomed seat as a Crown member of the General Medical Council, and took part, with his usual zest, in the debates. Nothing in his appearance or attitude suggested that he was otherwise than in the best health, yet it is now our sad duty to record his death, after an illness of very brief duration, on Monday last, at the early age of 57.

Thus comes to an end an exceptionally brilliant and successful career. Originally a "Bart's" man, Sir Richard early turned his attention to hygiene and State medicine, and his life has been one long series of valuable services rendered to the State and to science, culminating in his appointment to the post of principal Medical Officer to the Local Government Board, a post which he still occupied at the time of his death, and which he filled with credit to himself and to his department.

There is hardly a point in preventive medicine which at one time or another Sir Richard has not dealt with, and his assiduity was not less remarkable than his singular lucidity and breadth of view. He is especially well known in connection with his work on the use and influence of hospitals for infectious disease, which paved the way to the system now generally adopted throughout the country, but he was also the author of epoch-marking contributions to the study of the prevention of diphtheria, and later of consumption. Innumerable reports from his pen, relating to public health, have appeared in various official compilations, all characterised by the thoroughness and grasp which rendered all his contributions to science at once interesting and instructive.

Sir Richard Thorne was a man of singularly unpretentious and prepossessing manners, and a favourite with all who were privileged to meet him, either in his public or private capacity. He only received his knighthood in 1897, and the news of his death will come as a shock to all who take an interest in sanitary work.

DR. JOHN FREDERICK HODGES.

THE death is announced at a ripe old age of Dr. John Frederick Hodges, Professor of Agriculture and Lecturer on Medical Jurisprudence in Queen's College, Belfast. Educated at Trinity College and the Royal College of Surgeons of Dublin, he became, in 1837, a licentiate of the Faculty of Physicians and Surgeons of Glasgow, and afterwards studied in Germany, where in 1843 he graduated doctor of medicine in the University of Giessen. He then applied himself to the study of analytical and agricultural chemistry; and subsequently filled the offices

of chemist to the Chemico-Agricultural Society of Ulster; analyst to the City of Belfast and to the counties of Antrim, Tyrone, and Donegal; Professor of Chemistry, Royal Belfast College; Examiner, Queen's University, Ireland; and president of the Natural History and Philosophical Society and of the Royal Academy Institute, Belfast. He was the author of a number of works bearing on chemistry, especially in its agricultural bearings, and was for some time the editor of the journal of Chemico-Agricultural Society of Ulster.

DR. ANDREW SPEARING, OF RIVERSIDE.

THE death of Dr. Spearing took place last week at his residence, Riverside, Antrim, at the age of 74. He became a licentiate of the Apothecaries' Hall, Dublin, in 1850; M.D. University of Glasgow, 1851; and a member of the Royal College of Surgeons, England, 1851. In the early days of his professional career he settled down in Antrim, where his practice gradually became extensive, and his relations with all grades and sections of the community were of the most cordial kind. He also held the medical appointments to the Dispensary district and to the Workhouse dispensary at Antrim, and on the death of the late John Taggart, M.D., succeeded him as medical officer to the workhouse.

Literature.

MADDOX ON THE OCULAR MUSCLES. (a)

NO one has done so much to advance our knowledge in this country of the subject of the working and the defects of the ocular muscles than has Dr. Maddox, and for this reason a welcome may be extended to the present volume, not only for the excellent manner in which the author has placed his knowledge before us, but also for the amount of special information which it contains. "The subject," says the author in his preface, is "not without its interest to physicians and neurologists, even when treated from an ophthalmic surgeon's point of view," and there is no doubt that this is correct; "muscle problems" as the author describes them, are now becoming much more frequent in the practice of general physicians than was the case a few years ago, for the simple reason that they are coming to be more generally recognised. Not by any means the least interesting part of the volume before us is the description, occupying several chapters, of the physiology of the ocular motions. This in itself shows the painstaking study which the author has expended upon his subject. Probably, however, the chief attraction of the work will prove to be the observations upon heterophoria. These will well repay perusal, giving as they do an excellent *resumé* of the subject. In short, we think that Dr. Maddox's book is one which ophthalmic surgeons cannot well afford to be without; there is no doubt that it is a valuable addition to ophthalmological literature.

MUIR AND RITCHIE'S BACTERIOLOGY. (b)

THE second edition of this excellent manual will be welcomed by those who are interested in the science of bacteriology. The rapid growth of the subject and the complicated processes needed in its prosecution have carried applied bacteriology more and more to the domain of the expert. At the same time it is necessary for every medical man, whatever his particular bent, to have a general knowledge of the principles, methods and results of the science. The busy practitioner, whether engaged in general or special practice, is every day more and more driven to entrust complicated clinical investigations to laboratory specialists. In

(a) "Tests and Studies of the Ocular Muscles." By Ernest E. Maddox, M.D., F.R.C.S.Ed., Ophthalmic Surgeon to the Royal Victoria Hospital, Bournemouth. Bristol: John Wright and Co.

(b) "Manual of Bacteriology." By R. Muir, M.D., and J. Ritchie, M.D.Ed. Edinburgh and London: Young J. Pentland, 1899.

a case of suspected enteric fever he knows that agglutination of typhoid bacilli in culture is caused by serum from a typhoid patient. The actual test he leaves to the bacteriologist, and all he wants is a telegram announcing the result. All who wish to read a systematic account of bacteriology in its present stage will find what they want in the admirable volume written by Drs. Muir and Ritchie. Clearness is an unailing characteristic of their pages, and in dealing with specific organisms they have in each case commenced with a concise historical summary. The first part of the book contains an account of practical methods, and a full bibliography is appended. There are 120 illustrations, many of them of great beauty and delicacy.

TRAITE DE MEDECINE ET DE THERAPEUTIQUE. (a)

WITHOUT undue delay, considering the scale of the undertaking, we are now in possession of vol. vi. of this majestic compilation. The thousand pages or so which go to make up this portly volume are devoted to diseases of the heart and circulatory system, of the lymphatic system and of the blood, a scope which affords ample material for the writers to whom these sections have been assigned.

The section on the heart and its diseases is from the pen of Dr. Pierre Merklen, and extends to close upon 500 pages, yet an attentive perusal leaves the conviction that the author has not introduced a superfluous paragraph. It is a masterly monograph which exhausts the subject without dragging in unnecessary details. The text is elucidated by a number of carefully selected diagrams illustrating the seat and extent of the auscultatory phenomena to which allusion is made. We are introduced to a new term in connection with the physical examination of the heart, viz., phonendoscopy, by which is to be understood the delimitation of the outlines of organs by combined auscultation and percussion, a method of physical investigation to which attention has been called in this country by Dr. Maguire. In spite of the fact that by its aid the practised observer can easily map out the limits of organs so enlarged or to be in juxtaposition and can even define the position of the cardiac septum, the method, we are told, is not likely to come into general use, on the one hand because it requires considerable and assiduous practice, and on the other because the information to be obtained by simple percussion amply suffices for ordinary clinical purposes. Skiagraphy of the heart is discussed with the remark that it is more interesting than useful, though it may assist us in detecting physiological and pathological variations in the size of that organ in confirming the diagnosis in obscure cases of aneurysm, and possibly in the early recognition of the lesions of arterio-sclerosis.

The chapter on diseases of the arterial system has been contributed by Drs. Roger and Gouget, whose special aptitudes in regard to the subject are fully recognised by those who are *au courant* with the progress of medical science in France. There is not much that is new to be said on this subject, but unless by the designation *arterite noueuse* attention is directed to a rare form of acute arteritis characterised, post-mortem, by the presence of nodular, fusiform thickenings, of a grayish white or yellow colour, varying in size from a pin's head to a millet seed, or, in some instances, by small aneurysmal dilatations which may attain the size of a filbert. The treatment of these various conditions does not offer much scope to the therapist, but the pathological importance and prognostic value of the lesions confer a special interest on their recognition.

The chapter on disease of the aorta in particular, is written by Dr. Boinet, and that on disease of the veins by Drs. Vidal and Bezançon. Dr. Bezançon is also responsible for the chapter on diseases of the lymphatic system. The last named subject is one that is assuming a greater importance than authors in the past have appreciated, and the role of the lymphatic system in the

generalisation of infective diseases is a point to which Dr. Bezançon has devoted special attention.

The remaining chapter on diseases of the blood, written by Dr. Parmentier, is specially worthy of note. During the last few years a vast amount of information has been gleaned concerning the chemical, physical, and bactericidal properties of serums, and the introduction of the serum test has opened up a fresh vista in the recognition of disease. Widal's reaction in typhoid fever is declared to have met with universal acceptance, and we are given the history of the discovery from Pfeiffer's early observations on the action of the comma bacillus under the influence of the serum of an immunised animal, and the discovery now associated with the name of Widal. It is interesting to note, on the one hand, that the characteristic agglutination is also met with in cholera, plague, pneumonia, and tuberculosis, and, on the other, that certain chemical substances are also capable of determining a reaction, similar to, if not identical to, that produced by serum. Under the head of "blood diseases" we get chlorosis and the various forms of anæmia, as well as lymphadæmia and leukæmia, though in all probability the disorganisation of the blood, in the last-named, is rather a symptom of the disease than the disease itself.

We can speak with special commendation of the directions for treatment under the various heads. The remarks are concise but they cover the entire field, and confer a special value on the work as a whole.

FERNIE ON ANIMAL SIMPLES. (a)

THIS is a companion volume to the author's well-known "Herbal Simples," and the least that can be said of it is that it is a most entertaining compilation. Appropriately enough Dr. Fernie introduces his subject by quoting "The Witches" from "Macbeth." This forms the text of his discourse, and very faithfully and fully does he work it out. Those to whom the subject of folklore forms an agreeable pastime will find in Dr. Fernie's pages a wealth of material to their liking. Indeed, almost upon every page one comes across some curious and interesting fact concerning some old-time remedy. Of course, we know nowadays that most of the messes and concoctions which did duty for therapeutic agents in olden times acted more through the mind than through the body. Who for example, would in the present day expect to derive any benefit from taking six dried grasshoppers for an attack of cold, or to have deafness cured by dried finely powdered earwigs mixed with hart's urine, or "difficult breathing," as Pliny says, relieved by an oily decoction of cockroach. But these are only some of the samples of mediæval therapeutics to which Dr. Fernie directs our attention. On the whole the volume is a fascinating one to peruse, and is at the same time a valuable contribution to the literature of the subject.

NEW BOOKS AND NEW EDITIONS.

The following have been received for Review since the publication of our last monthly list:—

BAILLIÈRE, TINDALL AND COX (London).

Heart Disease, with special reference to Prognosis and Treatment. By Sir William Broadbent, Bart., M.D., F.R.C.P. Lond. and John Broadbent, M.A., M.D. Oxon., M.B.C.P. Lond. Third Edition, pp. 420, with coloured and plain illustrations, price 12s. 6d. net.

Rhinoplastic operations, with description of recent improvements in the Indian Method. By D. F. Keegan, M.D., F.R.C.S. Pp. 72, with twenty-one photo-type illustrations, price 5s.

A Synopsis of the British Pharmacopœia, 1898. By H. Wippell Gadd, M.P.S., with Analytical Notes and Standards, by C. G. Moor, M.A. Cantab., F.I.C. Fourth edition, pp. 224, price 1s. net.

Formulaire des Médicaments Nouveaux pour 1900. Par H. Bocquillon-Limousin et Henri Huchard. Price 2s. 6d. net. Dictionnaire des Termes de Médecine. Par H. de Meric, M.R.C.S. Eng. Vol. II, Français-Anglais, p. p. 244. Double column, price 4s.

J. AND A. CHURCHILL (London).

The Pathologists' Note-book, for the Post-mortem Room. By T.

(a) *Traité de Médecine et de Thérapeutique*. Par M.M. Brouardel et A. Gilbert. Tome VI. Paris: J. B. Baillière et Fils. 1899.

King's College Tutorial Classes.

THE success which has attended the special class for intending candidates for the Primary F.R.C.S. has led the staff to organise a class on similar lines for the final examination for the Fellowship as well as for university degrees in surgery. The names of the teachers, Mr. M. Watson Cheyne, A. Carless, G. L. Cheatle, and A. W. Cadman, constitute a sufficient guarantee of the excellence of the course, of which advantage is sure to be taken by those who appreciate the immense advantages which these classes offer to intending candidates.

Isolation Hospital for Dublin.

THE Dublin Corporation has rejected a proposal from the Public Health Committee that temporary arrangements would be made with Cork Street Fever Hospital for receiving infective cases, and it has ordered a further discussion of the matter as soon as a complete return of the hospital accommodation can be prepared. The Boards of Guardians do not seem disposed to co-operate, though they cannot refuse to receive pauper patients, and it is certain that the hospitals which have attached fever wings will throw every difficulty in the way of the establishment of additional isolation hospitals.

Smallpox at Lincoln.

TWO cases of smallpox have occurred at Lincoln, 10th being traceable to Hull. Active measures have

been taken to prevent any spread of the disease in its new quarters.

A Timely Correction.

DR. CHARLES GOBING, surgeon in charge of troops on board s.s. *Sumatra*, writes to the *Times* contradicting the silly rumours to which the press have given currency concerning the pitiable plight of the sick and wounded recently repatriated in this vessel. He points out that most of the invalids were suffering from chronic diseases not entailing bodily discomfort, and, save some half-dozen who were landed in cots direct to the ambulance, they had nearly all recovered, and were all greatly improved by the beneficial effect of the voyage. We are pleased to assist in destroying a mischievous legend which, if left uncontradicted, might have produced a very unfavourable impression on the public at large.

Mysterious Death of a Medical Man.

AN inquest was held last week on the body of Thomas Edward Hughes, æt. 32, of Wandsworth, who died suddenly on the 4th inst. under somewhat remarkable circumstances. The deceased was stated to be in the habit of taking chloral and digitalis, the former in 40-grain doses, but the gentlemen who made the post-mortem examination came to the conclusion that death was due to commencing softening of the brain, with severe apoplexy associated with heart and kidney disease. A verdict was returned in accordance with the medical evidence.

Assistant Surgeons for the Army.

ACCORDING to the *Times*, the Secretary of State has had under consideration a despatch from the Government of India dealing with proposals for the creation of Army assistant surgeons, the necessity for whom has been brought prominently to notice during recent campaigns on the frontier of India. The inception of the scheme, drawn up by the military authorities at Simla, has met with Lord George Hamilton's approval, subject to certain minor amendments which will in no way affect the general principles.

University of London.

At the examination held during the present month, the following candidates passed in the Honours division:—

M.B. Examination: for Honours—Medicine.

FIRST CLASS.

Howard, Russell John (Gold Medal), London Hospital.

SECOND CLASS.

Beatty, James, Trinity College, Dublin.
Hilton, Caleb Thomas, Guy's Hospital.
Fugh, Charles Grant, B.Sc., Middlesex Hospital.
Scott, Sydney Richard, St Bartholomew's Hospital.
Thomson, Frederick G., Univ. Cambridge and Middlesex Hosp.
Van Praagh, Harold John, St. Mary's Hospital.

THIRD CLASS.

Hirst, Walter Clapham, St. Bartholomew's Hospital.
Stevenson, Mabel Geraldine, R. Free Hosp. & Lond. Sch. of Med.

OBSTETRIC MEDICINE.

FIRST CLASS.

Billington, William (Gold Medal), Mason C. and Queen's Hospital, Birmingham.
Iles, Mary Muriel Griffin, Royal Free Hospital.
Thomson, Frederick George, Univ. Camb. and Middlesex Hosp.
Unwin, W. Howard (Scholarship and Gold Medal), Charing Cross Hospital.

SECOND CLASS.

Barnes, Arthur Stanley, B.Sc., Mason C and Queen's and Gen. Hosp. Birm.
O'Dowd, John Austin, Birmingham Medical School.
Scott, Sydney Richard, St. Bartholomew's Hospital.
Stevenson, Mabel Geraldine, R. Free Hosp. and London School of Medicine.

FORENSIC MEDICINE.

FIRST CLASS.

Howard, Russell John (Gold Medal), London Hospital.

SECOND CLASS.

Barnes, Arthur Stanley, Mason College and Queen's and General Hospitals, Birmingham.
Martley, Harold, Owens College and Manchester Royal Infirmary.
Scott, Robert Gordon, St. Bartholomew's Hospital.
Strange, Robert Gordon, St. Thomas's Hospital.

THIRD CLASS.

Hilton, Caleb Thomas, Guy's Hospital.
Meachen, George Norman, Guy's Hospital.
Stevenson, Mabel Geraldine, Royal Free Hospital and London School of Medicine.
Turner, Philip, B.Sc., Guy's Hospital.
Vernon, Ethel Miller, London School of Medicine and Royal Free Hospital.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

SURGEON-MAJOR R.—The matter is hardly ripe for discussion at present, there is so much to be said on both sides that we prefer to await an official pronouncement before criticising existing arrangements. The matter will not be lost sight of.

X RAY.—A personal interview with the Medical Officer of Health would probably assist in removing this particular cause of friction. In matters such as these, the writing of letters often tends to engender controversies, whereas mutual explanations usually have for effect to place matters on a sound basis. If one would only eliminate the personal element, the administrative element would but seldom give rise to conflict of opinion.

DR. RYAN. You certainly ought to have notified the case, erysipelas being a notifiable disease, but it remains with you to avert any trouble on this head by abandoning what, in the light of your remarks, certainly appears to be a contestable diagnosis.

AN OPENING!

We call the following advertisement from the *Times* of the 11th inst.

"COULD any LADY OR GENTLEMAN tell a great sufferer from RHEUMATOID ARTHRITIS of any reliable RELIEF. No quacks, Baths, drugs, and doctors have failed. Address Grateful, A. 9, The Times Office, London, E.C."

Any lady or gentleman who knows of a cure for rheumatoid arthritis should come forward, for a fortune awaits the happy possessor of the secret.

MR. J. STRATTON (Wokingham). The correspondence is now closed, we cannot reopen the subject.

DR. CARTHEW DAVEY (Liverpool).—We hope to have space for your instructive case of Gastric Ulcer, Perforation and Ulcerative Endocarditis in our next.

DR. KESTEVEN.—From what you say the growth in the intestine is probably benign; 80 per cent. of such growths spring from the rectum, and they are for the most part polypoid in form. Occasionally these tumours, even when of large size, if situated higher up in the gut, give rise to no symptoms during life. The commonest signs and symptoms of polypi are tenesmus, hæmorrhage, difficult defæcation, sensory discomfort, and prolapsus ani. In all cases it is necessary to exclude the possibility of malignant disease.

Meetings of the Societies and Lectures.

WEDNESDAY, DECEMBER 20TH.

ROYAL MICROSCOPICAL SOCIETY (20, Hanover Square, W.).—8 p.m. Paper: Mr. E. J. Spitta: A Review of Photomicrography and its Different Methods (illustrated by numerous lantern slides).

ROYAL METEOROLOGICAL SOCIETY (Institute of Civil Engineers, Great George Street, Westminster, S.W.).—7.30 p.m. Ordinary Meeting. Papers: Mr. B. Latham: The Climatic Conditions necessary for the Propagation and Spread of Plague.—Mr. R. Scott: Note on a Remarkable Dust Haze Experienced at Tenerife, Canary Islands, February, 1898.

THURSDAY, DECEMBER 21ST.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road).—8.30 p.m. Dr. Watson Cheyne: Genito-urinary Tuberculosis.

Appointments.

CRAIG, WM., M.B., C.M. Glasg. Medical Officer for the Bolton and Thurnscoe Sanitary District of the Doncaster Union.

DENNING, J. V. C., L.R.C.P., L.R.C.S. Medical Officer for the Christchurch Workhouse of the St. Saviour's Union.

EDEN, THOMAS WATTS, M.D. Edin., M.B.C.P. Lond. Physician to Out-patients, Queen Charlotte's Hospital, London.

GOW, WM. J., M.B.C.P., M.B.C.S., M.D. Lond. Physician to In-patients, Queen Charlotte's Hospital, London.

GRIFF, WM. CHAPMAN, M.D. Edin., M.B.C.P. Lond., M.B.C.S. Consulting Physician to Queen Charlotte's Hospital, London.

HALL, B., M.D. Lond., M.B.C.S. Medical Officer for the Third Sanitary District of the Lendon and Winstreet Union.

HALL, H. S., L.R.C.P. Lond., M.B.C.S. Medical Officer for the Workhouse of the Leigh Union.

HANSON, R. J. E., M.B., C.M. Camb. Assistant Medical Officer for the Infirmary and Workhouse of the Parish of Paddington.

HARPER, JOHN MAURICE, M.B.C.S. Surgeon to the Bath Police Force.

HERRINGHAM, W. P., M.D. Oxon., F.R.C.P. Lond., M.B.C.S. Physician to Queen Charlotte's Hospital, London.

HIRST, G. S. S., M.B., C.M. Edin. Medical Officer for the Withern Sanitary District of the Louth Union.

JAFFREY, FRANCIS, F.R.C.S. Eng. Lecturer on Anatomy at St. George's Hospital, London.

NEWBERRY, W. J., M.B.C.S. Medical Officer for the Overton Sanitary District of the Whitechurch Union (Hants).

O'FARRELL, H., L.R.C.P., L.R.C.S. Ire. Medical Officer by the Guardians of the Portumna Union.

POLLOCK, WM. RIVERS, M.B. Camb., M.B.C.P. Lond., M.B.C.S. Physician to In-patients, Queen Charlotte's Hospital, London.

POMFRET, HENRY WATTS, M.D. Vict., F.R.C.S. Pathologist and Assistant Surgeon to the Ancoats Hospital, Manchester.

ROBERTS, CHAS. HUBERT, M.D., M.B.C.P. Lond., F.R.C.S. Physician to Out-patients, Queen Charlotte's Hospital, London.

STABB, ARTHUR FRANCIS, M.B., B.C. Camb., M.B.C.P. Lond., M.B.C.S. Physician to Out-patients, Queen Charlotte's Hospital, London.

STEPHENSON, SYDNEY, M.B. C.M., F.R.C.S. Edin. Ophthalmic Surgeon to Queen Charlotte's Hospital, London.

TAYLOR, SEYMOUR, M.D. Aberd., M.R.C.P. Physician to the West London Hospital, Hammersmith.

WHEELER, W. A., M.D., B.S. Irel. Medical Officer for the Milton Abbot Sanitary District of the Tavistock Union.

Vacancies.

Belmullet Union.—Medical Officer, £180 per annum as Dispensary Medical Officer, and £10 a year as Medical Officer of Health, together with Vaccination and Registration Fees. Applications to E. F. Flynn, Clerk of Union. (See advt.)

City of York.—Medical Officer of Health. Salary £400 per annum. Apply to the Town Clerk, Guildhall, York.

Dorset County Hospital Dorchester.—House Surgeon, to reside and board in the hospital. Salary £100.

Kent and Canterbury Hospital, Canterbury.—House Surgeon and an Assistant House Surgeon. Salary House Surgeon commencing at £90 with board, &c. Salary Assistant House Surgeon £50, with board.

Parish of Gairloch, Ross-shire.—Salary from the Parish Council £200 per annum, besides private practice. To reside at Poolewa. Applications to Mr. Macintosh, Inspector of Poor, Poolewa.

Queen's County Infirmary.—Medical Officer. Salary £182 6s. 2d. per annum. Applications to Geo. Dimond, secretary. (See advt.)

Seamen's Hospital Society, "Dreadnought," Greenwich.—Senior House Surgeon for the Branch Hospital, Royal Victoria and Albert Docks, E. Salary £75 per annum, with board and residence, and an additional £25 per annum conditionally.

Wexford Union. Medical Officer. Salary £100 per annum, and £15 as Medical Officer of Health, with the usual vaccination and registration fees. Applications to Nicholas Kehoe, Clerk of Union. (See advt.)

Births.

BAKER.—On December 12th, at 5, Gledhow Gardens, London, the wife of C. Ernest Baker, M.B. Cantab., F.R.C.S., of a daughter.

DRAKE.—On December 11th, at Lewisham High Road, New Cross, the wife of A. Thomson Drake, M.B., of a daughter.

Marriages.

FOY—MONTGOMERY.—On December 14th, at St. Martin's Church, Trafalgar Square, London. George Foy, Dublin, M.D., F.R.C.S., F.R.A.M., to Mary, daughter of the late Edward Henry Hellaby, of Rotheby, Leicestershire.

MARTIN—DICKSON.—On December 14th, at Ormond Quay Presbyterian Church, Dublin, by the Rev. Alex. Hall, M.A. Drogheda, Robert M. Martin of 5, Ulster Terrace, Stillorgan Park, Co. Dublin, son of J. B. Martin, J.P. Hellensburgh, Scotland, to E. Winifred Dickson, M.D., F.R.C.S.I., second daughter of the Right Hon. Thomas A. Dickson, Drogheda.

ROWAN—HIME.—On December 7th, at the Church of St. Mary Magdalen, Bradford, Major Henry Davis Rowan, Royal Army Medical Corps, son of the late Lieut. Col. Rowan, 34th Regiment, to Rosamund Hime, daughter of Dr. Thos. Whiteside Hime of Bradford.

RICHARDSON—BOWRING.—On December 12th, at Emmanuel Church, Clifton, Charles Boards Richardson, M.D., of Hove, Sussex, to Elizabeth, daughter of the late Benjamin Bowring, of Flash House, Mark Somerset.

SAWERS—BAILEY.—On December 12th, at St. Peter's Church, Stoke-on-Trent, John Lorimer Sawers, M.D., third son of the late Robert Orr Sawers, of Blackheath, to Charlotte, eldest daughter of Arthur Bailey, of Stoke-on-Trent.

VERNON—EWART.—On December 12th, at All Saints' Church, Margaret Street, W. Horace Middleton Vernon, M.A. Oxon., M.D., to Katharine Dorothea, elder daughter of the late Rev. Wm. Ewart, Vicar of Bishop's Canning, Wilts.

Deaths.

FLETCHER.—December 14th, at Ballinasloe, Mary Lynch Bloose, the beloved wife of N. V. Fletcher, F.R.C.S.I., and youngest daughter of the late Very Reverend the Honourable Robert Plunket, Dean of Tuam.

FROST.—On December 13th, at 30, Ladbroke Grove, London W., Charles Maynard Frost, F.R.C.S., aged 85.

RENTON.—On December 11th, at Shotley Bridge, Co. Durham, Geo. Renton, M.D. Edin., aged 56.

JAMESON. On December 14th at St. Catherine's, Blackheath, Geo. Wm. Jameson, Surgeon-Colonel Indian Medical Service.

THORNE.—On December 17th, at his residence Inverness Terrace, Hyde Park, London, Sir Richard Thorne, K.C.B., F.R.C.P. Lond. and Irel. F.R.S., Medical Officer to the Local Government Board, Aged 57.

The Harbican Lectures ON THE SURGICAL TREATMENT OF TUBERCULOUS DISEASES.

By W. WATSON CHEYNE, M.B., F.R.C.S., F.R.S.,

Professor of Surgery in King's College, &c.

ABSTRACT OF LECTURE II.

TUBERCULOUS PERITONITIS.—VARIETIES.

1. The peritoneum may be studded with tubercles of varying size, some small, greyish and transparent (the ordinary miliary tubercles), others larger and tending to become cheesy. These tubercles are scattered over both the visceral and parietal peritoneum, and there are frequently patches of fibrinous exudation over them which readily peels off, and in the early stage there is not necessarily any matting together of the intestines or shrinking or adhesions of the omentum or mesentery. The peritoneum is usually markedly hyperæmic. In these cases there is almost always more or less fluid present in the abdominal cavity, usually of a lightish straw colour, but in more acute cases somewhat opalescent or stained with blood. The sensation of putting one's finger into such an abdomen is the same as if it were passed into a bag of sago.

The tubercles are not usually distributed over the whole cavity, but are most numerous in patches, and this is more especially the case where the origin of the tuberculous peritonitis is some tuberculous lesion inside the abdominal cavity. For example in peritonitis originating from the tubes, the tubercles are most numerous in the pelvis, and become less numerous as one passes from it; or, again, in tuberculous peritonitis originating in connection with tuberculous ulcer of the intestines, the tubercles are in the first instance most numerous over the intestines in the neighbourhood and less numerous elsewhere.

Although, as has been said, in these cases the intestines are not usually matted together, still in some instances the fibrinous exudation produces sufficient adhesion to prevent the free spread of the fluid over the whole abdominal cavity, and thus we may have one or more collections of fluid simulating cystic tumours.

2. In a second set of cases the formation of adhesions and fibroid induration of the omentum and mesentery are the marked features. The intestines become bound together in masses by new fibrous tissue in which miliary tubercles may be present. These adhesions are often very firm, and may in parts constrict the intestines, or in other parts, from their shrinking, lead to kinking of the intestine, and in both ways they may cause partial or even complete obstruction. Further, the intestines are not only adherent to one another, but they are also very apt to contract adhesions to the abdominal wall, and this

forms a great difficulty in performing laparotomy in these cases, and it is also the great objection to aspirating the abdomen where fluid is present. Where the whole abdomen is involved, these adhesions are especially marked between the liver and diaphragm. The omentum is also early involved in these fibroid changes, the two layers of the omentum become matted together, and the whole structure becomes much thickened and shrunken, and in an advanced stage forms a thick rolled-up mass like a sausage lying about or above the level of the umbilicus, and usually running more or less transversely across the abdominal cavity; it is generally adherent to the abdominal wall at this part. This thickened omentum contains numerous tubercles in its substance and scattered over its surface. The mesentery is also markedly affected with similar changes, and becomes thickened and shrunken and drags the small intestine up towards its root, and thus it comes about that when fluid is present it is most apt to collect towards the left side and lower part of the abdomen. The mesenteric glands are also enlarged, but not as a rule cheesy.

In these cases a certain amount of cirrhosis of the liver may even be met with, or there may even be tubercles in the substance of the liver. The spleen also is not uncommonly enlarged, either as the result of passive congestion or hyperplasia, or in some cases from the presence of tubercles. This adhesive form of tuberculous peritonitis may or may not be accompanied by the presence of fluid, and where fluid is present it is most often encapsuled, and there may be more than one collection.

3. A third condition which may be present, and one which is extremely grave, is that the tubercles run together and form large masses which undergo caseation; the mesenteric glands are enlarged and caseous; the omentum is often converted into a caseous mass, and caseating masses form in the adhesions which bind the intestines together. The contractions and distortions of the intestine and the shrinking of the mesentery and the other changes mentioned under the second form are usually much exaggerated. This condition is especially associated with intestinal ulceration, and the intestine is usually thinned, and may even be perforated. Collections of fluid are frequently present, most usually encapsuled and multiple, and not uncommonly purulent. The pus may present all the characters of ordinary tuberculous pus, but in other cases it may be foul smelling, either as the result of infection through the intestinal walls, or as the result of actual perforation of the intestine. In this form, in infants especially, the condition may be most marked in the neighbourhood of the umbilicus, and the pus may make its way through the abdominal wall at this point. Where this occurs we find a sinus passing into the abdomen, and not uncommonly a fecal fistula is present as well. As this fecal fistula is usually in the small intestine, and often pretty high up, the child rapidly emaciates and goes down hill.

In both the second and the third forms the upper part of the abdominal cavity may be healthy, the disease being shut off above by the adhesion of the omentum to the abdominal wall at the level of the umbilicus. In other cases it may be still more circumscribed, and form a limited patch with fluid in the interior, this condition being most commonly met with in the form of an irregular fluctuating swelling in the left iliac fossa. Another local form is where it is limited to the pelvic region, which occurs especially in connection with infection from the Fallopian tubes; or, again, we may meet with a tuberculous perityphlitis forming a mass in the right iliac fossa, which has been mistaken for a malignant tumour. These masses are usually secondary to tubercle of the appendix or cæcum.

There are many intermediate forms and varieties of these pathological changes which it is impossible to enumerate here, but these are the three chief types, and they are of especial importance from the point of view of treatment.

SYMPTOMS.

The commencement of the disease is usually insidious and slow, although in some cases it may be rapid, and may then be mistaken for typhoid fever, tuberculous peritonitis, etc. In most cases the early symptoms are quite indefinite. The patient has a feeling of malaise and weakness, he is subject to headache, may suffer from thirst, does not sleep well, and frequently has night sweats. He soon begins to lose his appetite, feels out of sorts, and not uncommonly has occasional vomiting. The bowels are irregular, he frequently suffers from obstinate constipation or from diarrhoea, or again from alternate constipation and diarrhoea. By-and-by he begins to have occasional abdominal pain, especially of a shooting character, or, it may be, only a feeling of weight or pressure. In other cases there is no pain at all; indeed, it is very seldom that pain is severe at the commencement of the trouble. The pain if present is increased by exertion. The temperature is very variable; there is generally an evening rise, but it may not be marked; in a good many cases there is no rise at all, the temperature being normal, while in others again, after it has been normal for some time, it may suddenly commence to rise in the evening and assume a marked hectic type. In the early stage, except in the acute cases, the patients are able to go about, or even follow their employments, but from time to time they may have to lie up on account of feeling out of sorts, or of general weakness, or of increasing pain, and then, after a few days' rest, they are able to go about again. After some weeks or months, however, the patient has to give up work either on account of increasing weakness, or more commonly on account of gradual swelling of the abdomen, a feeling of weight, or more rarely severe pain, shortness of breath, &c. As the disease goes on the general symptoms increase, there is a rapid advance in the malnutrition and emaciation, the skin becomes pale and sallow and dry, the cheeks sink in, and the patient acquires the suffering aspect of those with abdominal trouble. In others, again, the symptoms are much more acute, and in a considerable number of cases they have been mistaken for those of typhoid fever.

On examining the abdomen the condition of matters present depends on the pathological changes already described, and to a great extent also on whether there is or is not fluid, and on whether the fluid is free or in loculi. Where there is much free fluid present the abdomen is distended, somewhat flattened at the sides, and the ribs everted. The abdominal wall is stretched and shining, with big veins running over it, and it is usually so tense that nothing can be felt through it. The pain is no

generally marked in these cases. Where the fluid is less the thickened omentum is readily felt in the form of a tumour-like mass of a sausage shape generally running more or less transversely across the abdomen about or just above the level of the umbilicus, the omentum being thickened and rolled up by the fluid and the distended intestines, and pressed against and becoming adherent to the abdominal wall. The percussion note is uncertain and atypical, fluctuation is not distinct, and the fluid as a rule only changes its position slowly, owing to having to make its way among the adherent intestines. Under other circumstances, again, the fluid may be more or less completely encapsuled and form definite fluctuating tumours, which may be mistaken for ovarian or other cysts. On the other hand, there may be little or no fluid present; the coils of intestine become adherent, the mesentery contracts, the omentum is thickened and shrunken, and hard bands and thickenings are found in the abdomen. Thus one may not only feel the thickened omentum, but also definite patches of hardness elsewhere, due to these bands and thickened adhesions, or one may find more definite hard tumours which are generally composed of masses of glands or of thickened adhesions studded with tubercles, or of small collections of encapsuled fluid. The abdomen is uneven, owing to irregular distension of the intestinal coils with gas. There may be marked meteorismus, and, when the intestine is kinked or in any other way obstructed, the coils of contracted intestine may be seen through the abdominal wall. In the latter case, of course there would probably be other signs of obstruction. The splenic dullness, if it can be made out, may be increased. The liver dullness is not commonly diminished, but, on the other hand, the liver may be enlarged as the result of early cirrhosis or fatty infiltration. There is often decrease in the quantity of the urine, and not infrequently albuminuria. The stools are frequently light in colour, due to imperfect digestion of the fat.

It is not uncommon for the disease to be associated with various complications, more especially with intestinal obstruction due to kinking, bands, or narrowing of the lumen in connection with ulceration; or, on the other hand, perforation may occur, either through the ulcer or above an obstruction; or, again, we may have inflammation and thickening around the umbilicus, especially in children, which has been already referred to, and which is pathognomonic of tuberculous peritonitis. In bad cases belonging to Type III., where suppuration is present and emaciation usually rapid, there is generally considerable fever, and the patient quickly goes down hill. It is not uncommon for the disease to be combined with phthisis, or with pleurisy. Schreiber gives 26 cases, of which 12 had already tuberculous pleurisy; and Heintze in 25 cases had 20 with pleurisy. Although not as a rule so frequently present, pleurisy is nevertheless not at all an uncommon accompaniment; it may precede the peritonitis, or the two may begin simultaneously, or more commonly the pleurisy comes on after it. It often sets in insidiously, and in any case it is grave and increases the dyspnoea.

SURGICAL TREATMENT.

The value of surgical measures was found out quite accidentally. In 1862 the late Sir Spencer Wells, in operating on what he supposed to be an ovarian cyst, found on opening the abdomen that he had before him a case of tuberculous peritonitis. He therefore at once closed the wound again, but to his surprise the patient soon began to improve, and ultimately got well, and was alive and well twenty-five years later. As abdominal surgery became more and more developed similar mistakes were frequently made, and further, as exploratory operations were

introduced, tuberculous peritonitis was not uncommonly discovered. It was found that in a considerable number of cases after such mistakes or explorations the patients rapidly got well, and by-and-bye it became clear that this could not be regarded as a mere coincidence but that laparotomy had a distinctly beneficial effect in a considerable proportion of cases of tuberculous peritonitis. Hence surgeons began to perform laparotomy as a curative measure in cases which were diagnosed as tuberculous peritonitis, with results which have established it as a highly successful means of treatment.

Prognosis of Laparotomy.

The prognosis of laparotomy naturally varies in different cases. The most favourable are certainly those belonging to the first group, with localised ascites, and the next most favourable are those where the fluid is diffused over the abdomen. I must confess that I have been surprised at the recovery in some of these cases. On opening the abdomen one finds tubercles everywhere, the intestines protrude from the wound and are seen to be red, inflamed, and covered with tubercles, some of them sometimes of considerable size, the abdominal cavity feels like a bag of rice, and yet in these cases recovery may follow. In two instances in which I gave a very bad prognosis after the operation, on account of the size and number of the tubercles scattered all over the intestine and abdominal cavity, recovery took place rapidly and apparently completely. The next most favourable cases are those where there is no ascites and where we have the fibro-adhesive form to a moderate extent as described under heading No. II. Indeed favourable results have been obtained in this form even where the adhesions were so great that the operator never penetrated into the abdominal cavity. By some this fibro-adhesive form is looked on as a healing process, and it is held that the operation probably merely gives it a fillip in a good many cases. Where the abdomen contains large caseating masses the prognosis is much more grave, and as is evident from the results mentioned above the successes are not nearly so great. At the same time they do occur, and I myself had a successful result even when there were large masses of caseating material. In this group however it is rather the case of giving the patient a chance than of any great probability of curing him. It must also be borne in mind that it is in these cases more especially that harm may be done by the operation, for unless great care be taken the intestine may be readily torn and a faecal fistula be established. Indeed in some instances, even when there is no apparent injury to the intestines, a faecal fistula may result after the operation. In these cases it is not uncommon to find that the scar breaks down subsequently, having become infected with tubercle, but even in spite of this healing may ultimately occur in time where a faecal fistula has also formed, provided always that it is not large nor situated high up in the small intestine.

Cases with slight phthisis also frequently improve both locally and also as regards the lung after operation, but where the phthisis is extensive the result is not good. Opinions differ as regards the effect of pleuritic effusion on the results of operation, but as a whole it is not looked on as a contra-indication. Cases with intestinal ulceration are particularly unfavourable, and it is a question there whether laparotomy does any good. Spæth also asserts that cases secondary to tubal disease are not benefited by laparotomy, even although the tubes are removed, but this is contrary to the experience of Aldibert and of a number of other observers who have obtained good results even where the tubes were not touched. The great risk of tuberculous peritonitis in these

cases of tuberculous salpingitis, however, makes it essential that where a diagnosis of tuberculous salpingitis is made the tubes should be removed at once.

Time for Operation.

From the evidence, I should say that in practically all cases where improvement does not follow under medicinal treatment after a reasonable time, say in from four to six weeks in acute cases, to four to six months in chronic cases, the abdomen should be opened whether there be ascitic fluid or not. The operation may do good in cases where it is least expected to do so, and it is but seldom that it does any harm. Do not in any case allow the patient to go down hill too much, otherwise one cannot expect good results to follow, and it is fair neither to the patient nor to the surgeon. It seems to me a very questionable thing whether it is good for the patient that the ascitic fluid should be absorbed seeing that it contains toxins and bacilli, and therefore, as I have said, where improvement does not follow soon I believe that early laparotomy is best, and the medical treatment can follow the operation just as well, or better, than if it precede it.

On the other hand, it apparently does not do to operate too soon. Where one operates quite in the early stage, recurrence curiously enough is very apt to take place, and the explanation of this I believe to be that which I shall give presently in connection with the *modus operandi* of the operation. However it may be explained, it certainly is the fact that most of the cases where repeated operations for recurrence have taken place have been those in which the first operation was performed quite at the commencement of the disease. On the other hand, it is most important not to wait till the patient has gone too far downhill. If the patient suffers pain from bands, or from kinking of the intestine, or from obstruction, operation is necessary, even although much good may not result.

The Operation.

In operating, as has been before stated, it is well not to attempt to carry the procedure to the extent of attempting to remove any of the diseased tissues, such as excision of an ulcer of the intestine, the removal of tubes, etc.: unless, indeed, one finds only quite a commencing peritonitis at that part. The removal of the tubes, for example, in cases of advanced peritonitis would mean a prolonged and very difficult operation, owing to the adhesions, in a peritoneal cavity already very much inflamed, and one which would almost certainly precipitate the patient's death from shock. On the other hand, if on opening the abdomen one finds only slight commencing peritonitis around the tubes, then I believe they ought to be removed so as to prevent further infection. Similarly, in the case of the appendix or cæcum, while a few cases have improved as the result simply of opening the abdomen, the best results have been obtained in cases where the disease has been localised to that region, and where the appendix or the cæcum itself has been resected. On the other hand, in cases with intestinal fistula, operation is out of the question. The patient cannot stand a proper operation for resection of the fistulous portion, and the intestine in the neighbourhood of the fistula is usually so thinned and diseased that any attempt to stitch up the whole without resection practically always fails, and such attempts leave matters worse than they were before. Lastly, it may be said that if one is in doubt it is better to operate than to leave things alone.

Some, thinking that the beneficial effects of laparotomy were simply due to the evacuation of the fluid, have concluded that the same result could be obtained by aspirating the abdomen. This, however, does not seem to be the case; good results have cer-

tainly in a few cases followed puncture with evacuation of the fluid and injection of air, but simply tapping the abdomen seems to be quite inefficacious. Further, puncture of the abdomen is a procedure by no means free from danger in these cases. It is not at all uncommon for the intestine to become adherent to the abdomen in the middle line, and cases have occurred where it has been punctured by the trocar, and the death of the patient has resulted. Hence, partly on account of its inefficiency and partly on account of its danger, puncturing the abdomen should be given up as a means of treatment.

The operative procedure is very simple in most cases. Where effusion is present without adhesions it simply consists in opening the abdomen in the middle line, below the umbilicus, allowing the fluid to run out, aided by turning the patient on his side and perhaps removing some of it by means of sponges, and then stitching up the wound again. In former days the abdomen was washed out with various antiseptic solutions, such as carbolic acid, sublimate, etc., some leaving the solution in, other flushing out the abdomen afterwards with salt solution. Others again very carefully dried the cavity as far as possible with sponges and so forth. All this seems, however, to be unnecessary, and in reality inadvisable, for as good results are obtained by simple laparotomy without the introduction of any chemical substance at all, or even without flushing out the abdomen or complete removal of the fluid, as where these measures are adopted.

Where adhesions are present, care must be taken in opening the abdomen not to injure the intestine, and if the adhesions are firm it is better to leave them alone and close the wound than to try to force one's way in, unless fluid be present.

In the dry fibrous form, unless the intestine is becoming kinked or bound down by adhesions, it is seldom advisable to try to separate the coils on account of the risk of weakening the wall of the bowel, and consequently leading to a faecal fistula. If, however, obstruction is present it must be relieved or an anastomosis must be made between the coils above and below. Should a rent occur in the peritoneal coat in the course of such an operation it should be very carefully stitched up.

When pus is found it should be washed out by salt solution, and it is then well to introduce a little iodoform and glycerine emulsion into the cavity before closing it.

The question of drainage has been raised in these cases, but there does not appear to be any advantage in drainage where the fluid is serous, and there is the disadvantage that in some cases it has happened that a tuberculous sinus has been left at the seat of the drainage tube. Even where pus is present, unless it be foul-smelling, it seems best to treat it like a chronic abscess elsewhere by washing it out thoroughly, injecting a little iodoform and glycerine, and closing the wound again.

An important point arises—namely, whether a primary focus such as a tube or appendix, etc., if found, should be removed. This, as I have already said, depends very much on the extent of the disease. If the whole peritoneum is infected, then no attempt should be made to remove the primary focus, such attempts having generally ended disastrously. On the other hand, if the tuberculous peritonitis be limited to the immediate vicinity of the tube or appendix and cæcum, the removal of the primary source is very important, and much better results are obtained by so doing than by simple laparotomy.

As regards the course followed after laparotomy, in some cases immediate improvement begins, while in others ten days or longer may elapse before any noticeable effect is produced. In any case medicinal measures should be superadded to the surgical as

soon as possible. In some cases the fluid reaccumulates, and there is then no objection to a subsequent laparotomy; indeed, as has been already said, there are some instances where several laparotomies were performed and where cure was ultimately obtained.

GASTRIC ULCER: PERFORATION—RECOVERY; ULCERATIVE ENDOCARDITIS—DEATH.

By W. H. CARTHEW DAVEY, F.R.C.S.E.,
Hon. Surgeon, Boys' Orphan Asylum, Liverpool.

MRS. A., æt. 22, married, two children, the youngest child born October 2nd, 1898, the confinement passed off satisfactorily, and the recovery quite uneventful, the patient then left home for some time, and I did not see her again till April, when I was shocked at her appearance. From being a strong, robust, healthy woman she was thin and wasted, and complained of weakness and general debility, with dyspeptic symptoms, flatulence, pain after food, &c. (there was no vomiting). The case appeared to be one of flatulent dyspepsia brought on by nursing and worry and anxiety about the baby. The child was accordingly weaned, and the dyspeptic symptoms treated with soda and bismuth internally, and a restricted milk diet. Matters improved very considerably under this treatment until the evening of May 22nd, when the patient had eaten somewhat heartily of supper. No discomfort was felt at the time. She retired to bed at the usual time feeling quite comfortable. At about 2 a.m. the patient was seized with violent abdominal pain and vomiting. The husband, thinking it was an ordinary bilious attack, did not send for me at the time, but gave some brandy. This was promptly ejected. The patient being no better I was telephoned for between 5 and 6 a.m., and on arrival found the patient in a state of collapse and pain. (The vomited matter had unfortunately been thrown away, but it was described to me as quite black in colour.) On examining the abdomen there was an area of tenderness and dullness in the left hypochondriac region, no general abdominal distension. I concluded we had most likely a case of perforating gastric ulcer to deal with. Now, how were we to deal with the case. Operate at once, or opium and starvation. I chose the latter treatment because I believed that the extravasation, if any had occurred, had become localised owing to old adhesions. I, therefore, injected morphia hypodermically, and commenced rectal feeding, nothing allowed by the mouth. This treatment was continued for ten days, the temperature during this period remaining between 100 and 102 degs., until the eleventh day it reached the normal point. A little peptonised milk was now given, but we had a recurrence of pain and rise of temperature. It was quite evident we must again go back to starvation, and this was accordingly done for another ten days, the patient bearing her deprivation of food most kindly and with great fortitude. We had now reached three weeks from the primary attack, and felt justified in again attempting nourishment by the mouth, peptonised milk was again given, and no trouble arose from the venture: the quantity was gradually increased, and at the end of another week we were able to give a little fish and chicken, and matters appeared to be shaping most favourably (the dullness still remained in the left hypochondriac region), the patient was able to sit up and was hoping to get out in a few days, when the temperature again began to rise, and parotitis of the left gland came on. This was followed by the right gland becoming inflamed; this gradually subsided, but left facial paralysis remained. Another difficulty

had been overcome, when all our hopes were shattered by left hemiplegia presenting itself. It was now pretty evident that we had a case of septic poisoning to deal with. It was most disappointing, one trouble after another. Temperature during this period oscillating between 99 and 103 degs. The hemiplegia gradually improved, and the case looked more hopeful, when we had another hemiplegic attack, and about this time a very faint murmur was heard over the aortic region of the heart, and what we feared had occurred, the valves of the heart had become involved in the general septic poisoning, and the case was now hopeless, the patient gradually got weaker, the wasting continued, and in spite of all treatment, she died in the middle of September after four months' illness borne with great patience and fortitude.

ON THE EXAMINATION OF SICK CHILDREN. (a)

By LANGFORD SYMES, F.R.C.P.I., ETC.,

Physician to the Orthopedic Hospital in Ireland; Physician to the Convalescent Home, Stillorgan; Physician to the Homes for Destitute Children, &c., &c.

(ABSTRACT).

THE clinical examination of sick children differs in some respects from that of adults, and as their diseases, symptoms, and treatment are in many ways diverse, it occurs to me that it might be useful for us to consider to what special points in their case particular attention should be directed—what peculiarities strike the physician in his visits to the children's ward.

Young children never know the seat, nature, or cause of disease. Their friends often mislead one, being themselves in ignorance, and so its discovery is entirely dependent on the physician's powers of physical examination. Hence it necessarily follows that every organ should be examined.

The method or routine which I have been led to adopt, and find useful, has this advantage at least, that once the physician's hands are laid upon the child the whole examination can be gone through without their ever being lifted off. In this procedure the child, if in bed, must be stripped quite naked and rolled in a blanket; and if in the out-patient department, for the first visit, should be undressed by a nurse in the ante-room, and sent in to the physician clothed only in a long flannel dressing-gown. Before proceeding to examine any child it is of great importance to know the history. The following history is a rough sample of what should be obtained from the mother or person in charge, for the patient is quite unable to assist one. It differs in many respects from that obtained from adult patients:—

History.—What the child has been brought for? How long ailing? When last quite well? Beginning, cause, or progress of illness? If born properly or prematurely? Particulars of labour and condition after birth? (by this inquiry premature birth, hæmatoma, visceral, or mucous hæmorrhages, asphyxia, obstetric paralyses, umbilical conditions, septic infections, icterus, nystop, neonatorum, tetanus neonatorum, or mastitis will be fully revealed). How long fed at the breast, and when first given artificial food? How much? How often? How mixed? When weaned? (by these questions we can often discover the causes of some of the most fatal diseases of children—marasmus and atrophy, rickets, scurvy, diarrhoea and dysentery, flatulent colic, and dilatation of the colon). Commencement and progress of dentition? What previous diseases, and when (especially we should inquire for thrush, rashes, snuffles, diarrhoea, fits or convulsions, whooping-cough, mumps, diphtheria or croup, rheumatism or growing pains, and infectious diseases). How many other children living? Their health? Children lost (causes)? Miscarriages (for syphilis)? Mother's health and history (especially for

rheumatism, syphilis or tubercle)? Father's health and history (rheumatism, syphilis, tubercle), and, lastly, the hygiene or sewerage of the house?

All these particulars throw a vast amount of light upon the case, and should be in writing on the notesheets at the head of each child's bed, and obtained by the clinical clerk on its admission from the mother or friend before they are allowed to leave the hospital.

Examination.—The following order is recommended:—

I. "*Facies.*"—The general appearance of the child is to be first noted—pale and anæmic, florid, sallow or jaundiced in complexion; fat and well-nourished, or pinched and wasted; well developed or dwarfed; joy or sorrow; pain or ease. The attitude, if at ease, distorted, choreic, paralytic, or anywise crippled. The gestures; how it receives objects, &c. Its sanity and intelligence, and state of cerebation (idiocy, cretinism, moral insanity, or mania will be evident). Conscious or comatose (drowsiness and stupor in children may result from uræmia, epileptiform convulsions, organic cerebral disease—such as hæmorrhage, effusion, abscess, or tumour; hydrocephaloid condition in summer diarrhoea, ptomain or food poisoning, formerly called gastric attacks, and sometimes from pneumonia, drugs, or alcohol). If it cry or cough the voice will reveal its pulmonary and laryngeal condition (for instance, it may tell us of whooping-cough, diphtheria, laryngitis, laryngismus, or pneumonia). Again, œdema, cyanosis, skin affections, or eruptions are at once obvious; also the rashes of purpura, chicken-pox or infectious fevers. Respiration is visible. The physiognomy alone often reveals disease (e.g., chorea, pleuro-pneumonia, meningitis, "hippocratic facies" of impending death, adenoids, Bright's disease; wasting of diarrhoea, atrophy, or marasmus, with Jadelot's lines on the face; inherited syphilis, with its rash, snuffles, fissures, or "Hutchinson's teeth," &c.). The state of the ocular muscles and pupils are usually easily observed, and may reveal paralysis from cerebral abscess, cerebral tumour, thrombosis of sinuses, tuberculous meningitis, or diphtheritic paralysis.

II. The child being now stripped next pass both hands carefully over the head. Observe if sweating exists (as in rickets). Note its size and shape—whether microcephalic, hydrocephalic, rickety, or "natiform," with "bosses" or osteophytic nodes on the surface of the bones. The sutures may be prematurely closed (microcephalus), unduly patent (hydrocephalus, rickets), or grooved. The anterior fontanelle, usually closing about the eighteenth month, may be obliterated too early (microcephalus); widely open, with resilient attenuated edges (hydrocephalus, rickets, cretinism, achondroplasia, formerly called foetal cretinism, and in some dwarfs); tense and prominently bulging (meningeal effusion, hydrocephalus, cerebral tumour, whooping-cough, posterior basal meningitis, bronchitis): flat or deeply sunken and depressed (collapse, diarrhoea, cholera infantum, "hydrocephaloid" condition, wasting diseases, malnutrition), "Craniotabes" may be felt—i.e., thinning of the occipital bones so as to yield under the pressure of the finger (indicating syphilis, rickets, chronic hydrocephalus). Measurements of the head are also necessary in some of its diameters in correctly estimating mental capacity.

III. The hands now pass down from the head and examine the entire frame, bones, and joints. The shoulders, arms, hands, fingers, chest, ribs, hips, legs, and feet. (Rickets, scurvy rickets, rheumatism with its subcutaneous nodules, torticollis, clubbed fingers, deformities, joint affections and bone diseases, sarcoma, erythema nodosum, œdema, chilblains, and pseudo-hypertrophic paralysis are thus at once observed).

IV. The reflexes are easily commenced next, as the hands are now touching the feet. Plantar, "ankle clonus," knee-jerks, cremasteric, abdominal, epigastric, facial irritability (for tetany), and ocular reflexes. The reflexes are a most valuable index to the state of the nervous system in infants, and neuritis, chorea, diphtheritic paralysis, infantile paralysis, Friedreich's disease, meningitis in its many forms, spastic paraplegia (cerebral paralysis), birth palsies and hemiplegia can frequently be differentiated thereby.

(a) Read before the Royal Academy of Medicine of Ireland.

V. The eyes should now be scrutinised—pupils, ocular paralyses, vision, photophobia, nystagmus, &c., The ears for otorrhœa, &c., and the nose for snuffles (a common sign of syphilis), ichorous discharges, depressions, adenoids, &c.

VI. The glands are now commenced:—Parotid, cervical and submaxillary, thymus and thyroid, supraclavicular, axillary and inguinal; showing perhaps mumps, Hodgkin's disease, tubercle, sarcoma or new growth, syphilis, glandular fever, or with an atrophied thyroid myxœdema or cretinism.

The hands will now lie upon

VII. The abdomen; the gentlest palpation possible will alone reveal its true condition. First observing the intestines we look especially for abdominal tubercle, tuberculous peritonitis with bands of lymph, tuberculous ulceration of the bowels, enlarged mesenteric glands or tabes mesenterica, ascites, tumours, intussusception, constipation or dilatation of colon. Next we measure the liver by finger-breadths below the costal arch and feel its edge. It is relatively larger in infants than in adults, while its diseases are not so common. Then the spleen may often be felt and measured. Enlarged spleen in infants is common in splenic anemia (a), rickets, tuberculosis, and perhaps syphilis. The kidneys should also be sought for, and if felt some morbid condition has either enlarged or displaced them, as they should not be felt in health, sarcoma, new growth, or cystic disease here occur to the mind.

In connection with special abdominal diseases the rectum must be examined, but as a routine practice it is not, perhaps, required.

VIII. The heart is now quite close; see its apex beat; feel its impulse or thrill; map out its area of dulness. Enlarged area of cardiac dulness in children occurs in chorea, pericarditis, diphtheritic paralysis, rheumatism, some cases of congenital heart disease, and whooping-cough. In an epidemic of whooping-cough last spring I found a remarkable increase in the cardiac dulness. Appreciate its sounds, and detect its murmurs—functional, organic, or congenital. Congenital heart disease consists of patent ductus arteriosus; patent foramen ovale, or, most commonly, a deficiency of the ventricular septum. It will be known by cyanosis and clubbing of the fingers; loud, musical systolic murmur; feeble apex beat, usually absence of thrill; and its occurring in a child under three years old.

What is termed Eustace Smith's sign may sometimes be heard at this juncture—i.e., a murmur over the manubrium on bending back the head, usually indicating enlarged bronchial glands.

IX. The lungs are now beneath the hands—anterior, superior, sides, posterior. Especially look for atelectasis or collapse, broncho-pneumonia, with its miniature patches of dulness so difficult of detection, and empyema. Tuberculous lobular pneumonia is also a very violent disease in children. Of all lung diseases, however, one of the most peculiar is that known as "Apex Pneumonia," very masked, resembling enteric fever, with delirium, convulsions, and very little to show, it is liable to be passed over. It was called from its delirium "cerebral pneumonia," but as shown by Dr. Sturges it is only because the other signs are less that the delirium is more striking. The child will now for the first time be sitting up, and when the posterior portions of the lungs have been examined, glance next at

X. The spine. Test its curves, prominences, depressions, suppleness, or rigidity. Especially we must beware of rickety curvature of the spine distinguished from Potts' disease—by forming a wide curve, disappearing on lifting the child, and by being unaccompanied by pain or much stiffness. Also we must recollect paralysis of the muscles of the back from diphtheritic paralysis, tumour of the cord, or anterior poliomyelitis.

XI. The neck is an important part of the spine. It

reveals wasting in a child at once. Also rigidity of the neck in children is a very striking symptom. It may occur in tuberculous meningitis, purulent meningitis, posterior basal meningitis, cerebellar tumour, enteric fever, diphtheria, apex pneumonia, wasting with dyspepsia, tetany, retro-pharyngeal abscess, cervical caries, rheumatism, &c. When severe it produces retraction of the head and "cervical opisthotonos."

XII. The mouth is now finally inspected. See the lips, gums, teeth, tongue, cavity of the mouth, palate, tonsils, and throat, and, if suspected, examine for adenoids. A host of diseases previously unthought of may be revealed in a child's mouth—thrush, scurvy, stomatitis, and cancrum oris; delayed or irregular dentition from cretinism, rickets, syphilis, or retro-pharyngeal abscess; also follicular tonsillitis and diphtheria, laryngitis and laryngismus may have to be differentiated.

This usually finishes the routine examination in ordinary cases, and is generally sufficient to establish a correct diagnosis, or at least, reduce the difficulty to one of two alternatives. Thus in the passage of the hands from the head twice down and up the body, the fullest information can be quickly gathered from examination of the various organs *en route*, while the hands are never taken off the child.

XIII. Special investigation of the nervous system must, however, be afterwards conducted if any suspicion remains, or if the foregoing examination reveal any nervous troubles.

The following are the chief points, being the same for both adults and children:—

1. Motor phenomena—*e.g.*, spasm, paresis, paralysis, tremor—power of shutting eyes, whistling, laughing, grinning or frowning; power of co-ordination, threading needles, passing needle through a hole in paper, touching the nose, standing with eyes shut, etc.
2. Reflex phenomena, especially seeking for diphtheritic paralysis, infantile paralysis or neuritis.
3. Sensory phenomena—*e.g.*, touch, pain, heat, cold.
4. Trophic phenomena, particularly regarding pseudo-hypertrophic paralysis, juvenile muscular atrophy, birth palsies, infantile hemiplegia, or spastic paraplegia.
5. Electrical phenomena.
6. Bladder phenomena; control of sphincter. Incontinence of urine is often caused by stone, phymosis, uric acid, worms, or organic nervous disease.
7. Rectum phenomena, control of sphincter.
8. Mental capacity for feeble-mindedness, idiocy or imbecility, cretinism, moral insanity, mania, and even general paralysis of the insane (of seventy-two cases collected under twenty years by M. Thiry, twenty-nine were under fourteen years of age).
9. Speech, for backwardness, aphasia, nasal speech, stammering, idioglossia, or even dumbness.
10. Power of sitting, standing, walking, reading, writing, or singing. It is remarkable that in some cases of cerebellar tumour in children they can sing very well.

Some other points in clearing up the clinical puzzles of children's diseases can be subsequently tested—*e.g.*, the urine, the rectum and anus, and alvine discharges (for worms, diarrhoea, dysentery, prolapse or syphilis). Blood estimation, the ophthalmoscope, vision, and colour-blindness, the weight to show nutrition, the height for stunted growth, measurements of the head, further investigation of the mental capacity, special electrical reactions, and the use of the dynamometer, aesthesiometer, or other of the numerous psycho-physical instruments.

Every physician must choose his own method of examination; but the advantage of the above plan is, that the hands, once placed upon the child, need never be removed until the entire investigation is complete.

The recollection of these points as we enter the children's ward will materially assist us in our research. It is, doubtless, frequently true in the practice of medicine that we make mistakes, not because we do not know, but because we do not examine, and in the diseases of children this is eminently the case.

The medical examination of a sick child requires con-

(a) I would here remind you that splenic anemia was first depicted by an Irish observer, Dr. Francis Battersby, Surgeon to the Institution for Diseases of Children in Pitt Street, Dublin, who published his careful observations in the "Dublin Quarterly Journal" of May, 1849, as "Tumefaction of the Spleen in Children." Continental and English observers have since confirmed many of his results. It occurs among the wealthy classes just as in poor children.

siderable dexterity. I do not wish to convey the idea that the examination of an adult is an easy matter. Far from it. But what I do wish to say is, that however difficult the examination of an adult may be, that of an infant is more so. Nay, more; I might say without fear of contradiction, that there is no branch of the practice of medicine in which clinical examination must be brought to such a pitch of refinement as in the diseases of children.

It forms, in my opinion, the very best, although severest, school for the clinical investigation of disease, and as a training ground for senior students it cannot be surpassed—a study as instructive in education as it is interesting in research, and useful in practice.

Clinical Records.

CASE OF CÆSAREAN SECTION.

By Dr. G. COLE BAKER,
of Dublin.

I AM enabled to bring before you a successful case of Cæsarean section in which I performed this operation successfully, in August last, on a woman parturient for the eleventh time. I believe that in this fact my case is unique, though Murdoch Cameron (Glasgow) has performed it on a nine-para, whose eight previous pregnancies had been terminated by craniotomy.

The history of the ten previous labours is somewhat remarkable. The 1st, 4th, and 5th were terminated by forceps. Result to the child:—1st stillborn, 5th died in four hours, 4th alive, and now eleven years old. At the 2nd and 10th labours, forceps having failed, version was performed, but in both cases the after-coming head was only extracted by perforation and craniotomy. The 3rd, 6th, 7th, 8th, and 9th labours terminated naturally, resulting as follows:—In the 3rd and 8th the children were alive, and are still living; the 6th was stillborn, while the 7th and 9th both died a few minutes after birth. Aware that the woman had had living children, I allowed the patient to remain in labour for forty hours before I interfered, in the hope that the head might mould and the child be extracted. At the end of this time, however, as the mother's pulse and temperature were rising, the lower uterine segment thinning out, and the contraction ring becoming marked, the foetal heart sounds increasing in frequency, with a "caput" commencing to form without any symptoms of moulding, I asked Dr. W. J. Smyly (ex-Master of the Rotunda Lying-in Hospital) to see the case with me, and we mutually agreed that the choice lay between Cæsarean section and craniotomy. I chose the former. I incised the uterus (longitudinally, and commencing as near the fundus as possible) while still in the abdominal cavity, and extracted the child by the feet. The incision was through the placental site, and hæmorrhage very free for a few seconds, but was completely controlled by Dr. Smyly, who slipped both his hands down on to the cervix the moment the emptying of the uterus permitted of its being lifted out through the abdominal incision. The uterine wound, which was 6 ins. long, was begun with a scalpel and completed with scissors, and from the time of its commencement till the child was extracted was not more than 90 seconds. The wound in the uterus was closed with interrupted silkworm gut sutures passed down to but not including the decidua. The patient made a good recovery, was up on the twenty-eighth day after the operation, having nursed her infant from the second day after her delivery. Later I measured the patient's true conjugate with Skutsch's pelvimeter, and found it to be 6 centimetres only. It is difficult to understand how a woman with such a limited conjugate can have brought forth living children *per vias naturales*, except on the assumption that she did not go to "term" on these occasions and that the children were small. The child I extracted was a female weighing 9 lbs. I do not approve of craniotomy if the child be ascertained to be alive, and I believe it to be no whit less dangerous for the mother than Cæsarean section in either im-

mediate or ultimate consequences, while the child is sacrificed. Jardine (Glasgow) agrees with me on this point. I do not think the child could have been delivered alive in this case by the performance of symphysiotomy, and, even so, I prefer Cæsarean section to that operation. In favour of this opinion I may quote Charles Washburn (Boston), and Everke (*Wien Med. Woch.*, No. 51, 1898). Charles (in *L'Obstetrique*) says:—"Symphysiotomy is not less dangerous, as is commonly supposed, than Cæsarean section." Everke calls the suture of the uterine wound the "essential" feature of the operation. I agree with him, and advocate three sets of sutures—fine silk (interrupted) for the decidua and submucosa taken together, strong silk (interrupted) for the muscular coat taken alone, and a continuous fine cat-gut suture for the peritoneum, inserted so as to cover in completely all the silk sutures in the muscular coat. This is practically the method of Lebedeff and J. Veit, and, in my opinion, minimises friction due to respiration between anterior uterine and parietal or visceral peritoneum, thereby lessening possibilities of adhesion. I also advocate Marcey's manœuvre of drawing down the omentum over the incision as a good one—for adhesion of the uterus to the omentum would not be so undesirable, in the light of a subsequent pregnancy, as one of the uterus either to the abdominal wall or to intestine. I think Schultze's method of artificial respiration the best for new born infants, and I have never had any bad results, even after employing the method for upwards of two hours.

CASES OF WHITE SWELLING OF THE KNEE. (a)

By A. B. JUDSON, M.D.

DR. A. B. JUDSON, in introducing these cases remarked that with the scientific progress of the day great changes were taking place in our knowledge of disease. Although pathology took the precedence in medical studies she was a fickle divinity. We learned, but with the prospect of having to unlearn, and the all-wise, unwise public sensed this, and, when in dire straits, went doubtfully away, "trembling, hoping, lingering, flying," to fanes where the divinities were not only fickle, but meretricious. In white swelling of the knee, however, it was sufficiently established the use of the inflamed joint aggravated and prolonged the disease. Arrest of motion and cessation of weight-bearing necessarily followed as a part of rational treatment. He described apparatus, and presented the following patients.

Case I.—Seen in September, 1898. A girl, æt. 6½. Early diagnosis. No pain. Slight muscular atrophy and swelling of the knee. Flexion 20 degs. to 170 degs. An asymmetrical gait had been noticed for about five weeks. When told that a child was threatened with Pott's disease Dr. Taylor said: "The house is on fire or it isn't on fire." In the present case the occurrence of signs which, though slight, were well defined, established the diagnosis of osteitis. An ischiatic crutch for the protection of the limb from the weight of the body was applied. If resolution did not follow in a few weeks a fixative brace would be added.

Case II.—November, 1897. Boy, æt. 4. Duration of disease one year. Flexion 20 degs. to 125 degs. Ischiatic crutch was applied, and three months' later a fixative brace. Pott's disease appeared in the lumbar region and a spinal brace was applied in December, 1898. Knee at 2 degs. or practically straight. Prognosis favourable. Apparatus worn with ease and convenience.

Case III.—January, 1897. Girl, æt. 5. Duration, three years. Subluxation was present. Severe pain; flexion 55 degs. to 125 degs. Apparatus applied, March, 1898. Abscess appeared, but had been absorbed. Subluxation persists, but the femur is super-imposed so far over the tibia, that the stability of the limb would not be impaired. Knee is at 6 degs. Prognosis good.

Case IV.—August, 1895. Boy, one year, nine months. Duration, a few weeks. Knee at 90 degs. Swelling and severe pain. A year later destruction of the bone was

(a) Section on Orthopedic Surgery, New York Academy of Medicine, October 20th, 1899.

far advanced with sinuses on all sides of the knee. Subluxation. The fixative brace was applied, with relief of pain, and six months later the addition of the ischiatic crutch restored the child to activity. Prognosis good. Sinuses closing. Knee at 10 degs.

Dr. W. R. Townsend said that thorough surgery would do a good deal for the patient. The knee was septic, and although children tolerated pus better than adults, some day a general sepsis would appear and the child would lose its life.

Dr. Judson said that long and frequent absences from the dispensary had marked the history and had delayed recovery. It was probable that other advice had been freely sought. If the general condition was good at the time it might have been said either that mechanical treatment should proceed or that an operation would be well borne and would hasten recovery. If the condition had been bad, as it was at times in the extreme, an operation might have been urged to save life or postponed on the ground that the chance of recovery was too small. The patient had escaped the loss of bone by operation and the result would be recovery with greater straightness, length, and stability of limb than could be hoped for after an operation.

Case V.—January, 1889. Girl, *æt.* 3 years 7 months. Duration six months. Marked flexion. Fixative brace and ischiatic crutch applied. Flexion entirely reduced. Three abscesses appeared and in due time the resulting sinuses cicatrised. In October, 1894, motion was between hyperextension, 5 deg., and flexion, 30 degs., and treatment was suspended. Four years later flexion was found to have returned with motion 28 degs. to 48 degs. No symptoms. Fixative brace re-applied with reduction to 10 degs., with prospect of complete reduction. When the bones were mature their particular surfaces would have adapted themselves to each other so that the femur would rest securely on the tibia in the straight position.

Case VI.—Feb. 1896. Girl, *æt.* 10. Duration, three years. Knee fixed at 35 degs. after excision. Fixative brace applied. Flexion had been reduced to 20 degs., but had relapsed to 30 degs. from a failure to inspire the patient and her friends with enough confidence in the usefulness of mechanical means to lead to the necessary attention to the details of treatment.

Case VII.—Aug. 1895. Girl, *æt.* 3. Flexion at 22 degs. after operation on the bone. Fixative brace applied. Flexion entirely reduced. Prognosis good.

Case VIII.—January, 1893. Boy, *æt.* 7 years 6 months. Duration 18 months. Previous treatment by a splint protecting the limb from the weight of the body and a plaster of Paris dressing. Fixative brace and ischiatic crutch applied. Patient was presented to the Orthopaedic Section, April 20th, 1894. Crutch removed September, 1896, and brace January, 1897. Flexion 8 degs. to 75 degs., with no defect in his ordinary gait.

Dr. Townsend said that synovitis was present with effusion, and that he would continue to give support as absorption, which was desirable, would be doubtful if the boy was permitted to run about.

Dr. G. B. Elliott said that this case of chronic hydrops presented quite as high a degree of atrophy as those in which the bone was unquestionably involved.

Dr. Judson said that the presence of synovitic effusion had been early recognised, but had not reversed the diagnosis of osteitis.

Dr. Elliott said that the other patients also presented a high degree of atrophy above and below the joint. The merest tyro was familiar with the sudden atrophy of developing tuberculous joint disease, the cause of which was still far from being demonstrated. How could we differentiate atrophy due to disease from that due to bone disease? Atrophy in the great number of doubtful cases commended itself to us as a puzzling sign, whose many expressions could not as yet be interpreted.

Case IX.—March, 1891. Boy, *æt.* 14. Duration since infancy. Swelling and limitation of motion. Flexion 25 degs. to 55 degs. Two years after application of the fixative brace the knee was straight, and 18 months later hyperextended 10 degs. Treatment was suspended

January, 1896. Almost perfect ability in walking. Flexion 0 degs. to 20 degs.

Case X.—February, 1885. Boy, *æt.* 8. Duration four years. Marked subluxation. Flexion 30 degs. to 80 degs. Sinuses. Thomas's splint for protection, and a fixative brace, March, 1885. Presented to the Section, March 19th, 1886. An ischiatic crutch in place of Thomas's splint, January, 1887. Hyperextended 2 degs. Sinuses closed. Ischiatic crutch removed March, 1890, and fixative brace was occasionally worn until January, 1895. On presentation flexion was 25 degs., a result due in large measure to failure to secure due attention to treatment at home.

Dr. Townsend said that although there was considerable deformity there was a useful limb. The absence of motion was an advantage as, with motion, he would not walk so well.

Dr. Judson said that gradual, painless, and complete reduction of flexion should have been well within the power of a simple lever such as the fixative brace, and the ability of the limb to uphold the body would have been thereby increased. He did not object to the presence of motion if the knee were capable of full extension. In the absence of motion, ability to walk well after recovery would be increased by raising the shoe of the unaffected side by adding to its sole and reducing the thickness of the sole on the affected side.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, NOVEMBER 24TH, 1899.

The President, Dr. A. V. MACAN in the Chair.

Dr. PUEFOY exhibited five myomatous uteri removed by abdominal section recently in the Rotunda Hospital.

Dr. KIDD exhibited a myomatous uterus removed by abdominal section.

Dr. ALFRED SMITH exhibited seven fibro-myomatous uteri removed by retro-peritoneal hysterectomy. In one double salpingo-oophorectomy had been performed previously in the hope that the hæmorrhage would be arrested. The operation was attended with more than ordinary difficulty owing to the fact that bad adhesions had formed. The tumour, though small, had caused great loss of blood, and complete ablation of the ovaries had failed to arrest hæmorrhage.

Dr. GLENN'S SPECIMEN—EXCISION OF COCCYX FOR DISLOCATION CAUSING SEVERE COCCYGOPTIA OF MANY YEARS' STANDING.

Dr. KIDD related three such cases. In one of his cases union was so complete that the cicatrix could not be seen. In two of the cases the pain was completely relieved.

Dr. GLENN, in reply, said he now thought the crepitus was a true crepitus, due to the rubbing together of the ends of the bone. It was only three weeks since the operation, and the pain had diminished, but had not completely disappeared.

A CASE OF CÆSAREAN SECTION.

Dr. G. COLE-BAKER read a paper on a case of Cæsarean section, which will be found under "Clinical Records."

Dr. KIDD said the case he had reported differed in many respects from Dr. Cole-Baker's. His own operation was performed in a condition where labour was obstructed by a tumour which filled the lower part of the pelvis, while Dr. Baker had operated for deformity of the conjugate diameter. It was a common misfortune to come down on the placenta, and, of course, if the operator, in his hurry to gain entrance, incised the placenta, it added to the danger of losing the mother and child. The question of putting ligatures through the mucous membrane of the uterus was important. Where a local discharge, which had become septic, afterwards occurred, he thought the passage of these sutures

into the cavity of the uterus would be an indirect means to allow this discharge to get between the walls.

The PRESIDENT said that where there had been a long labour the danger of Caesarean section was very great—in fact, the operation was at times almost contra-indicated. Symphysiotomy was still permissible long after the period for Caesarean section had gone by. Dr. Baker was to be congratulated on having such a successful result after a twenty-four hours' labour. He looked on the elastic ligature as the great cause of asphyxia. With regard to suturing the uterus, he would use ordinary boiled silk, and rather than lose two seconds over the operation, would include the mucous membrane.

Dr. BAKER, in reply, said he failed to see that the suture tracts passing through the decidua could in any way conduce more to absorption from the uterus than in the case of any other mucous membrane. The asphyxia of the child was not due to pressure, as none was applied, either with the elastic ligature or by the assistant, until the child had been removed.

The PRESIDENT then read his address on "The Significance of Pain in Gynecology."

The Section then adjourned.

SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, DECEMBER 1ST, 1899.

The President, Professor A. C. O'SULLIVAN, M.D., in the Chair.

EXHIBITS.

SUICIDAL WOUND OF THROAT WHICH SEVERED THE RIGHT COMMON CAROTID ARTERY AND PNEUMOGASTRIC NERVE, CAUSING IMMEDIATE DEATH.

Mr. HENRY GRAY CROLY furnished the following notes on above case:—J. H., *et. 34*, was admitted into the City of Dublin Hospital on September 1st, 1899, suffering from a hard fungating growth projecting through the orifice of the prepuce. The patient evidently had a natural phimosis. The glands in the groin were much enlarged. No direct history of syphilis could be obtained. The patient was sent to me as a probable case of epithelioma. The prepuce was slit and the foreskin removed, and the growth shaved off the glans penis. Mercury, with iodide of potassium, was administered. The glands in the groin got much smaller, and were subsequently excised. The patient, though dissatisfied at the slowness of his case, never showed any suicidal symptoms. On November 4th, the man asked permission to go into the lavatory, and objected to the bedpan. He went to the bathroom after his dinner, locked and bolted the door, and was found lying dead, with a razor in his right hand. The floor was covered with arterial blood. On examination the right carotid was found divided, and its ends retracted about 1½ ins. The right pneumogastric nerve was also severed, and the cartilages of the larynx severed in more than one place. The penis was removed post-mortem, and on section was found to be normal.

Dr. R. CHARLES B. MAUNSELL showed a varicose aneurysm which he had excised from the right forearm of a man, *et. 42*, who had received a punctured wound, from a broken bottle, over the line of the radial artery about 2 ins. above the wrist-joint. Pulsation and a sharp thrill and buzzing sound were well marked before removal. The aneurysm had grown to the size of a walnut in a fortnight.

Mr. M'ARDLE demonstrated the case of a boy with a peculiar form of ectopia vesicæ (artificial marsupialisation); also the bones of forearm from a case of compound fracture, and a collection of vesical calculi.

The PRESIDENT (Professor A. C. O'Sullivan) gave an address on the mode of action and production of Antitoxin.

MALFORMATION OF KIDNEY.

Dr. EARL demonstrated this specimen, observing that the right kidney and both suprarenal capsules were normal as to position and vascular supply. The left kidney lay on the brim of the pelvis; it was tightly held

down by the peritoneum, and partly covered by the sigmoid flexure of the colon. It was somewhat smaller than the right, convex on its anterior surface, slightly concave on its posterior surface. The inner margin was more curved than the outer. The left ureter was 5½ ins. long, that on the right side being 10½ ins. The hilum was on the anterior surface. It consisted of a deep depression near the lower end of the kidney, which was continued upwards into two shallow depressions about ½ in. apart, lying parallel to each other and to the long axis of the organ. Each of these was about 2 ins. long. The ureter divided near the kidney into two branches, one of which entered at the lower part of the hilum, while the other again divided into branches for the longitudinal parts. The artery came off ½ in. above the bifurcation of the aorta, and divided into three branches, two of which entered the kidney at its inner margin near the upper end, while the third ran behind the kidney, giving a branch to its posterior surface. It finally turned round the outer border, and, grooving the anterior surface, terminated in the lower part of the hilum. The vein entered the vena cava in the normal position. A little above the kidney it divided into two branches, which lie in grooves on the anterior surface, and having given branches to the longitudinal parts of the hilum, terminate in its lower part.

RECENT INVESTIGATIONS IN THE BACTERIOLOGY OF BERI-BERI.

Dr. PERCY GERRARD's paper on this subject was communicated by Dr. A. R. PARSONS.

The PRESIDENT did not see, however, why, if an attack of eysipelas would cure sarooma, the streptococcus should not cure beri-beri without a specific action.

Dr. J. A. SCOTT said that during the epidemic of 1894 in the Richmond Asylum, Dublin, he made, with Dr. Rambaut, some investigations into the condition of the blood in this disease. A number of attempted cultures remained absolutely sterile. In other cases, however, colonies grew, and these were subsequently separated. Some of the patients he observed were always sure finds as regards cultures, whereas other cases, equally as bad, were always sterile.

Dr. E. J. McWEENEY said that the amount of material Dr. Gerrard had operated on, a loopful of blood, was so small that, if the cocci had really been in the blood, it seemed to him there ought to have been no difficulty in demonstrating them microscopically. With regard to the improvement of the patients under anti-streptococcic serum being co-ordinated with a growth of a yellow colour obtained from the blood, he thought there could be no connection, because the streptococcus did not produce a yellow colour. The injection of the serum, however, might have produced, as the President had hinted, a general phagocytosis of a non-specific character, but that state of affairs could not denote any connection between streptococci and beri-beri. There was such an extreme difficulty in sterilising the skin that in his own work he would pay no attention to a result got from a drop of blood that had been in contact with the skin. The method he employed successfully was to extract ccs. of blood from one of the veins in the arm with a sterilised hypodermic or antitoxin syringe. So few were the micro-organisms in even violent septicæmia that unless they extracted a good deal of blood they would not find any micro-organisms at all. It was with these precautions that he had succeeded in getting the diplococcus pneumoniae in a case of ulcerative endocarditis coming on after acute pneumonia.

Dr. CONOLLY NORMAN, referring to the micro-organisms described by Pechelharing and Winckler, said that they found them in every patient's blood; but they also found them in the blood of persons in Atjeh who had not beri-beri, and similar cocci were also found in the air of that place. Dr. Norman showed illustrations of cocci found by other observers which were very dissimilar to those of Pechelharing, but he (Dr. Norman) pointed out that these cocci were obtained from the dead body, and he, therefore, considered them of little value. Pechelharing's and Winckler's results were disputed by other investigators, among whom was Scheube, who said

that their observations were made on dirt, and that most of the animals which they had injected experimentally had died of septic poisoning. Glogner found parasites in the spleen resembling those of malaria, and on that fact had founded his theory, which had got a few adherents, that beri-beri was identical with malaria. At Tuscaloosa, in the State of Alabama, cocci were found in the blood of beri-beri patients, but they were not described in detail. One of the peculiarities of the disease which Dr. Gerrard had remarked, and which he also had noticed, was that patients frequently got relapses, and often died rather suddenly after apparently getting quite well. In a recent monograph on the subject Grimm laid it down that beri-beri always commenced with slight initial fever.

Dr. KNOTT pointed out that Dr. Gerrard's cases commenced with fever and diarrhoea, and that one of his cases was engaged in mining operations. He remembered reading some years ago the theory that beri-beri was produced by the same parasite as produced Egyptian chlorosis.

Dr. PARSONS, in reply, said that most of the points which had been raised had been already touched upon by Dr. Gerrard in his paper. Bearing in mind Dr. Scott's notes, it was interesting to observe that several of Dr. Gerrard's cover-glass preparations had shown distinctly diplococci, and in many cases tetra-cocci. Most of Dr. Gerrard's patients were miners, and this seemed to point to the poison being in the earth. In a few cases the *Anchylostomum duodenale* was found.

PRIMARY SARCOMA OF THE LIP.

Dr. CHARLES B. MAUNSELL read notes of a case of a married lady, *et.* 32, from whose lower lip he had removed a small prominent tumour. She was suffering at the same time from well-marked chloroasma uterinum. On examination the tumour was found to be a spindle-celled sarcoma. Dr. Maunsell drew attention to the rarity of sarcoma of the lip, and stated that so far he could find no reference to it in English works, but he had found a short notice of two cases by Vidal and Luttegast in "Duplay and Reclus' Surgery." Dr. Maunsell showed sections prepared by Dr. H. C. Earl.

Dr. E. J. McWENNEY said that about a week ago a specimen was given to him in hospital from the lower lip of a child, aged ten years. The portion bore a growth, slightly ulcerated, about the size of a pea, roundish in outline, and suspected by the surgeon who had removed it to be a sarcoma. On section it proved to be a mixture of sarcomatous tissue, with dilated lymphatics and a considerable number of minute newly-formed capillaries. He reported it as being a lymphangio-sarcoma.

Dr. MAUNSELL, in reply to the President, said that the tumour was not pigmented.

The Section then adjourned.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

CLINICAL MEETING HELD DECEMBER 20TH.

Mr. A. G. MILLER, President, in the Chair.

Dr. ALEXANDER BRUCE showed (1) a woman suffering from progressive muscular atrophy of the peroneal-forearm (Charcot-Marie) type. There was complete foot-drop following paralysis and atrophy of the peroneal muscles, the muscles of the forearm and hand were also affected, giving rise to claw hand and ulnar flexion. Sensation was intact, but spinal curvature and difficulty in articulation had lately appeared owing to paralysis of the muscles of the back, lips, and tongue. There was also some mental weakness. The lesion was believed to be a parenchymatous neuritis with affection of the posterior columns of the cord. The case differed from the ordinary Charcot-Marie paralysis in the age of onset, 50, in the involvement of the muscles of the trunk, and in the absence of an hereditary history.

2. A case of infantile paralysis affecting the muscles of the hand. The left hand was smaller than the right, all the intrinsic muscles were paralysed, and sensation

was unimpaired. The lesion here was a circumscribed poliomyelitis at the level of the first dorsal segment.

3. A case of senile chorea of eight years' duration in a man of 50. There was neither mental impairment nor hereditary history, so that the condition could not be regarded as Huntington's chorea.

4. A case of paralytic clonus multiplex. The lower limbs, especially the thighs, were most affected. The movements were more or less symmetrical, consisting of sudden jerkings of muscles or groups of muscles. They were most marked when the patient was at rest or when he was excited; they diminished while walking and were abolished during sleep. There was increased mechanical irritability of all the muscles and exaggeration of the knee-jerks. The condition was probably functional.

5. A case of injury to the lumbo-sacral roots. The patient fell and struck the left buttock nine months ago. Immediately thereafter he lost the power in the left leg, and three weeks later the limb became anæsthetic. Four months ago the right foot also became paralysed. The anæsthetic area in the left leg exactly followed the outline of the areas of the 4th and 5th lumbar, and the 1st sacral nerve roots. The paralysis of the right foot was due to a superadded alcoholic neuritis.

Dr. NORMAN WALKER showed (1) two cases of ichthyosis in the same family, (2) a case of acne necrotica, and (3) cases of lupus and favus, which had markedly improved under treatment with X-rays.

Dr. ALLAN JAMIESON showed a case of papulo-anæsthetic leprosy.

Dr. JAMES showed (1) a child with post-hemiplegic athetosis, and (2) a case of Jacksonian epilepsy with weakness and increased reflexes on the right side. The illness began with general convulsions four years previously.

Mr. STILES showed (1) an infant after operation for acute ileo-cæcal intussusception, (2) a boy after Mikulicz's operation for disease of the posterior tarsus; (3) a patient who suffered from acute thyroid cachexia after excision of suppurating goitre. Forty-eight hours after the operation the patient became very sullen and refused to reply to questions. She became jaundiced, complained of general aching, and then twitching of the muscles set in, the toes becoming pointed, and the calves rigid. All the symptoms disappeared within twenty-four hours of the administration of thyroid tablets. (4) A patient after excision of a large lymphoma of the neck. (5) Patient after avulsion of the entire scalp, in whom repeated grafting had been tried without benefit.

Dr. F. D. BOYD showed (1) a case with some of the signs of syringo-myelia. There was atrophy and paralysis of the muscles of the hands and shoulder-girdle, and complete loss of temperature sense in the palms of the hands. There was, further, contraction of the visual fields, anosmia, paralysis of the right half of the palate, and loss of power of adduction of the right vocal cord. (2) A case of alcoholic neuritis with paralysis of both facial nerves as well as slight paresis of the motor division of both fifth nerves. (3) A case of peripheral neuritis of pregnancy.

Dr. GIBSON showed a case of pseudo-bulbar paralysis. The following specimens were also shown: by Dr. A. C. Sym, larynx and tongue from a case of angina Ludovici; by Mr. Cotterill, tumour of the brain, urethral calculi; by Dr. Gibson, specimen of myomalacia cordis; by Dr. Purvis, exostosis of the femur.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, December 24th, 1899.

SKIAGRAPY AND FRACTURES.

At the last meeting of the Société de Chirurgie, M. Tuffier remarked that for the last eighteen months he examined with the radiograph all the fractures

observed in his ward, at first before reduction was attempted, and then after the reduction. From the several documents obtained, he was struck with the frequency of the irreducibility of fractures, in spite of the employ of apparatus of contention to which had been given entire confidence. More than once when he had thought the co-operation of the fragments was perfect, the radiograph showed that it was far from being the case. However, he should add, that definite result proved happily that it was not always necessary to obtain perfect reduction in order to have satisfactory function of the limb.

COXALGIA.

M. Meirard, recurring to the subject of the treatment of coxalgia, said that resection of the hip had been abandoned by many surgeons, because in certain countries an unjustifiable abuse was made of the operation. One of his colleagues considered that the persistence of pain constituted an indication for resection, but such was not his opinion, for he had always found that absolute rest caused the pain to cease. As to the treatment of abscesses he employed in 200 cases injections of thymol and camphor, which were neither toxic nor painful, and 1 per cent. cases were cured under their influence.

In twenty-two patients who had remained refractory to this treatment he resected the articulation and all of them got well.

As to the orthopaedic results of that operation, they varied evidently with the extent of the lesion. But in a general way each time the cure was obtained in a few months without necessitating further operations, the length and attitude of the limb were very satisfactory.

DIURETIC ACTION OF CALOMEL.

According to Dr. Bourgeon calomel acts as a diuretic in heart affections accompanied by oedema. It produces progressively increasing diuresis, but during its administration only. The quantity of urine varied from a pint to two quarts or more. From four to eight grains are given daily for from three to five days, but the kidney should be watched as the calomel should be suspended on the approach of albumine.

SUDDEN DEATH IN INFANTS.

The sudden death of children from a few days to a few months old is an accident which but too frequently provokes unjust condemnations, or, at least, unworthy suspicions on the doctors or the nurses who have had charge of them. Habitually, the accident happens thus: An infant appearing to be in perfect health dies suddenly in its bed, or on the knees of the nurse. The autopsy reveals no cause which might explain the sad affair except a simple hypertrophy more or less considerable of the thymus gland. Sometimes, however, the death is preceded by a very short period of dyspnoea. M. Berthold, who has written on the subject, cites the case of a nurse who was accused of killing the child confided to her; fortunately, the post-mortem examination showed that the thymus gland was considerably enlarged. Besides hypertrophy of the above gland there are, according to the same author, two other kinds of sudden death in children—spasm of the glottis and brusque extension of the head backwards. This latter accident is mainly observed in rickety children, in whom the head is relatively very large and increased in weight and who are in-

capable from weakness of bringing back the head to the normal position without the help of another person.

IMPETIGO.

The following I have found most useful in this affection:

Salicylic acid, 3ss.
Lanoline, 3iiss.
Oxide of zinc, } ʒvj.
Starch,

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, December 23rd, 1899.

At the last meeting of the Medical Society Hr. Rothschild showed a kidney removed by

NEPHRECTOMY

from a young woman of 27, in whom the operation was perfectly successful, although the excretion of the urea was only one half of the normal. The patient, although no tuberculosis was present, had suffered for six years with increased desire to micturate, pain on micturition, fever. She was confined to bed, but up to lately had been only treated by a "quack," who had washed out the bladder. On May 4th, 1898, she was admitted into hospital in a pitiable condition. She was constantly wet, day and night; she could only press out a few drops of purulent urine at a time. Her bladder was contracted and only held 10 ccm.; the bladder walls were smooth. The right kidney could be felt at the umbilical level, slightly enlarged. By mechanical dilatation of the bladder enough improvement was effected to allow of the patient's return home. In September of the present year she was re-admitted with the symptoms as bad as before. Both kidneys could be felt. Distension and washing out of the bladder were again carried out until October 24th, when a cystoscopic examination was made under continuous irrigation. The left ureteral opening normal, on the right side pain. The urea had fallen to 1.3 per cent., but there were no uræmic symptoms. The patient, on account of the pain, requested operation on the wandering kidney—the right. On operation there was found to be total pyonephrosis on the right side, the kidney containing no functioning substance whatever. The patient made a good recovery, and the quantity of excreted urea was increasing.

At the same meeting Hr. Lexer showed a man, æt. 41, from whom a

MESENTERIC TUMOUR

had been removed in v. Bergmann's Klinik. The patient took ill of abdominal pain in April, 1899, and a tumour was discovered. In October he was admitted into hospital, the abdomen being then very prominent. In the middle of the abdomen was a hard nodular tumour the size of a child's head. On relaxation of the abdominal walls under an anæsthetic it was found to be movable. The size and hardness of the tumour, its great mobility, its position in the middle of the abdomen, and the absence of bowel symptoms pointed to mesenteric tumour. On opening the abdomen a loop of intestine was found running over the tumour. The chief mass of the tumour was attached by a pedicle to the vertebral column. The pedicle was the radix mesenterii. This was ligatured and severed without

bleeding. Resection of intestine was performed, with lateral anastomosis of the ends by suture. Afterwards it was found that over 6 ft. of intestine had been removed at the resection. Recovery was uninterrupted. In three weeks the patient could get up, and he was at that time (November 20th) quite well. Of the 29 cases of mesenteric tumour hitherto reported, 15 had died, 14 recovered. The causes of the unfavourable course were shock hæmorrhage, peritonitis, when badly nourished ends of intestine had been left, when not enough had been resected or when lateral anastomosis had not been made. The tumour was a hard fibroma with myomatous parts (weight $4\frac{1}{2}$ lbs.).

IODIDES OF SODIUM AND POTASSIUM IN HÆMORRHAGES.

In the *Arch. f. Kl. Med.*, 63 to 66, Hr. A. Chelmonski recommends the use of iodide in hæmorrhages with increased blood pressure. His recommendation is based on several cases observed personally. Preference is given to the soda salt, as it reduces the blood pressure at once, whilst the potassium salt first raises it and then slows the cardiac beat. The blood pressure sinks only after one to two hours, and the cardiac activity increases. The drugs were given in doses of 0.2 to 0.3 grm. twice daily in half a glass of milk. The writer saw a brilliant result in a case of hæmoptysis in which all other remedies that had been tried had failed. A good result was also obtained in a case of excessive epistaxis occurring in a patient, æt. 39, with aneurysm of the aorta. After taking two doses only, the hæmorrhage ceased and did not recur. The potassium salt was given in this case. In both cases the blood pressure had been high.

ASEPSIS AND ANTISEPSIS IN GYNÆCOLOGY AND OBSTETRICS.

Prof. Olshausen discusses the subject in a late number of the *Berl. klin. Wochensh.* (45.99).

The high position held by Prof. Olshausen as first professor of obstetrics and gynæcology in Berlin, lends an added interest to the subject. He claims that asepticism and anti-septicism stand on a different footing in his department of medicine to that they occupy in general surgery. This is due to the abundant flora of the vagina and to the very serious consequences of septicity occurring in the genital tract. The dangers of the vaginal flora should not be underestimated, and the more so as the vaginal tube offers obstacles to suitable disinfection. A sterile field of operation here is scarcely possible or at most very transient. Clinical experience would point to a weakening of the virus of vaginal germs. The fact known for years that gonococci that produced no results before labour, after labour forced their way through the tubes and set up peritonitis, was most naturally explained on the hypothesis that changes suddenly taking place in the vagina during the puerperal state, produced such a nutrient soil for them as renewed their original virulence. The conditions are similar in regard to the other germs, and all this leads to the great necessity of avoiding wound surfaces on the one hand and of infective material on the other.

With regard to obstetric operations he has made out a danger scale in the following order. The least dangerous operations are forceps extractions from the outlet, especially in multiparæ. Next come pertoration and subsequent cranioclasia, and internal version. Then comes high forceps extraction, mostly associated with bruising and laceration of the soft parts. Still more

dangerous is artificial premature labour. The most dangerous of all operations, however, is the manual separation of the placenta. For this operation the Professor advises the use of Döderlein's india-rubber glove. For extraction at the outlet disinfection of the external genitals is enough; for the high operation the vagina is also disinfected in the University Klinik with carbolic acid or lysol, but he is of opinion that this disinfection has its disadvantages as well as advantages. The cases entailing acute danger are such as demand speedy operative delivery, or are complicated with hæmorrhages; in gynæcology they are those of internal hæmorrhage from ruptured ectopic gestation. In such cases the danger arising from the state of the patient is to be weighed against that of a changed and shortened antiseptic preparation. The beginner is likely to underestimate the latter, and to the prejudice of his patient. In such cases when time does not allow for boiling (and sublimate is not suitable for instruments), these should all be thoroughly disinfected by well rubbing with alcohol. This can also be used for the hands after thorough use of soap and water.

In the case of rupture of an impregnated tube, the danger is so great as to far outweigh that of infection. Objective disinfection in such cases should be limited to soaping of the body, shaving off the upper layer of epidermis with the razor, and quick washing with alcohol, and in extreme cases the latter only should be waited for. A deep narcosis should never be waited for, as patients are unconscious a few minutes before death from hæmorrhage. Hands and instruments should be quickly washed with alcohol. Pressure forceps are rarely required, and the abdomen can be open in less than ten minutes after operation has been decided on. Technique should not be forced into the background by disinfection, for it is a fact that danger of infection increases with length of operation, and, it is too much, disinfection that itself lengthens the operation.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, December 23rd, 1899.

ESOPHAGEAL CICATRIX.

At the *Gesellschaft der Aerzte* Dörr showed a young girl in whom the oesophagus was totally denuded of mucous membrane for upwards of thirteen centimetres in its length as proved by the microscopic examination. In addition to this the circular and longitudinal muscular tissue was also absent.

The cause had been due to the girl swallowing nitric acid by accident. In the literature of the subject we have only eight cases recorded where total denudation has occurred, two of which ended fatally. This is not due to inflammation of the submucosa and exfoliation of the mucous membrane and tissue, otherwise the inflammatory process would have been much more extensive and must have reached the mediastinum, which was not so in the case shown; also the microscopic examination bore no testimony of such an inflammatory process. He compared the mechanical loss of tissue to that existing between uterus and placenta.

STRICTURE OF BOWEL

Schnitzler exhibited a female, æt. 27, who had

suffered for the previous three years with symptoms of stricture in the bowel. In October last he performed laparotomy, and found three different stenotic strictures in the small intestine, evidently tuberculous. He concluded the operation with inter-anastomosis, with perfect recovery. As in all other cases recorded, the results bore out the opinion that the increased peristaltic action caused the pain and not the stenosis, as the hypertrophied bowel was further strained by pressure and the dilatation increased. Schrötter remarked that the stenosis was not of the typical tuberculous character, as it is rarely the case that multiple tuberculous ulcers heal in the bowel. He would be inclined to characterise Schnitzler's multiple strictures as mechanical, due, probably, to some foreign body. Schnitzler repelled this assumption on the ground of a circular stenosis being rarely found from foreign bodies, while there was no symptom or evidence in the history of such a foreign body being present. As to the assertion of multiple tuberculous stenosis not healing he was able to bring forward evidence to the contrary with microscopic specimens.

"SPONDYLOSE RHIZOMÉLIQUE."

Schlesinger brought forward two patients under his care with a rigid condition of the spine. The first was a male, *æt.* 59, with the typical symptoms of Marie's "Spondylose Rhizomélisque." The pathological condition is described as a stiffening or hardening of the binding apparatus of the vertebræ, or possibly ankylosis of the articulations. The clinical history of the disease is described differently, and is often associated with other joint diseases, such as arthritis deformans, gonorrhœic arthritis, or even chronic articular rheumatism. The usual history is a progressive stiffening of the vertebræ advancing to the hip, shoulder, and costal joints. According to Schlesinger the disease often attacks the hands, feet, and other joints, and is usually preceded with great pain.

The second case was also a male, *æt.* 67, who had fallen fifteen years previously from a cart, in whom afterwards the stiffening gradually increased. In this case there was a distinct kyphosis in the cervical and upper part of the dorsal vertebræ with atrophy of the shoulder muscles. Schwartz remarked that he recently had an analogous case associated with pain where the nerve roots had been interfered with by changes in the bony structure of the vertebræ.

The Operating Theatres.

MIDDLESEX HOSPITAL.

SPLENECTOMY FOR RUPTURE.—MR. KELLOCK operated on a man, *æt.* 40, who had been run over by a hansom cab about three-quarters of an hour previously. On examination the patient was evidently suffering from loss of blood as the result of his injury; he was complaining of severe pain in the abdomen, chiefly referred to the left hypochondrium and to the back. The abdomen was very tender on manipulation and the walls rigidly contracted, rendering examination very difficult; there were no marks of injury or of bruise of the skin of the abdomen. There was no evidence of free fluid or gas in the peritoneal cavity, but the area of splenic dulness was increased. There were marks of other

injury to the left elbow and to the left knee (acute synovitis of the latter). Urine had been drawn off by a catheter and found normal. The man was anaesthetised and an incision 5 ins. long made in the left linea semilunaris. On opening the abdomen a fair quantity of dark-coloured blood escaped; on passing the hand to the splenic region it was at once discovered that the spleen was extensively lacerated. A short transverse incision was then made from the centre of the longitudinal one, and, the intestines being retracted towards the middle line, the injured organ was brought into view and blood was seen to be issuing from it. It was brought forward, the pedicle being held between the finger and thumb of the left hand; this last was next transfixed and ligatured in two portions with silk and the organ removed. It was found that this proceeding had arrested all the bleeding. On examining the place from which the spleen had been removed it was found that a small piece of the organ still remained attached to the peritoneum; this piece was also removed without difficulty. No extensive examination of the other abdominal organs was made; a large quantity of blood clot was removed from the peritoneal cavity by sponging, and the wound in the abdominal wall closed all in one layer with silk sutures. Mr. Kellock said that after such an accident the symptoms the man presented were fully typical of the condition which was subsequently found, and the fact that there was no external mark of injury on the abdominal wall did not preclude serious internal damage. The man was evidently suffering from internal hæmorrhage. He was cold, pale, and restless; the fact that the urine contained no blood negatived injury to the kidneys or to the bladder, the direction of the violence and the seat of the pain were against the liver being the source of the bleeding; there remained then the possibility of ruptured spleen, ruptured intestine, or bleeding from the mesentery or the omentum, but the fact that the area of splenic dulness was increased led him to make the incision in the situation best adapted to deal with that organ. When it was discovered that the spleen was the source of the hæmorrhage, and that it was extensively lacerated, no alternative was left but to remove it, in doing which no great difficulty was experienced. The isolated portion of the organ which was subsequently removed, had evidently been completely broken away from the spleen at the time of the accident. The source of the hæmorrhage having been discovered and dealt with, and the patient evidently feeling the effects of loss of blood rather severely, it was not, he said, thought advisable to make an extensive examination of the other abdominal organs on the chance of there being other injuries. The condition found in the peritoneum being quite an aseptic one no washing out was employed, the fluid blood and clot being removed by sponging, and as it was evident from the examination of the pedicle that the bleeding had been effectually controlled, the wound in the abdominal wall was completely closed without the use of a drainage tube. He pointed out that the operation of removal of the spleen was quite compatible with life, as had been proved not only by operations similar to the present one but also experimentally; moreover, removal of the organ was practically the only way of arresting the hæmorrhage which,

if left alone, must prove fatal. In the absence of other undiscovered injuries, the prognosis, as far as the man's life was concerned, was, he thought, good.

On examination of the organ removed it was found very extensively lacerated through its whole thickness, and one small portion about the size of a walnut had been completely torn off from the rest of it.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, [DECEMBER 27, 1899.

THE UBIQUITOUS MICROBE.

OF recent years bacteria have assumed a position of first importance in the researches of scientific medicine. Great, however, as the discoveries in that direction have undoubtedly been, it is nevertheless fairly certain that as yet hardly more than the fringe of the subject has been grasped. The saving in human suffering and in human life has already been enormous, and it seems probable that when the sanitary millennium descends upon this world of ours its advent will be to a great extent due to our knowledge of the natural history of the ubiquitous microbe. It argues a great deal for the reasoning intellect of mankind that not a few of the practical problems both of preventive and curative medicine were successfully handled before the discovery of specific micro-organisms as a *causa causans* of diseased processes. Indeed, so far as that goes, we are still in the dark as to the pathogenic entities answerable for such strongly marked infections as small-pox, measles, and whooping-cough. Even when a morbid reaction is traced to particular bacteria the difficulties of the task for the medical attendant are by no means over. He may be able to attack the symptomatic inflammation directly with germicides if it be situated on the surface of the body, as in the case of erysipelas. Or he may combine external and internal reme-

dies, as in diphtheria, in which the throat lesion is treated with antiseptics while the blood is charged with antitoxin. Into the wide question of serum-therapy, with its vast field of potentialities, we do not propose here to enter. There are a few points in connection with local or surface infections of sufficient interest to warrant discussion, even when of the brief and general nature entailed by the limits of an article such as the present. The main difficulty in the application of germicides appears to be physical, that is to say, the mischief-working micro-organisms are effectually shielded from harm by the cells of the tissues and morbid excretions in which they flourish. In this way the utility of sprays and powders and other vehicles of antiseptic administration has fallen far short of what was anticipated in theory. What is wanted and what was earnestly sought after by Lister in his earlier researches was a penetrating antiseptic, and it was no doubt greatly owing to its detergent qualities that carbolic acid became the favourite agent adopted by that illustrious surgeon. The ideal antiseptic, however, has still to be found, notwithstanding that many excellent materials are now available in every branch of preventive and curative medicine. Incidentally, a flood of light has gradually been thrown on various therapeutic measures. Perhaps one of the most interesting recent observations is the modern treatment of corneal ulcers, which are now robbed of much of their danger. It was found that touching the ulcer freely with pure carbolic acid constituted a great advance on previous methods, and nitric acid used in the same way has proved successful in other hands. Still more certain results have followed the application of the actual cautery, heroic though the plan may seem. It is hardly open to doubt that the ulcer is caused by a microbial invasion, and that the bacteria are directly destroyed by the heat. The action is comparable of the cautery iron upon lupus patches on the skin, although in the latter situation the further action of phagocytosis is excited, a process that would occur only to a limited extent in a structure that under ordinary circumstances is non-vascular. Another great advance in the rational antiseptic treatment of eye diseases had been made by the abandonment of nitrate of silver in favour of silver salts of greater penetrative power, of which protargol may be taken as a type. Purulent ophthalmia is due to the gonococcus, an organism that invades the deeper layers of the mucous and submucous coats of the conjunctiva, where it is found very commonly not only in an extra-cellular but also in an intra-cellular habitat. Nitrate of silver rubbed into a mucous membrane at once coagulated the surface albumin, but failed to penetrate into the deeper tissues. Indeed much of its undoubtedly beneficial effect may safely be ascribed to subsequent phagocytosis. The newer salts, on the contrary, do not coagulate albumin; they possess greater powers of penetration and do not cause pain. These two instances of improved methods of controlling local germicide action are of value as types of what may be hoped for in a near future in

other directions. The war against the bacteria is likely to last for many generations, although there is no room to question that in the long run the intelligence of man will secure him the victory. To put to rout the single disease, influenza, would be to confer a vast benefit upon the human race, and it must be remembered that influenza is one of many foes that walk in darkness.

THE FEMALE NURSE IN THE ARMY.

THE question of the employment of female trained nurses in the field is just now very much the order of the day, and as the army medical authorities of the United States were confronted with the problem during the war against Spain, their conclusions are not without interest. Colonel Dallas Bache, Assistant Surgeon-General, recently published in the *Journal of the Military Service Institution of the United States* an instructive paper, in which he discusses the make-up of the hospital corps in times of peace. This organisation, though it may be trusted to provide adequately for the care of the sick under ordinary circumstances is, of course, quite insufficient to meet the enormously increased strain put upon the service in time of war. Difficulties at once arose, it became necessary to provide additional attendants, and, as might be supposed, the woman nurse came to the front. Colonel Bache admits the failure of the Medical Department to respond to the demands made upon it with such suddenness, and attributes it, or part of it, to the advent of the female nurse. The Army Medical Department were obliged to accept the services of a number of female nurses for the simple reason that no other means were available of obtaining trained persons to assist in attending to the wounded, trained male nurses being as rare as they are precious. Altogether upwards of 1,150 nurses found their way to the field of war, and of these fourteen died of exposure or infection. The Colonel is reluctantly constrained to admit that, in the absence of trained men, the female nurses rendered great and immediate assistance, but he evidently views them with distrust. He reproaches them with hampering rapid movements and with a distaste for the discomforts inseparable from hastily constructed hospitals and quarters. He holds very strongly that under no circumstances ought the female nurse to be entrusted with duties in division hospitals which require to be shifted with great promptness as and when circumstances may require. He is equally convinced that women should not be employed on transports or hospital boats or trains, and he maintains that the nursing under such circumstances would be better done by men. He is good enough to admit that women may find a useful field of activity in the permanent hospitals, where the "discipline of a marching column is not at stake." The tenor of the article is in favour of the organisation in time of peace of a body of men trained to discharge minor medical functions, apparently something on the lines of our Medical Service Corps. Whatever may be

done in this direction, it may be taken for granted that the services of women nurses will always be a necessity under the stress of war. That the change of environment may entail the abandonment of many existing notions of what constitutes feminine delicacy is possible, but so does hospital life under any circumstances. So long as nurses can be made to work in groups and are not left isolated we see nothing in their position that differs in any essential respect from the conditions of their ordinary work. Obviously they must not be near enough to the front to run unnecessary danger of injury from wayward shells, and they ought never to be allowed to form part of a column which is liable to sudden and unforeseen strategical movements. Moreover, the standard of indispensable comfort for women is, and must be, somewhat higher than for men similarly engaged, specially in the matter of sleeping and hygienic accommodation. The advantage of the woman nurse, on the other hand, is that she is always available, without the expense and inconvenience of maintaining large bodies of men systematically trained for this purpose, and the supply is practically limitless. We doubt if any other country in the world is as richly supplied with trained nurses as our own, and indeed we have been the pioneers in and the developers of this great movement. Even at the present time in no other country are nurses so well organised and trained as here and to attempt to exclude them from active service on mistaken notions of propriety would be to incur not only the risk, but the certainty, of a breakdown in our army hospital service.

THE EFFECTS OF ANÆSTHETICS UPON THE KIDNEYS.

SOME recent investigations by Kemp, of New York, show that the physiological effects of the different anæsthetics upon the kidneys have an important bearing upon the employment of the drugs in certain cases. In the first place, with respect to ether, the results point to the fact that this agent "produces a special contraction of the renal arterioles, with a consequent damaging effect upon the renal secretory cells similar to those which follow clamping the renal artery. The kidneys shrink in bulk, and this is succeeded by diminution of secretion, marked albuminuria, and finally suppression." The author concludes, therefore, that ether as an anæsthetic is contra-indicated when renal disease is present, and when, with the albuminuria, there is associated a tendency to pulmonary oedema. It is, however, scarcely needful to observe that renal insufficiency, especially albuminuria, is a most unfavourable complication with which a surgeon can meet in a patient upon whom he contemplates attempting an operation. Moreover, in bad cases of the kind he might even regard the renal disease present as sufficient to contra-indicate any interference upon his part, and under these circumstances there would not be any danger of the symptoms being aggravated by ether, and no necessity would arise for

the use of a general anæsthetic. On the other hand the author points out that his investigations show that the effect of chloroform upon the kidneys is nil. There is no interruption to the secretion of urine during the administration of the drug, and its physiological effects seem to be limited to acting as a cardiac depressant. Again with regard to the A. C. E. mixture, the author states that "if this preparation is administered more as ether is when used alone, then a study of the carotid and kidney tracings shows clearly that we have both the cardiac depression of chloroform and the renal derangement of ether combined." Hence an unfavourable opinion is expressed of this combination of anæsthetic agents, and the author further states his belief that all anæsthetic mixtures are dangerous and of no advantage. Nitrous oxide and oxygen are held to be the least dangerous and the least deleterious to the kidneys. The author draws attention to the fact that in a series of cases he found a marked increase of indican in the urine after ether administration; and that this increase was also noticeable, but to much less extent, after the administration of chloroform and nitrous oxide. In order to determine the precise physiological effect of an anæsthetic the urine should be carefully examined and measured, according to the author, for twenty-four to forty-eight hours before the operation. Then the patient should be catheterised immediately preceding the administration of the anæsthetic, and catheterisation should be carried out directly the administration is stopped, and the urine in each case examined. By this means full details may be obtained of the actual changes which occur. The paper from which these results are quoted is both interesting and instructive, the inquiry being one which deals with a most important subject. However the practical application of the teaching to which the investigations lead, clearly points to the necessity of avoiding the use of ether as an anæsthetic in all cases in which renal insufficiency is suspected. We believe that this precaution has not claimed the attention of anæsthetists generally.

Notes on Current Topics.

What is an Accident?

THE prevalence of the popular practice of insuring against accidents gives a special and practical interest to legal definitions of what constitutes an accident, and the difficulty experienced in arriving at a working definition shows that the question is not as simple as might be thought. A man in New York recently sustained a perforation of the intestines in consequence of having swallowed sharp fragments in his food, and his representatives sought to recover under his accidental policy. The company refused to pay on the ground that, the cause of death was not an accidental injury within the meaning of the policy. Looked at merely as a question to be decided on common-sense grounds, the company is unquestionably in the wrong. If the man had injured

his hand with some of the self-same fragments and had died of blood poisoning, we presume it would have been regarded as an accident, and unless the policy, which is the basis of the contract, distinctly excludes internal injuries, these would necessarily come within its scope. Judicial decisions on this point vary. In New York, for instance, it has been held that swallowing poison by mistake is an accident within the meaning of the policy; but in Illinois, on the contrary, the courts have ruled exactly the opposite. The same points have been raised from time to time in our own courts, and in the case of accidental poisoning we believe we are right in stating that the verdict has been unfavourable to such claims. If the companies wish to restrict the benefits of their policies to external injuries, they must formally state their intention; but in the absence of any specific exclusion, the widest interpretation ought to be placed on the terms of the policy.

The Confectionery of the Future.

THE official organ of the International Commission for the Suppression of Adulteration, the *British Food Journal*, for this month calls attention to an important, but somewhat delicate question in respect of the employment of saccharin in lieu of sugar in the manufacture of jams, confectionery, fruit syrups and the like. Sugar, it is pointed out, is a food, which saccharin is not; indeed, the latter is of the nature of a drug to be employed accordingly. It possesses antiseptic properties which, however valuable to the manufacturer of food stuffs, may, in the long run, prove injurious when taken by persons with normal digestions. Moreover, it enables ingenious traders to give glucose the sweetening power of cane sugar, thus defrauding the purchaser who expects to get, not merely a delicacy, but a food. As the law at present stands, we doubt the possibility of preventing this, the latest form of trade adulteration. The manufacturer does not define the nature of jam, he does not pretend that it contains this, that or the other substance except perhaps the particular fruit by which it is described, so that it would be difficult to bring home a charge of fraudulent substitution. Still, if our jam is not real, where are we? It may come to pass, with the progress of culinary chemistry, that not even the fruit will be thought necessary. There are plenty of synthetical compounds which may be trusted to give the pleasing delusion of a given flavour, but we pity the youngsters who are condemned to lard their slices of bread with a compound of saccharised glucose, coloured with aniline and flavoured with jargonelle pear, for instance.

What is Medical Practice Coming to?

A CORRESPONDENT, writing from a northern town paints a dark picture of medical practice as a means of gaining a livelihood. He says, "It is really too hard. A friend of mine, a practitioner of nearly forty years' standing, told me to-day that he had not received a single new message in a week. The young men seem to get all the work. Each is a specialist, if

you please, or calls himself by some name or other, so that, of course, he is the man for the time being, the youngest being, of course, the most infallible; so on it goes, he in his turn yielding to the next. I do not deny that the quality of the men who enter practice is improving, but concomitantly with the over-packing of the profession there is the greater power of the public to doctor themselves and the combination of these two causes proves disastrous to the Faculty. I observe that no local diseases now are the local expressions of general states, indeed there would seem to be no such thing. Yet I do not know any cause of failure in practice and in giving relief more disastrous than the dreadful habit of treating the disease rather than the patient." This is rather doleful news especially for those practitioners who have attained an age at which their experience might be expected to secure the confidence of the public. The immense improvement that has taken place in the intellectual equipment of the modern practitioner undoubtedly tells heavily against those who were educated on the old lines, hence the preference displayed by a large section of the public for comparatively young men. We have only to compare the frame of mind of "a practitioner of forty years' standing" with that of the bustling young graduate, fresh from the hospital and the laboratory, to understand that the self-confidence and brand-new ideas of the latter must necessarily impress those with whom he makes it his duty to come into contact. Experience is of value only so far as it co-ordinates and develops previous knowledge. It is not of itself knowledge, or, as it has been often observed, the oldest among us would be the wisest *quod absurdum est*.

Accuracy in Dispensing.

JUDGING from the evidence given before the magistrate in some prosecutions recently undertaken by the Fulham Vestry against chemists for selling goods not of the nature, quality, and substance demanded, the pharmacists had better set about remedying their own shortcomings in the matter of accuracy of dispensing instead of worrying about a hypothetical proclivity to error on the part of the much-abused unqualified dispenser. The mixtures on the analysis of which the prosecutions were undertaken proved to contain an excess of the active ingredient—iodide of potassium—to the tune of from 7 to 15 per cent. According to Mr. Umney, who was called as a witness for the defence, a prescription must be considered to be accurately dispensed if the excess or deficiency, as the case may be, does not exceed 9 per cent. As the *British Food Journal* points out, if the same latitude were permitted to a grocer a pound of tea might contain any quantity between 14½ and 17½ ounces. This point, however, did not bear on the result, for the magistrate, perhaps rightly, held that Section 7 of the "Sale of Food and Drugs Act," is directed against adulteration and not against inaccuracy, so that, provided the drugs specified in the prescription are

contained in the medicine, the quantity does not matter. If this be the law then everyone will agree that the law requires amendment, but until we have the pronouncement of a higher court on the matter, we prefer to hold that the magistrate has misapprehended the bearing of the Act. Perhaps it would be too much to ask the Fulham Vestry to incur the expense of an appeal, indeed, as the question at issue affects the honour and integrity of the pharmacists as a body, it would seem that the Pharmaceutical Society is the proper body to take the matter in hand, but this we may be sure they will not do.

The Prince of Wales's Hospital Fund Distribution.

THE report of the Executive Council of the Prince of Wales's Hospital Fund for the past year is more favourable than that of the preceding twelve months. A sum of £42,000—or £19,000 more than on the previous occasion—has been distributed among eighty-two institutions. In pursuing the list of the latter and the awards, several matters worthy of note become apparent. In the first place we are glad to see that the Committee used commendable discretion in refusing aid to those hospitals which did not appear to be in need of funds. By adopting this policy more funds were thus made available for the needy institutions to whom financial assistance was of the utmost importance. Again we note that the Jubilee Hospital has failed to gain any sympathy from the executive committee; the report concerning it is as follows: This institution does not appear to be a hospital in any sense of the word, and its buildings are quite unsuitable for hospital purposes." This is probably the most scathing criticism which this unfortunate institution has so far received. In two cases—the London Ophthalmic Hospital and St. Thomas's—the awards are qualified with the recommendation to appoint an inquiry officer in order to prevent the "possible" abuse by out-patients. We have for some time been under the impression that the inquiry system had not proved to be satisfactory in the London hospitals. At one large hospital the authorities found it to be useless. Upon the whole, however, the report of the council just issued is, we think, likely to give general satisfaction, and to inspire more confidence in the method under which the fund is being administered. It is evident, however, that the fund, by means of making its grant contingent upon certain recommendations of the committee being carried into effect, will eventually come to exercise a good deal of control over the institutions concerned. In other words the likelihood seems to be that in the future the fund will be able to ensure the position of a "Central Hospital board." But whether this will prove to be good or bad for the London hospitals remains to be seen. Meanwhile there is no doubt that any attempt to aggressively make use of power conferred by the fund in regard to recommendations would be resisted by the hospital authorities. So far, however, it may be said that no such aggressiveness has been exhibited.

The Salvation Shelter Decision.

ON appeal to the Queen's Bench decision the London County Council sustained its right to control the semi-charitable night shelters of the Salvation Army. In the lower courts the decision given by the magistrate was that these places did not fall within the provisions of the Common Lodging Houses Act. The contention of the local authorities, on the other hand, was that they were in reality common lodging houses, and should be registered as such. The importance of sanitary supervision of such shelters is obvious, especially in view of the nature of the vagrant population attracted by their accommodation. The stringent rules laid down for common lodging-houses are far more necessary for the shelters, but as a matter of fact they have been hitherto practically able to defy the authorities, and to carry out cleansing, disinfection and other hygienic measures at their own sweet will. This decision of the Lord Chief Justice is, therefore, of first importance, dealing as it does with a class of population difficult to control under any circumstances from a health point of view. We purpose entering into the matter more at length in an early issue, and meanwhile would express our approval of Lord Russell's wish that as far as possible the work of the Salvation Army should not be hampered. Philanthropy, however well intentioned, must not be permitted to block the pathway of preventive medicine.

What is Inebriety?

So far as the indecisive opinion of magistrates can go it was ruled recently in the Brentford Sessions that the habitual taking of drugs is not inebriety within the meaning of the Act. An inmate of a retreat for inebriates near Twickenham had left the establishment and bought cocaine for injection. If he had gone out to get drunk on whiskey this would have been an offence against the law for which the magistrates might have committed him, but it was represented to them by the defending counsel that neither cocaine nor any other hypnotic is mentioned or indicated in the Act, and the magistrates accordingly adjourned the case to enable the prosecution to take further advice.

Sacculated Diverticula of the Gullet.

THE curious and interesting abnormality of oesophageal diverticula is rarely met with. It is most commonly met with in the cervical region, where it often gives rise to a visible swelling after a meal, and at least one case has been recorded in which the patient was able to empty the pouch of food at will. One of the most prominent clinical symptoms is dysphagia, which not infrequently develops to a serious extent within a few months of the recognition of the trouble! In some cases the obstruction to the oesophagus has been so rapid and the difficulty of swallowing so great that a malignant growth has been diagnosed. In such a case emaciation is apt to prove a fallacious sign, as it depends on the difficulty of swallowing a sufficient amount of nourish-

ment, and not on the cancerous cachexia. Curiously enough the irritation of the food retained in the adventitious pouch sets up a pain that is not infrequently referred to the stomach. No satisfactory explanation has hitherto been forthcoming as to the origin of these abnormalities, although it seems reasonable to suppose they are connected with developmental reversions when congenital, but the cause of the acquired condition is unknown. For some unexplained reason these pouches occur more commonly in man than in the opposite sex. Although their occurrence is rare the medical practitioner will do well to have a careful note in his memory as to their chief characteristics.

Formaldehyde as a Preservative of Milk.

THE discussion which has for some time been taking place on milk preservatives lends additional importance to experiments carried out for the purpose of testing the use of formaldehyde in this regard. The whole of the evidence bearing upon the matter according to an American authority justifies the following conclusions, namely, that formaldehyde, used as a preservative, tends to impair the nutritive value of milk, and disturb the processes of digestion, while, in addition, if taken internally beyond a certain dosage, the drug may produce dangerous if not fatal results. We trust that the committee, now sitting for the purpose of inquiring into the adulteration of food products, will bear these facts in mind, and not overlook the possibility of formaldehyde being employed as a preservative of milk.

Slipshod Dispensing.

AN inquest was held a few days since on two inmates of the Crumpsall Workhouse Hospital who had died from the effects of poisonous doses of strychnine administered in medicine by mistake instead of nitrous ether. As it is not the practice at this institution for the dispensers to initial the labels, there were no means of bringing home the responsibility to the careless member of the dispensing staff, three in number. Perhaps this regrettable accident will lead those responsible for the management of similar institutions to enforce rules which, if they will not avert mishaps would at any rate enable them to pounce on the delinquent. We may call the attention of our friends the pharmacists to the fact that this mishap occurred in the hands of qualified dispensers, lest, for polemical purposes, they should proceed to debit it to the persecuted "doctor's assistant."

The Council Vacancy in the Royal College of Surgeons, Ireland.

A MEETING of the Council has been summoned for January 8 to elect a councillor to the vacancy caused by the death of the late Mr. Wheeler. As we have already reported, the vacant seat is contested by Dr. C. B. Ball, regius professor of surgery in the university of Dublin, and surgeon to Sir Patrick Dun's Hospital, and by Mr. Arthur Chance, surgeon to the

Mater Misericordiae Hospital, both of these gentlemen have already served as councillors. The voting is by ballot papers, so that all Fellows of the College, within postal reach, can participate in the election.

The Surgical Treatment of Gastric Ulcer.

THE intervention of the surgeon in cases of gastric ulcer has hitherto been limited to the treatment of those cases where perforation of the organ has resulted from the ulceration. More or less success has attended these attempts to save life under these necessarily fatal conditions. But now it is recommended to deal surgically with another symptom of gastric ulcer—namely, hæmatemesis. Eisendrath has recorded two cases in which he has operated for this condition. In one, that of a woman, æt. thirty-eight, he opened the stomach, after a second profuse hæmorrhage, and found an ulcer on the posterior wall. The ulcer was drawn out, a ligature applied at its base, and it was then excised. The patient made a rapid recovery. The second case was that of a man, æt. 36, for whom gastrotomy was performed for the same reason, and several small ulcers were found. These were treated in the same fashion, and recovery followed. Symptoms of gastric dilatation, however, subsequently developed, for which gastro-enterostomy was performed, a Murphy's button being used. But death took place from peritonitis. Eisendrath thinks that repeated hæmorrhages, or severe ones occurring more than once, are the indications for operating.

The "Internat" Scandal at Paris.

THE *internes*, or resident medical officers of the Paris hospitals, are selected by periodical competitive examination, and as the tenure of office is at least three years, it can well be imagined that great importance is attached to the results of the very severe test to which candidates are subjected. At the last examination in Paris, some misguided individual, or individuals, obtained admission to the Dean's room by burning out the lock with a thermo-cautery, and they then poured sulphuric acid into the box containing the written papers, destroying them for the most part. This scandalous proceeding naturally gave rise to great commotion, and the authorities have had some difficulty in making up their minds as to the best course to pursue under the circumstances, and so far the police have not been successful in tracing the delinquents. Along with this scandal rumours have found currency in the Press bearing on the prevalence of various illegal methods of affording assistance to candidates desirous of reinforcing memory. It has been decided to hold the examination *de novo*, and in future the public will be excluded from the examination hall, at any rate during the written part of the competition. It is surprising, indeed, to find that hitherto the public that is to say, the friends of the candidates, have been allowed free access to the room. It was almost inevitable under the circumstances that abuses should creep in, and it was high time to take steps to ensure the fidelity of the test.

The Employment of Emmenagogues.

THE fallacious importance attached in certain sections of society to the action of emmenagogues justifies an attitude of suspicion on the part of medical men in regard to the use of this class of agent. In the vast majority of instances the demand for a drug of this class arrives from temporary suspension of the menses under circumstances which give rise to anxiety not exactly on account of health. A woman whose periods cease for some reason other than pregnancy to make their appearance at the appointed date may quite possibly think it necessary to consult a medical man, but in such case it is merely because their cessation is associated in the mind of the public with some grave preturbation of health. Now amenorrhœa, apart from pregnancy, occurs only in association with certain well-recognised conditions, anæmia chlorosis, ovarian disease &c., in none of which would emmenagogues do any good or indeed produce any effect whatever. This leads one to ask under what circumstances the use of these drugs is vindicated, if ever. Obviously not in anæmic conditions, in which treatment must be directed to the original affection; clearly also not in diseases of the reproductive apparatus, since their effect could only be to aggravate the morbid state. It will of course be alleged that they may be employed with advantage in cases of functional paresis, that is to say, cases in which there is no particular reason why menstruation should not take place except a certain indolence on the part of the organs concerned. But are there such cases? If the amenorrhœa be due to constipation with consequent depreciation of health appropriate measures will right matters without recourse to an emmenagogue and the same *mutatis mutandum* holds good with regard to the various other causes classified by writers on gynecology as entailing amenorrhœa. Either this medication is useless or it is unnecessary as well as useless. It may be assumed that the very general use of these remedies is due to the quasi-necessity of prescribing something when appealed to by women suffering from amenorrhœa, and not to any conviction on the part of the prescriber that the medication is likely to be of any particular efficacy for the purpose demanded. It is highly probable, indeed, that in the cases of delayed menstruation bread pills would produce much the same effect, namely, to give an excuse for patience until such time as the function reasserts itself.

The Growth of the Nails.

It has been stated that, as a general rule, the growth of the nails progresses at the rate of about one twenty-fifth of an inch per week, so that nails of the average length, say about half-an-inch, would take about a hundred days to grow, though other authorities put the time at from 121 to 138 days. As a matter of fact, the rate of growth varies, not only according to the age of the subject, but also in different subjects of the same age. Moreover, under the influence of a variety of circumstances, the growth

of the nails may vary even in the same individual. A statistical crank who has taken the trouble to investigate the matter very closely notes that in a man of 21 the nail had grown afresh in 126 days; while in one of 31 it took 159 days. In another individual, only one year older than the latter, the growth, however, took 88 days, in a man of 55 it was 110 days before the nail was reconstituted, and in a man of 67, no less a period than 144 days was required. The observer made this curious observation that the instance of most rapid growth occurred in a tuberculous patient suffering at the time from attacks of hæmoptysis. We are told that sea-air stimulates the growth of the nails, while, on the other hand, grave emotions delay growth, and may even lead to shedding of the nails. A point that may possibly possess a certain diagnostic value is his observation that while in diseases of the central nervous system the growth of the nails is usually interfered with, nothing of the kind is observable in functional paralyses. Lastly, the occurrence of cerebral hæmorrhage is stated to put an end to the growth of the nails, but as to this we have our doubts.

The Operator's Responsibility.

A SUIT will shortly come before the Courts in the United States in which a certain well-known surgeon will have to defend himself against a claim for damages based on the ground that he had caused the death of one of his patients by leaving a gauze plug inside the abdomen in the course of an operation. The surgeon throws the blame on his head nurse, whose special function it was to count the sponges and plugs before and after operation. In this case she assured the surgeon that the number was complete, and the surgeon declines any responsibility for her error. Whether the tribunal will uphold this delegation of responsibility is another matter. Technically, the operator is responsible for every detail of the operation and from a professional point of view *qui s'excuse s'accuse*. Whatever may be the practice in America, we believe that in this country no experienced surgeon would leave a detail of this capital importance to anyone. In spite of every precaution instances are on record in which the tearing of a sponge in two, or an unsuspected addition to their number has led to a mishap.

Normal Arsenic.

AT a recent meeting of the French Academy of Medicine, Dr. Gautier described a method which he had devised for the research of very small quantities of arsenic in certain organs, a method which had enabled him to discover in certain organs of the normal organism a fixed quantity of this element. He finds for instance that arsenic is always present in the thyroid gland of animals, including man, and in smaller, but still estimable quantities, in the thymus, brain and skin, and probably also in the pituitary body. Dr. Gautier explains the curative effect of arsenic in certain maladies on the assumption that

it is a normal and essential constituent of particular organs and tissues. However this may be, if his assertion be confirmed, the fact is one of considerable interest to medico-legists.

Army Medical Dispensers.

THE Department has found it necessary to descend from the qualification heretofore recognised for compounders in the hope of attracting candidates. Young men who have passed the "minor" of the English Pharmaceutical Society are now accepted as sufficiently qualified for the position if they have served as dispensers for three years, and have a certificate of character. They will receive, on appointment, 1s. 6d. a day with rations, kit, and free passage out and home, and two months' pay as a gratuity when the war is over.

HOSPITAL residents, medical and non-medical, are peculiarly exposed to the infection of influenza, as long and arduous experience has abundantly shown. Last week, for instance, two of the house surgeons, and two of the house physicians at St. Mary's Hospital, together with a large number of students, were in the throes of this most undesirable malady.

PERSONAL.

MR. ROBERT CUFF, M.B., M.E.C.S., honorary surgeon to the Scarborough Hospital, has been appointed a magistrate for the borough of Scarborough.

PROFESSORS WILLIAM OSLEE and Howard Kelby, of Baltimore, have been elected honorary members of the Royal Academy of Medicine, Ireland.

DR. JOHN MACEWEN, a son of Professor Macewen of Glasgow University, has volunteered for service as a surgeon at the front, and started on Saturday for South Africa.

DR. A. LOGAN TURNER, of Edinburgh, has been awarded the prize of one hundred guineas by the Council of the Royal College of Surgeons, Edinburgh, for his essay on "Racial Characteristics of the Frontal Sinuses."

THE latest telegrams from the seat of war inform us that Sir William MacCormac, Mr. F. Treves, and the Principal Medical Officer, with several assistant surgeons, were at the base hospital in attendance on the wounded as they were brought in during and after the battle on the Tugela.

THE Gold Medal presented to the Royal College of Surgeons, Edinburgh, by Colonel William Lorimer Bathgate, in memory of his late father, Mr. William McPhune Bathgate, F.R.C.S.E., has been awarded, after the usual written examination in *Materia Medica*, to Mr. David Mitchell, student of medicine, of Broxburn.

THE funeral of Sir Richard Thorne-Thorne, late principal medical officer to the Local Government Board, took place at Woking on Thursday last, and was

attended by Sir Dyce Duckworth, representing the Royal College of Physicians of London, Sir Hugh Owen, Dr Whiteley, from the Home Office, several officials from the Local Government Board, and a large number of medical friends.

DR. W. W. IRELAND, Medical Superintendent of Mavisbank Asylum, Midlothian, has been elected a corresponding member of the Societa Freniatria Italiana, of which Professor Tamburini (of Modena) is president.

A TELEGRAM has just reached Colonel Hughes, C.B., C.M.G., of Guildford, from General Sir Redvers Buller announcing the death of his son, Captain Matthew Hughes, M.D., Royal Army Medical Corps. at the battle of Colenso. General Buller adds, "We had all grown so fond of him."

MR. WILLIAM ANDERSON, F.R.C.S., of St. Thomas's Hospital, and Mr. H. W. Page, F.R.C.S., of St. Mary's Hospital, were re-elected on Thursday last as members of the Court of Examiners of the Royal College of Surgeons, England, and Mr. Bernard Pitts, F.R.C.S. was elected to fill the vacancy occasioned by the retirement of Mr. Edmund Owen, F.R.C.S.

ON the invitation of the War Department, Sir William Stokes will proceed to South Africa as consulting surgeon to the forces as soon as he can make arrangements for the journey. Sir William is the first Irish surgeon whose services have been requisitioned by the Government, and his experience as surgeon, formerly to the Richmond Hospital, and now to the Meath Hospital, fully justifies his selection by the Government to occupy a prominent position in the surgical work of the war.

THE CURE OF CONSUMPTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The only good sense expressed at the meeting, reported in the daily journals on Tuesday, the 19th inst., was when Sir Samuel Wilks seconded the resolution, proposed by the Duke of Northumberland. It seems now that we are not to regard consumption as a disease solely due to the influence of a special bacillus as scarlatina, variola, and other infectious maladies, and upon which theory tuberculin was founded, but as dependent as much or more on the conditions of the atmosphere that surround the individual. Hospitals may be necessary for one class of maladies but for consumption it certainly would be impossible to secure fresh and pure air for the treatment of a disease which runs no definite course and has no resemblance to these fevers. What are we to think then of those who follow the Prince of Wales and at the same time support consumptive hospitals? When the Earl of Derby said that "the remedy for the ignorance which prevailed on this subject was . . . light and air," it appeared as if he thought a great discovery had been made. There is no doubt but that his lordship must have been speaking from personal feeling and experience, and if it has been discovered that ignorance can be cured by light and air it is something to be proud of. We think that some of those who have gone before us held pretty much the same views, centuries back, as we are discovering reasons for doing to-day. Those who know anything of the history of medicine will find that whenever there has been a rush by the public aft

a remedy it has generally, we may say always, turned out to have been a delusion. Society is in a certain hysterical state when it rushes after science in any form. We do not see how this new theory can find any reason for "appealing to the public for the means of establishing new hospitals." It seems difficult to support the hospitals we have, and we fear that Charity is finding other objects, and will do so for some time than hospitals, for the treatment of such diseases as consumption, which are generated in the evil conditions of crowded cities, and which are cured by that life in the country which makes men better fitted to be soldiers and active workers. The kind-hearted men who are supporting the Prince of Wales both in this move for cure of consumption and in other matters of medical interest would do well to be careful lest their work bring no result but disappointment.

I am, Sir, yours truly,

A SYMPATHETIC CRITIC.

THE IRISH COLLEGE OF PHYSICIANS AND THE APOTHECARIES' HALL, IRELAND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I observe in an article in the MEDICAL PRESS AND CIRCULAR of the 21st inst., referring to my statement at the last meeting of the General Medical Council of the reasons why the Royal College of Physicians in Ireland declined to enter into a conjunction with the Apothecaries Hall of Dublin, you say that "the representative of the Irish College of Physicians raised, for the first time, certain technical objections." This is a mistake; these objections have been urged over and over again. Not only at the meetings of the College from time to time to my knowledge for the past forty years, but also at conferences, with deputations from the Council of the College of Surgeons in 1849, and subsequently, and lastly, a tabulated statement of them was printed and laid before the General Medical Council by me at the meeting of the Council, November, 1895.

I am, Sir, yours truly,

Dec. 24th, 1899.

LOMBE ATTHILL.

[It does not seem to be a matter of much importance whether these objections were publicly raised by Dr. Atthill's College, now, or at some previous time; but as he questions our accuracy, we may say that we have searched the volume of minutes and reports of the General Medical Council for 1895, and can nowhere find a statement on behalf of Dr. Atthill's College, of these objections. We know that a printed statement as to the deficiencies of the "Hall" examinations was circulated, but we cannot recollect that any statement of these objections was contained in it. The incident may pass, inasmuch as we have not, for the present, questioned the validity or force of Dr. Atthill's objections.—ED.]

Obituary.

MR. WILLIAM CADGE, F.R.C.S.

THE death is announced, at the ripe old age of 75, of that veteran surgeon, Mr. William Cadge, F.R.C.S., at Lowestoft. His name, it may truly be said, has been a household word in the counties of Norfolk and Suffolk for nearly half a century, and as a correspondent observes, no surgeon has been held in higher estimation than him since the death of "old" Crosse of Norwich. Mr. Cadge was educated at University College Hospital, just at the time when Robert Liston was at the apogee of his reputation as an operating surgeon. Mr. Cadge became a member of the Royal College of Surgeons in 1845, and forthwith became Liston's private assistant, and he remained such until Mr. Liston's death in 1847. He was subsequently appointed demonstrator of anatomy in University College, and assisted Morton in producing his anatomical plates. In 1848 he became a Fellow of

the College of Surgeons, and in 1850 he was appointed Assistant Surgeon of University College Hospital in succession to Mr. Erichsen. This appointment, however, Mr. Cadge did not hold long, for two years later, a vacancy occurring at the Norfolk and Norwich Hospital, he returned to his old home and began practice in Norwich. There he carried on for many years a most successful and lucrative practice, being the recognised consultant for the eastern counties. As an operator, particularly in the operations for stone in the bladder, Mr. Cadge soon achieved a great reputation, and the museum at the Norwich Hospital contains innumerable trophies of his skill in this department. Mr. Cadge married the sister of the late Sir Richard Quain, but had no family, and his wife predeceased him. He took an active interest in municipal matters, and was on one occasion Sheriff of Norwich. He was a liberal supporter of his hospital, having on two occasions presented the charity with the munificent donation of £10,000. When he retired from the active duties of the staff, he was elected consulting surgeon with the right, which he occasionally exercised, to occupy a few beds with his patients. Mr. Cadge was elected a member of the Council of the College of Surgeons of England in 1880 and held office for 16 years, and was Hunterian Professor of Surgery in 1886, when he chose for his subject lithotomy and lithotripsy.

DR. W. N. THURSFIELD, OF SHREWSBURY.

DR. W. NEALOR THURSFIELD, whose death occurred on Wednesday last at his residence, Kingsland, Shrewsbury, was born in the same county in which he lived for 59 years and died. He was educated first at Marlborough College, following his medical studies at King's College, London, and subsequently at Edinburgh University; passing his membership examination of the Royal College of Surgeons, England, in 1861, and next year he took his M.D. degree at Edinburgh. He then commenced practice at Wellington, Salop, where he was appointed medical officer for the town, and soon built up a large private practice. It was, however, as medical officer of various rural districts in the county of Salop that he was best known. Since 1873 and up to a year or two ago he held the position of medical officer of health for the Shropshire combined sanitary district. In addition, he was medical officer for several sanitary districts that either overlapped the county boundary or were entirely outside. It is probable there was not another medical officer in England who covered so much ground as medical officer as Dr. Thurstfield did. About two years ago he was appointed to the newly constituted position of medical officer of health for the county of Salop. Failing health, however, led to his taking steps for relinquishing the position, and it was only at the last meeting of the County Council that his resignation was received. Paralysis was the immediate cause of death.

Literature.

GILLESPIE ON MODERN GASTRIC METHODS (a)

THE hope of the author that this work may serve a useful purpose is certainly fulfilled when the description of the methods employed is based on his personal acquaintance with the processes to which a careful perusal points as those that have particularly engaged Dr. Gillespie's attention. The first few pages are devoted to a well-made *precis* of modern views on healthy gastric conditions which is followed by details of the methods for obtaining and examining the contents of the stomach, evidently derived from practical experience and familiar knowledge of the means employed, especially in regard to the chemical examination of the

fluid removed from the stomach for the purposes of diagnosis.

There is no doubt that careful description of actual practice in the use of instruments, tests and calculations, used to foster greater precision in our estimate of the conditions on which disorders of gastric digestion may depend, must prove interesting to those who are engaged in the study of this particular subject; while for practitioners of medicine who may not have facilities for carrying out the chemical examinations necessary to enhance diagnostic accuracy, the directions given by the author for the performance of lavage and the simpler clinical tests which do not involve the possession of apparatus and laboratory accommodation are clearly and succinctly set forth.

In this connection, however, we do not always find ourselves in agreement with Dr. Lockhart Gillespie's advice and opinions. We have not found that the lubrication of the stomach tube with the small quantity of glycerine required has caused more irritation of the pharynx than when its use has been omitted, especially if the capital plan of sucking a cocaine pledget, as advocated by the author, is carried out before the passage of the tube. It is no small reduction of the discomfort at first experienced by the subject of lavage to be reassured by a suggestion of easy sliding over his rising gorge, which the careful anointing of the tube conveys to his mind.

Since this book teems with useful detail and practical hints, we are surprised to read the author's directions for dealing with the tube after its removal, and should expect remonstrance from the intelligent patient in these days if we used unsterilised water, and failed to sterilise the tube before passing it into the stomach for the purpose of lavage.

The chapters on chemical examination are most carefully written, and contain original recommendations not to be found elsewhere. The author's method of estimating total acidity, acidity after evaporation, and volatile acidity appears to be an excellent substitute for the more complex plan of Hayem and Winter, and the simple way of determining the digestive power of the stomach contents after removal and filtration advocated on page 98, also deserves attention. Within the limits set by the author it would not be reasonable to demand equality of treatment for the various means employed in modern gastric diagnosis; but we hope that the views of Stein on the absorption of salol from the stomach may not be accepted without further confirmation. Dr. Lockhart Gillespie has not apparently employed the X-rays in combination with Einhorn's stomach bucket for the recognition of the position and motility of the organ, nor does he appear to have any acquaintance with the use of massage in combination with Gunzberg's capsule and the salol test, when we believe it is valuable as an aid to diagnosis. The improvement on Turck's irrigator by Herschell, and the use of the phonometer in the diagnosis of gastric size and position, will doubtless be noted in the second edition of this book, which is sure to create a demand for more information from the same source.

DEMOOR, MARSART, AND VANDERVELDE ON EVOLUTION BY ATROPHY. (a)

WE learn from the preface that this treatise was compiled in connection with a scheme for research work in general sociology elaborated in June, 1894, and was presented to the Institute of Sociology in Brussels. The subject is discussed under three main headings: Part I., The Universality of Degenerative Evolution; Part II., The Path of Degenerative Evolution; Part III., The Causes of Degenerative Evolution. The authors argue that degeneration and progress are really only two aspects of evolution, that is to say, that all progress must, necessarily, be attended by degeneration. The first part of the work is chiefly taken up with the marshalling of examples in the animal and vegetable

(a) "A Manual of Modern Gastric Methods, Chemical, Physical and Therapeutical." By A. Lockhart Gillespie, M.D., F.R.C.P.E., F.R.S.E. 175 pages, 15 illustrations. Edinburgh: Oliver and Boyd, 1899.

(a) "Evolution by Atrophy in Biology and Sociology." By Jean Demoor, Jean Marsart, Emile Vandervelde. Translated by Mrs. Chalmers. The International Scientific Series, Vol. LXXXVII. Mitchell. London: Kegan Paul, Trench, Trübner & Co., Ltd., 1899.

kingdoms of departures from the known forms. In the second part, the question is fully discussed as to whether retrogression is a tracing backwards of progression, and the application of this law to sociological phenomena is reviewed. In the third part, which from a medical aspect is the more interesting, many points are discussed and instances given in relation to the production of degeneration by the atrophy of organs and parts, and a somewhat remarkable chapter is added on the "atrophy" of institutions from lack of use. Any one interested in the subject of sociology and its discussion from a scientific aspect will find in this book much that is instructive and original.

MURRAY'S ROUGH NOTES ON REMEDIES. (a)

We are not surprised to find this useful and suggestive little book now in its third edition. In the present day, when the practitioner is overwhelmed by the host of new remedies that are continually poured in upon him to live their little day and then give way to others, it is quite refreshing to read the experience of a physician who has a good robust faith in the curative powers of calomel, blue pill, arsenic, and last, but by no means least, good liqueur brandy.

Of more modern remedies we find nothing said, except a wise caution against the use of chloral in pneumonia.

Though the use of arsenic in the treatment of chorea and asthma is by no means new, yet it is not everyone who will venture to give to a child such a dose as 15 to 20 drops of Fowler's solution three times a day, for the cure of chorea.

Nevertheless, we have in this book undoubted proof of the singularly curative power of this large dose, while at the same time wise advice is given as to how long it is safe to continue its administration, in view of the occasional grave results of arsenical poisoning of medicinal origin.

The chapters on the use of belladonna in various spasmodic diseases, and of mercury in heart disease are full of sound practical advice, and are thoroughly in accord with our own experience.

The last chapter on the restorative powers of liqueur brandy shows that the author fully appreciates the value of alcohol as a therapeutic agent. His insisting, by no means needlessly, but strongly, on the purity of this remedy as seen in good liqueur brandy would make many a patient say "Dr. Murray is the man for me."

The book is one that cannot fail to commend itself to the busy practitioner as abounding in useful advice drawn from extensive and well-used experience.

ECCLES ON DIFFICULT DIGESTION (b).

Any contribution upon the physiological and clinical aspects of massage from the pen of Dr. Symons Eccles would claim attention, but in the work before us the author has succeeded in materially enriching the literature of the subject by throwing much light upon points which are little known and little understood. However, he is careful to state in the preface that his volume is merely a collection of notes on some cases of difficult digestion due to displacements of certain abdominal viscera, and is not in any sense intended to assume the character of an exhaustive treatise on the subject of enteroptosis. This explanation seems to be necessary, inasmuch as it is elsewhere remarked that only matters are dealt with which have come under the author's personal notice. Thus the work, in providing a clear and detailed account of Dr. Eccles's own methods of treatment and clinical experience, gains both in conciseness and value—as a matter of fact no treatise has been published upon the subject of enteroptosis since Glenard's work appeared in 1885, and for this reason, if for no other, the present volume is likely to supply a want. A detail of some importance is the method of examination resorted to in patients suffering from visceroptosis, and

in this regard the author describes a special apparatus designed by him for the purpose. It consists of a movable frame, swung on two uprights; this is so constructed as to be adjustable to any position, and when a patient is reclining on it the effect is to cause relaxation of the abdominal muscles, by which the abdominal examination is greatly facilitated. The book is rich in detail regarding the clinical examination of the abdomen, and reflects the author's ample experience in this special branch of his subject. There are chapters on gastroptosis, movable kidney, general enteroptosis, and prolapse of the sigmoid flexure, and, with respect to the latter, the author relates three cases in which carcinoma of the rectum succeeded this condition. He attributes the development of the malignant disease to the irritation of the bowel set up by the prolapse—a clinical observation, the possibility of the correctness of which should be borne in mind. In conclusion, we can only say that the perusal of Dr. Eccles's work has convinced us that as a personal record of clinical experience and facts in connection with the comparatively little known subject of enteroptosis the volume before us is both valuable and instructive. A word of praise is due to the publishers for the excellent 'get-up' of the work.

CAMPBELL ON THE NERVOUS SYSTEM (a).

The aim of the author is brevity and simplicity, and in this he has been successful. He has not been tempted, like so many writers on neurological medicine, to give a copious anatomy and physiology, too often a mere paraphrase or reprint of what has appeared before, rather does he confine himself to elementary outlines, clear, precise, and freshly interesting. The chapter on the general structure of the central nervous system, for example, is well conceived, and the idea of the neuron is clearly conceived, without superabundant references, and the illustrations though few, are quite sufficient, and serve their purpose fully. The illustrations of brain cells in Fig. 2 are interesting and helpful, in view of modern histological teaching. The second and third chapters deal with the sensory and motor systems respectively, and are equally characterised by clearness and directness. They are sufficiently informative for the average medical man; indeed, this may be said of the book generally. The method and arrangement throughout are very good, and by means of practical tables of comparison, graphic diagrams, and many excellent photographs the reader is provided with as quick a means of getting at some of the leading facts of the nervous system and its diseases as we can remember ever having seen. Much, of course, is left out, even in the way of leading facts, and we should have preferred to see a few chapters devoted to systematic descriptions of nervous diseases; but so far as it goes the book is well done, and worthy the attention of those who are on the threshold of neurological study.

CABOT'S SERUM DIAGNOSIS. (b)

We have read with interest Dr. Richard C. Cabot's "Serum Diagnosis of Disease," and can strongly recommend it to those who wish to become acquainted with this method of investigation. In the case of typhoid fever the extreme value of aids to diagnosis is universally admitted, and a very practical application of its utility was afforded during the Spanish-American war. Fevers were rife among the troops in Cuba and Porto Rico, but until the serum diagnosis threw light on the cases it was impossible to distinguish with certainty between typhoid, malaria, yellow fever, and dysentery. Dr. Cabot himself went to Porto Rico in the hospital ship, *Bay State*, and at Ponce he found hundreds of cases treated for malaria, which Vidal's reaction proved to be typhoid. The author shows that the principle is capable of almost

unlimited extension, and that it is applicable to the diagnosis of a variety of diseases, including glanders, Malta fever, yellow fever, cholera, bubonic plague, anthrax, pneumococcus, streptococcus, bacillus coli and other infections, tuberculosis, diphtheria, relapsing fever, &c. Perhaps he rides his hobby too far, though we admit that he makes out a case for the use of the method in the diagnosis of Malta fever, cholera, and relapsing fever. In the case of non-motile organisms the specific reaction is indicated by a peculiarity of growth of the organism. As might be anticipated, most attention is given to the Widal reaction in typhoid fever, and very full and clear instructions are given for performing the test. Regarding the time limit and dilution the author sums up, "One to forty is a proper dilution with a time-limit of one hour, one to ten is equally reliable with a fifteen-minute limit. Out of 5,978 cases of typhoid, a positive reaction was found in 97.2 per cent.; and out of 849 cases tested before the eighth day, the reaction was present in 93 per cent."

The compilation of the work entailed a vast amount of research into recent medical literature, and the only fault we have to find with the very complete bibliography, is that no attempt is made to separate the wheat from the chaff.

YEAR-BOOK OF PHARMACY (a).

It has been for a long time recognised that the medical art in its broadest sense has become too extended to be embraced in all its stages by any one life or intellect, that it is necessarily breaking up into specialities; and that not the least of these is the complete and scientific study of practical pharmacy, by which alone can we hope to ultimately secure a national or better still an European international pharmacopœia of completeness, accuracy (and, let it be added), with a general rejection of old and exploded remedies, and worthy to take rank with the general advance of medical science. There are few more useful contributions towards this end than the Year book of the Pharmaceutical Conference, which after so many years has become quite an institution, and which now appears with its usual commendable promptitude. The central pivot is of course the July meeting at Plymouth, which was opened by the inaugural address of the President, Mr. J. C. C. Payne, of Belfast, in which he gave an interesting account of the progress of pharmacy and of the history of the foundation of the Pharmaceutical Society of Ireland, and also of the legislation for the regulation of the sale of poisons. In the course of his address he mentioned an interesting fact which is not known as generally as it might be, viz., that so far back as 1760 the Royal College of Physicians of Ireland endeavoured to make a regulation that all poisonous remedies should be dispensed in three-cornered bottles, and innocuous ones in round phials; that effort this college was still making during the present year, and it is likely now to be accomplished; but we do not like to think how many useful lives would have been saved had legal difficulties not intervened during the past nearly a century and a half to retard this vital reform. The President gave also an interesting history of the various local pharmacopœias, which are now remembered by the older school only; and which culminated in the adoption of the first British Pharmacopœia; remarking that the Dublin Pharmacopœia of 1850 was the first to use the English language, and to employ avoirdupois weights instead of the old Troy ones.

The papers on practical pharmacy were very valuable indeed, and the discussions, in which Professor Attfield and other eminent experts took part, were as interesting as the papers themselves. There was a series of papers on the Ipecacuanha compounds of the last edition of the B.P., in which the question of ascertaining the standardised strength of preparations was very judiciously handled. There was a very good communication on the

best plans of determining the percentage of pure iron in ferrum redactum, and another on Jaborandi and Pilocarpin, and on the determination of low percentages of diabetic glucose. The paper on "suggested standards of purity for foods and drugs" was listened to with much interest: the writers justly remarked that in addition to the classes of pure and of adulterated food there might be a third class of "specimens of inferior quality, but not necessary adulterated." "They also properly remark that we have no legalised standards at all, except in the case of spirits, and in the case of a few articles of food, the limits adopted by the Inland Revenue authorities are known (as in the case of milk) and are probably used by most Analysts." To this they might have added tobacco, our fiscal authorities showing the most conscientious care in insuring the purity of this article. No one will doubt the absolute necessity for such legalised standards of every species of food, where such is possible; it would protect the public and the trader as well; and would put an end to those unseemly squabbles between the experts of prosecution and of defence, who too often contradict each other flatly in our Courts, to the scandal of science; and the worst of it is that these experts on both sides are generally both honest and competent, but contradict each other on oath because their standards of purity are different; on the percentage strength of a sample of whiskey they would be sure to agree. It seems to us that the test standards of the B.P. are sufficient for public protection, as regards drugs; the writers seemed to desire something more. Most unfortunately this paper was not discussed on the ground of "want of time," but more probable was the reason put forward by another speaker that "on some of these points they would be touching on rather tender ground, and that the subject would be much better discussed in the Press than in that room, where the temperature, already fairly high, would probably rise rapidly." This matter, however, must be faced, and the problem legislatively solved.

The year book of pharmacy (the first part of the volume) is divided into three sections, viz.: 1. "Chemistry"; 2. "Materia Medica and Pharmacy"; and 3. "Notes and Formulae." These consist of short abstracts and extracts, taken from the Journals of the whole world, of matters of interest and of novelty on these important subjects; this department is most carefully and efficiently carried out by the accomplished editor, Mr. Louis Siebold; it contains such a mass of useful details for everyday work that it would be impossible to summarise it; our only advice to our readers is, get the book and read it. A very complete index enables the reader to lay his hand at once on any point, or to investigate any department.

MEDICAL ANNUAL SYNOPTICAL INDEX. (a)

For the past twelve years Wright's "Medical Annual" has furnished its readers with a well digested summary of the progress of medical science. Each volume was furnished with a good index, and the matter was, as a rule, arranged alphabetically; thus reference was facilitated to the utmost.

But the busy practitioner found as years went by and the goodly row of the "Annual" filled his shelf that searching indexes was too great a tax on his time and patience—the something he sought escaped him; and he regretted that he had not a handy volume giving an index for the whole twelve volumes.

The want has been met—met in the best and most praiseworthy fashion by the synoptical index. A perfect gem of an index, with cross references, a supplemental index, and a synopsis of each article arranged chronologically.

Every fact likely to be wanted in every-day practice on disease, its therapeutics, and on new remedies is included, and so helpful is the volume that we think practitioners who do not possess the Annual for years past

(a) "The Year-Book of Pharmacy, comprising abstracts of papers relating to Pharmacy, Materia Medica and Chemistry, from June, 1898, to July, 1899. Further, the transactions of the thirty-sixth annual meeting of the British Pharmaceutical Conference, held at Plymouth during July, 1899." London: J. and A. Churchill. 8vo, pp. 517.

(a) "The Medical Annual Synoptical Index to Remedies and Diseases. For the Twelve Years, 1887 to 1899." Bristol: John Wright and Co. 1899.

cannot make a better investment than in securing a copy of the Index, and those just entering on practice will at a glance find in its pages the most approved methods of treatment.

The arrangement of the book into sections on (1) remedies; (2) diseases; (3) alterations in the 1898 B.P.; (4) test types; (5) memoranda; and (6) a supplementary index, is excellently carried out.

The multitude of facts compressed into the small compass of its four hundred pages make the book one of permanent value, both to students and practitioners of medicine.

Medical News.

The Queen's Colleges in Ireland.

THE recent very undignified and unpleasant disturbances at the visitation of the Queen's College, Cork, arose chiefly from the judgment of the visitors that it is impossible, under existing circumstances, to establish a professorate of Pathology in the College School. The Belfast College students have followed the lead of their Cork brethren, and it is not surprising that they should do so considering that pathology is, according to present day opinion, one of the most important subjects of the student's education. The only obstacle in the way of the establishment of such a chair is the parsimony of the Treasury which, in this case is ridiculous, hair splitting. We offer to the students of the Queen's Colleges our sympathy with their very reasonable demand.

We have not the same sympathy with the complaint of the Belfast school that their teachers are not appointed, in due proportion, as examiners in the Royal University. According to our old-fashioned ideas the examinations of a great university ought to be conducted by examiners totally independent of school interests, though we well know that an examinership is a valuable asset for a medical school, and we hold very strongly that an educational institution humiliates itself when it allows itself to be made the creature of any medical school on religion or politics.

The "Purser" Testimonial.

THE movement set on foot by the pupils of Professor Purser, the Professor of Physiology in the University of Dublin, to present to him a testimonial on the occasion of the completion of his twenty-fifth year of Professorship, has resulted in the foundation of a Medal in the Trinity College School. The subscribers to the fund have arranged that the occasion shall be celebrated by a dinner to the Professor, which will be held at the Shelbourne Hotel, Dublin, on the 25th inst. Dr. Kirkpatrick of 23, Lower Baggot Street, Dublin, is the treasurer in charge.

The Vacant Surgeoncy of the City of Dublin Hospital.

It is announced in our advertising columns to-day that applications for the Surgeoncy vacated by the death of Mr. Wheeler, will be received up to the 5th of January, but no day for the election has yet been fixed, nor can it be so until the Medical Board has decided upon the applicants whom they will recommend to the Governors. The list of candidates which is published by a contemporary is therefore entirely speculative and unauthorised, nor does it contain the names of all the gentlemen who are currently named as likely to compete.

Vital Statistics.

THE deaths registered last week in thirty-six great towns of England and Wales corresponded to an annual rate of 22.0 per 1,000 of their aggregate population, which is estimated at 12,786,832 persons in the middle of this year:—

Birkenhead 14, Birmingham 22, Blackburn 17, Bolton 16, Bradford 20, Brighton 20, Bristol 21, Burnley 16, Cardiff 19, Croydon 20, Derby 14, Dublin 38, Edinburgh 17, Glasgow 22, Gateshead 16, Halifax 17, Huddersfield 9, Hull 22, Leeds 20, Leicester 22, Liverpool 26, London 23, Manchester 18, Newcastle-on-Tyne 19, Norwich 16, Nottingham 19, Oldham 19, Plymouth 27, Portsmouth 30, Preston 25, Salford 23, Sheffield 21, Sunderland 20, Swansea 24, West Ham 15, Wolverhampton 24. The highest death-rate per 1,000 living, as measured by last

week's mortality, were:—From measles 1.2 in Liverpool, 1.4 in Sheffield, 1.8 in Birkenhead, 2.0 in Swansea, and 3.1 in Preston; from scarlet fever 1.1 in Bradford; from whooping cough 1.0 in Leicester, 1.2 in Blackburn, and 1.4 in Norwich and in Salford. In none of the large towns did the death-rate from fever or from diarrhoea reach 1.0 per 1,000. The 128 deaths from diphtheria included 55 in London, 16 in Leeds, 11 in Sheffield, 8 in Portsmouth, 5 in Leicester, 5 in Liverpool, 4 in Norwich, 3 in Brighton, and 3 in Birmingham. Twelve deaths from small-pox were registered in Hull and 1 in London, but not one in any of the other large towns.

PASS LISTS.

Royal College of Surgeons in Ireland.

THE following candidates having passed the necessary examination have been admitted Fellows of the College:—Mr. J. T. Abbott, Mr. R. J. Coulter, Mr. T. Gilchrist, Mr. R. D. Joyce, Mr. D. A. McCurdy, and Mr. H. W. Dulton.

University of London.

THE following is the official list of successful candidates who passed the necessary examinations during the present month:—

M.D. EXAMINATION. MEDICINE.

Alford, Cyril Wolrige	Hodgson, Curtis Rawthorne
Armitage, Frances, B.S.	B.S.
Ashwin, Richard Hamilton	Horder, Thomas Jeeves, B.Sc.
Banting, Cecil, B.S.	Horne, W. Ernest L., B.S.
Benham, Charles Henry	Houtton, Ernest Henry
Bostock, Eustace Bernd., B.S.	Huggins, Sydney Penrose
Box, Stanley Longhurst	Jenkins, John David, B.S.
Bruce, Harold Wilson, B.S.	Leon, John Temple, B.Sc.
Buckley, Charles William	Maxwell, James Laidlaw, B.S.
Burn, Alfred	Mayston, Robert William
Cleveland, Arthur John	Nalacro, David Nunes, B.Sc.
Cornish, Sydney, B.S.	(Gold Medal.)
Coutts, John Morton Sim	Norman, Richard Henry, B.S.
Cunliffe, Thomas Varley, B.S.	Perry Sidney Herbert
Currie, John	Pugh, John Williamson
Fletcher, Frederick John, B.S.	Robertson, Frederick W., B.S.
Goffe, Ernest, Geo. Leopold, B.S.	Slater, Geo. Nathan Osceft
Greenwood, Frank Redmayne	Stirling, Hubert John
Gullan, Archibald Gordon	Stoney, Florence Ada, B.S.
Harris, Charles Poulett	Williams, Percy Glyn S., B.S.
Hibbert, Joseph Coote	

STATE MEDICINE.

Gully, Robert Cullum, M.D.	Weir, Arthur Nesham, B.Sc.
Jackson, Herbert William	

B.S. EXAMINATION.—FIRST DIVISION.

Bucknall, Thos. Rupt. H., M.D.	Trotter, Wilfred B.L., M.D.
Roberts, Adeline Mary	Turnbull, Jane Holland
Stevenson, Mabel Geraldine	Turner, Philip, B.Sc.

SECOND DIVISION.

Anderson William Maurice	Meachen, George Norman
Andrews, Hy. Russell, M.D.	Meakin, Ethilda Budgett M.
Arter, Arthur Hunton	Murrell, Christine Mary
Chadburn, Maud Mary, M.D.	Sayer, Ettie
Dobson, Joseph Faulkner	Sprawson, Cuthbert Allan
Ferris, William	Stewart, Mary Ariel
Hilton, C.leb Thomas	Stewart, Walter Grahame
Howell, John	Strange, Robert Gordon
Iles, Mary Muriel Griffin	Vernon, Ethel Miller
Martindale, Louisa	Watts, Eliza Turner

M.S. EXAMINATION.

Bonney, Wm. Fras. Victor,	Handley, Wm. Sampson, M.D.
M.D.	Milton, William Taylor

Royal College of Surgeons, Edinburgh.

AFTER having passed the requisite examinations the following candidates were, at a meeting held on December 15th admitted Fellows of the College:—

Hugh Bennett, M.B., C.M. Edin., Captain, Indian Medical Service; Charles William Booker, M.B.C.S. Eng., John Clark M.D. Edin., William Henry Cooke, M.B.C.S. Eng., Charles William Dean, L.R.C.S.E., William Evans, M.B.C.S. Eng., Alfred Joseph Martineau, M.B.C.S. Eng., Alexander Glen Park, M.D. Glasg., David Richard Rowlands, M.B., C.M. Glasg., Robert Basil Stamford, M.B.C.S. Eng., and James Whitton, L.R.C.S.E.

Society of Apothecaries, London.

The following candidates passed during December in Surgery: T. B. Haig, Section I.; J. B. Hall, Section II.; T. E. Holman; C. Johnson, Section I.; G. G. Membership, Section II.; O. H. Rogerson, Section II.; M. J. Ryan; O. C. Sibley; H. E. Weston, Section I.

Medicine: G. H. Bedford, Section II.; W. F. C. Bennett, Section II.; E. Grange; K. Grube; H. N. Morton, Section II.; G. G. Membership, Section II.; O. H. Rogerson, Sections I and II.; G. H. Watson.

Forensic Medicine: Dady, F. C. H., Elias, F., Grange, E., Grube, K., Rogerson, O. H., Watson, G. H. Midwifery: Amos, C. B. S., Brooks, C. E., Cox, W. A. C., French, W. D., Furness, J. C., Lucas, G. R., Roberts, W. Rogerson, O. H., Smith, C. V., Worts, C. C.

The Diploma of the Society was granted to the following candidates entitling them to practise Medicine, Surgery, and Midwifery: Messrs. G. H. Bedford, C. E. Brooks, F. Elias, J. B. Hall, G. G. Membership, O. H. Rogerson, O. C. Sibley, and C. C. Worts.

Notices to Correspondents, Short Letters, &c.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them, at half the usual cost, on application to the printers before the type is broken up.

THE SWEETENING POWER OF SUGAR.

ACCORDING to the N.Y. *Medical Record*, the sweetening powers of sugar in powder are decidedly inferior to those of the coarsely crystallised article. In the process of pulverisation it is surmised that the heat or electricity transforms part of the sugar into glucose; the sweetening effects whereof are only about a third of saccharose.

M. E. SEIRS.—We are not aware of any concerted measures having for object the destruction of sewer rats, nor, indeed, unless with some special object in view, such as the prevention of plague, do we think their wholesale destruction is a thing to be aimed at in view of the usefulness of their role as garbage consumers. In certain foreign seaports attempts have been made to asphyxiate these rodents by chemical means, but we are unable to say with what amount of success.

M.B.C.S.—Dr. Mayer's abortive treatment of tonsillitis consists in the hourly administration (to begin with) of teaspoonful doses of the following mixture: sulphate of morphine, gr. 1; tincture of green hellebore 1dr, water 4oz. Dr. Mayer states that retrogression of the symptoms of acute tonsillitis often follows this medication within twenty-four hours. Should this not be the case, it is useless to persevere.

CASE OF EXTENSIVE SUPPURATION OF THE ABDOMINAL WALL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your journal of December 6th (p. 580) I am represented as having reported that in a case of extensive suppuration of the abdominal wall "the body of the uterus had disappeared." This is a mistake. If you will permit me I will send you the notes of the case, a very remarkable one of perforation of the uterine wall, though not quite so remarkable as you have reported it, and you may possibly think them worthy of publication.

I remain, yours obediently,

C. B. KEETLEY.

56, Grosvenor Street, W.

Dec. 20th, 1899.

[We shall be glad to receive Mr. Keetley's notes.—ED.]

EXETER.—You are quite right in giving a guarded prognosis in the case. It not infrequently happens that in the earliest stages of pulmonary tuberculosis, tubercle bacilli may not be detected in the sputa. Indeed they are not discoverable until some breaking down of the lung tissue has taken place. In view of the family history, to advance an adverse opinion was a hazardous step. In any case you have taken the proper scientific attitude and may calmly await the issue of events.

AN EDINBURGH STUDENT.—You are a little out in your data. Galileo made his discovery of the isochronous oscillations of the pendulum when a student at Pisa at the age of eighteen, applying it soon after to determine the beat of the pulse—still an expedient in everyday medical practice; and he constructed a pendulum for the purpose, giving it the name of *pulsiogium*. He invented the thermometer fifteen years later, in 1597, and microscope in 1609.

M. G.—A marked feeling of fatigue and lassitude on rising, in the absence of a specific cause, is, or may be, the first signs of incipient neurasthenia. Before regarding it in this light, however, it is necessary to exclude visceral and other causes, because, though the significance of the symptom is the same, its importance from the point of view of diagnosis and prognosis varies according to the physical basis which has given rise to it.

AMBIGUOUS!

THE New York *Medical Record* mentions that a new book by Dr. Weiss Mitchell is on the point of publication, with the suggestive title "The Autobiography of a Quack."

DR. RAND.—The distressing phenomena occasionally induced by thyroid medication may, it is stated, be averted by administering arsenic at the same time. There is sufficient clinical confirmation

of the statement to warrant a trial, at any rate, and possibly your difficulty in the case referred to may thereby be obviated.

Appointments.

- BENNETT, W. F. C., L.R.C.P., L.R.C.S. Edin., Assistant House Surgeon to the Rotherham Hospital and Dispensary.
COLLIER, JAMES, M.D., M.R.C.P., B.Sc., Registrar to the National Hospital for the Paralyzed and Epileptic, Queen Square, London.
ELLIMAN, A. C. L.R.C.P. Lond., M.R.C.S., Medical Officer by the St. Saviour's Board of Works, London, pro tem.
GREENSILL, J. H., M.R.C.S., Medical Officer of Health for the Martley Rural Sanitary District.
HAYES, G. CONSTABLE, F.R.C.S., Eng., Assistant Ophthalmic and Aural Surgeon to the Leeds General Infirmary.
LUNT, D. C. M., L.R.C.P. Ire., L.R.C.S. Edin., M.B.C.S., Medical Officer of Health for the Lymington Urban Sanitary District.
MACCALLAN, A. F., B.A., M.B., B.C., F.R.C.S., L.R.C.P., Junior House Surgeon to the Royal London Ophthalmic Hospital.
NEWBY, T., M.D. St. And., M.R.C.S., Medical Officer of Health for Great Grimsby Town Council.
PARSONS, W. BROCK, M.R.C.S., L.R.C.P. Lond., Resident Medical Officer to the North-West London Hospital.
PUGH, E. M.B., Ch.B. Edin., Senior Assistant Medical Officer for the Birmingham City Asylum.
ROBERTS, C. HUBERT, M.D. Lond., F.R.C.S., M.R.C.P., Physician to Out-patients, Queen Charlotte's Lying-in Hospital, London.
RUSSELL, C. H., L.R.C.P. Lond., M.R.C.S., D.P.H., Medical Officer to Great Yarmouth.
SMITH, W. E., M.B., C.M., Senior House Surgeon to the Royal London Ophthalmic Hospital.
STANWELL, ST. JOHN, M.B., M.C. Edin., M.R.C.S., Surgeon to the Stamford and Rutland General Infirmary, Stamford.
TYRRELL, F. A. C., B.A., M.B., B.C., M.R.C.S., L.R.C.P., Junior Surgical Officer to Out-patients, Royal London Ophthalmic Hospital.

Vacancies.

- Bristol Royal Hospital for Sick Women and Children.—House Surgeon. Salary £100 per annum, with rooms and attendance (not board).
Bristol City and County.—Medical Officer for the Workhouse. Salary £250 per annum. Apply to the Clerk to the Gurradians, St. Peter's Hospital, Bristol.
City of York.—Medical Officer of Health. Salary £400 per annum. Apply to the Town Clerk, Guildhall, York.
East Sussex County Asylum, Haywards Heath.—Third Assistant Medical Officer. Salary £175 a year, without board or lodging.
Leicester Infirmary.—House Physician for 12 months. Salary £100 per annum with board, apartments and washing.
Lewes Dispensary and Infirmary and Victoria Hospital, Lewes.—Resident Medical Officer. Salary £100 per annum, furnished apartments, board, coal, gas, and attendance.
Middlesex Hospital, W.—Assistant in the Cancer Research Laboratories. Salary £100 per annum, with an honorarium of £50, after his second year of office.
Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £120 per annum. Special arrangement for board, &c.
Seamen's Hospital Society, "Dreadnought," Greenwich.—Senior House Surgeon for the Branch Hospital, Royal Victoria and Albert Docks, E. Salary £75 per annum, with board and residence, and an additional £25 per annum conditionally.
St. John's Hospital for Diseases of the Skin, 49, Leicester Square, London.—Honorary Assistant Medical Officer. Apply to Secretary.
St. Marylebone General Dispensary, London, W.—Resident Medical Officer. Salary 100 guineas per annum, with furnished apartments, attendance, coal, and light.
Teignmouth Hospital, South Devon.—House Surgeon. Salary £50 a year, with board, lodging, and washing. No stimulants supplied, but in lieu thereof £6 per annum allowed.
Three Counties Asylum, near Hitchin.—Second Assistant Medical Officer. Salary £150 per annum, with board, apartments, washing, and attendance. Apply to the Clerk, St. Neots, Hunts.

Births.

- CRAWFURD.—On December 21st, at 71, Harley Street, London, the wife of Raymond H. P. Crawford, M.D., of a son.
BELL.—On December 19th, at Higher Broughton, Manchester, the wife of Wm. Bruce Bell, M.B., C.M. Edin., of a daughter.
FAICHNIE.—On December 22nd, at 14, Strathray-gardens, London, the wife of Norman Faichnie, Capt. B.A.M.C., prematurity of a son, stillborn.
MACKAY.—On December 19th, at The Cloisters, Knaresboro, the wife of Ian D. Mackay, M.B. and C.M. of a daughter.
ROBERTS.—On December 19th, at Kingsdown, Forest Hill, S.E., the wife of Francis Henry Roberts, M.B.C.S., L.R.C.P. Lond., of a son.

Deaths.

- BRODIE.—On December 16th, at 5, Woodside Place, Glasgow, John Ewan Brodie, M.D., Brig.-Surge. (C.V.I.B. and S.M.O. Clyde Defences).
FLINT.—On December 13th, at Orford, Suffolk, Frederick Sayer Flint, L.R.C.S., L.R.C.P., aged 31.
POPE.—On December 23rd, at Woodriding, Pinner, Mary, widow of John B. Pope, M.R.C.S., L.S.A.
WARING.—On December 12th, at 8, Eaton-road, Hove, Dr. Francis John Arthur Waring, Retired Surgeon R.N., deeply mourned.

EXTRACT FROM THE LANCET, March 5th, 1898:—"Messrs. ARNOLD & SONS, of West Smithfield, inform us that they have constructed a cabinet for the storing of surgical appliances at a price that will place it within the reach of every general practitioner. It is made of iron enamelled white with 4-in. polished plate glass top, back, sides, and door, with two plate glass shelves with polished edges, and is manufactured in two sizes—18 x 15 x 8 in., 35s.; and 24 x 18 x 11 in., 55s. The Cabinet should prove useful to many institutions and practitioners."

ARNOLD & SONS,

F. H. WILLIAMS, M.D., BOSTON, MASS.

"It is simply a mine of wealth both for students and practitioners.
It is thoroughly practical and thoroughly reliable. . . is undoubtedly
the best treatise on the subject in the English language."—*British
Medical Journal*.

"A work which marks a distinct epoch, a turning-point in the
history of medicine. It is not a mere compilation . . . but is
essentially a new departure, breaking away from well-worn tracts into
a new and almost unknown region."—*Medical Times and Gazette*.

BY THE SAME AUTHOR.

Disorders of Digestion : Their Consequences and Treatment.

This work contains, in addition to the Lettsomian Lectures, a number
of other Papers by the Author on similar subjects. 8vo, 10s. 6d.

"Distinguished by accurate observation and original thinking, these
papers have been largely instrumental in moulding current medium
opinion in regard to many of the subjects with which they are con-
cerned."—*Edinburgh Medical Journal*.

"We can cordially recommend the volume as one which combines
such practical and technical information and sound common sense."—
London Medical Record.

ANÆSTHETICS, ANCIENT AND MODERN.
their Physiological Action, Therapeutic Use, and Mode of
Administration; together with an Historical Resumé of the
Introduction of Modern Anæsthetics; and also an account of
the more celebrated Anæsthetics in Use from the earliest time to
the discovery of Nitrous Oxide.

By GEORGE FOY, F.R.C.S.

"Mr. Foy's work will ever remain classical in reference to the history
of anæsthetics, practical in its directions as to the choice and manner
of using them, and deserves a high position in the esteem of every
surgeon."—*Virginia Medical Monthly*, Nov., 1889. "A really useful,
interesting and instructive volume." *Virginia Medical Monthly*,
Dec., 1889. "Not only a valuable addition to the literature of
anæsthesia, but it has a flavour of old-world learning and investigation
that makes it most pleasant reading." *Edinburgh Medical Journal*,
April, 1890. "We congratulate the author on the industry, research
and learning which he has brought to bear upon his work, and we
claim for him to have made a valuable and scholarly contribution to
the literature of anæsthetics."—*Dublin Journal of Medical Science*,
October, 1889.

London: Baillière, Tindall, and Cox, King William Street, Strand.

MEDICAL MAGAZINE.

"IN THE FRONT RANK OF REALLY VALUABLE FOODS."

LANCET.

DR TIBBLES' Cocoa**FAVoured BY THE HOMES AND HOSPITALS OF
GREAT BRITAIN.**

"The Lancet," 22nd July, 1899, says:—

"This brandy shows excellent features on analysis while the evidence of taste is distinctly in favour of the description that it is an old matured grape spirit. It possesses that ethereal fragrance due to the peculiar ethers of wine. Our analysis yielded the following results:—Alcohol, by weight 41.00 per cent., by volume 48.43 per cent., equal to proof spirit 84.87 per cent.; acidity expressed as acetic acid, 0.033 per cent.; extractives 0.69 per cent.; mineral matter, *nil*; alcohol in volatile ethers, two grammes per 10 litres. The

flavour is soft and mellow and the aroma is characteristic of a sound and mature wine-derived spirit. In view of these analytical and general evidences this brandy may be described as particularly suitable for medicinal purposes."

MARTELL'S

THREE STAR

"The Medical Press," 9th August, 1899, says:—

"We have carefully examined a sample of this well-known spirit by the usual tests, and the results obtained by analysis fully warrant our recommending it for medical and dietetic purposes. The analysis gave the following figures:—

Alcohol (as proof spirit)	86.5	per cent.
Extractives68	" "
Ash	Nil.	
Acidity036	" "
Ethers (as alcohol)028	" "

BRANDY.

"We analysed this product some ten or more years ago, and finding that it still maintains its exceptionally high character, we are consequently in a position to speak highly of it as a genuine old brandy made from wine, well matured, and free from all compounds which might detract from its value as a medicinal agent."

BENGER'S FOOD.

FOR INFANTS, INVALIDS, AND THE AGED.

This delicious, highly nutritive, and most easily digested food is specially prepared for Infants, and for those Adults whose digestive powers have been weakened by illness or age.

THE FOLLOWING LETTER is PUBLISHED by SPECIAL PERMISSION of THE RUSSIAN COURT:—

"BALMORAL CASTLE, SCOTLAND.

"Sirs,—Please forward to Balmoral Castle one dozen 2/6 Tins of BENER'S FOOD for H.I.M. THE EMPRESS OF RUSSIA, addressed to Miss Coster. We have received the Box ordered from Peterhoff.

"Yours truly, F. COSTER."

Published by Permission of HER ROYAL HIGHNESS PRINCESS ALEXANDRA VON HOHENLOHE:—

"SCHLOSS, LANGENBURG, WURTEMBERG.

"Sirs,—I thought you would like to hear how the little Prince of Hohenlohe is getting on. I have fed him entirely on 'BENER'S FOOD' since he was two and a half months old, and now he is eight months. He is the finest and strongest child I have ever had charge of. He really is a splendid boy, and always so good and happy. He has already four teeth, and has cut them without any trouble.

"I remain, Sirs, yours truly,

MARY GALLOWAY

"(Nurse to the little Prince Gottfried v. Hohenlohe).

"Dec. 5th.

"I shall be very pleased to have my letter printed, or any portion of it you wish. I have the permission of Her Royal Highness Princess Alexandra von Hohenlohe. H.R.H. is very delighted with your food."

The Lancet describes it as "Mr. Benger's admirable preparation."

THE MEDICAL PRESS says:—"Few modern improvements in Pharmacy have done so much as Benger's Preparations to assist the Physician in his treatment of the sick."

The British Medical Journal says:—"Benger's Food has by its excellence established a reputation of its own."

The Illustrated Medical News says:—"Infants do remarkably well on it. There is certainly a great future before it."

A Government Medical Officer writes:—"I began using your Food when my son was only a fortnight old, and now (five months) he is as fine a boy as you could wish to see."

From an Eminent Surgeon:—"After a lengthened experience of Foods, both at home and in India, I consider Benger's Food incomparably superior to any I have ever prescribed."

A Lady writes:—"Really I consider that, humanly speaking, Benger's Food entirely saved baby's life. I had tried four other well-known Foods, but he could digest nothing until we began the 'Benger.' He is now rosy and fattening rapidly."

BENGER'S FOOD is sold in Tins of various sizes by Chemists, &c., everywhere.

Wholesale of all Wholesale Houses and Shippers, or of the Manufacturers,

F. B. BENGER & CO., Ltd., Otter Works, Manchester.

TELEGRAPHIC ADDRESS:—"Benger's, Manchester."

THE "Allenburys" Foods

A Progressive

Series of Foods.

for Infant Feeding.

THE "Allenburys" Milk Foods so closely approximate in composition to the natural food as to supply an artificial diet almost identical with, and in practice found, when intelligently used, to be a reliable substitute for the mother's milk. So much so in this the case that an infant can take these Foods and the breast alternately without any disturbance to its digestive organs.

All ordinary substitutes for the mother's milk fail in some important attribute thus the usual substitute, cow's milk, differs materially in composition, which no amount of mere dilution can correct, being deficient in fat, albumen, and lactose, whilst the casein is in excess. Further, as obtained in towns, cow's milk invariably swarms with bacteria, many of which are pathogenic to the alimentary canal of the infant.

THE

"Allenburys" Milk Food No. 1,

for use from Birth to Three Months,

Affords, when prepared for use, a *correct* substitute for human milk. It is manufactured from fresh cow's milk, so modified as to present all the constituents of human milk, in their true relative proportions. Being in a desiccated form it keeps perfectly and requires the addition of *boiled* water only to furnish a pure and easily digested food suitable for infants during the first three months of life.

THE

"Allenburys" Milk Food No. 2,

for use from Three to Six Months,

This No. 2 Food contains all the elements of human milk in proper proportions. To this is added a small proportion of the soluble products of the action of malt upon wheat, *i.e.* Maltose, Dextrine, and Soluble Phosphates. These ingredients are a valuable adjunct to the increasing needs of the infant economy, yet the Food is readily and easily assimilated, there being no unconverted starch present. This No. 2 Food is designed for children between three and six months of age.

THE

"Allenburys" Malted Food No. 3

for Infants of Six Months and upwards.

This is a farinaceous Food prepared by improved methods after Baron von LIEBIG'S formula. The basis is fine wheaten flour which has been thoroughly cooked and partially digested by an active Malt Extract, so that a large proportion, but not all, of the starch has been converted. It is particularly rich in soluble phosphates and albuminoids. Being a farinaceous Food, it requires the addition of fresh milk in its preparation. This food should be given from six months and upwards.

The "ALLENBURYS" FOODS should be given as directed and not continued beyond the time indicated. Thus the No. 1 Food should only be given during the first three months of life, the No. 2 between the third and the sixth month, and the No. 3 Food after the child is six months of age.

Note.—When infants are reared artificially it is strongly advised that some fresh elements of diet be given. Eminent authorities have recommended that a little raw meat-juice, grape, or sweetened orange juice, be given to or three times a week after the first three or four months. Full directions as to this are issued with each tin of food.

The "Allenburys" Feeder.

This bottle has the nipple at one end and a valve-stopper at the other, so that, both being removed, it can be readily cleansed under the tap. The valve admits air behind the column of milk, thus avoiding the swallowing of air and the resulting wind-colic; while the rubber nipple is easily detached, and can be turned inside out. The bottle is graduated. Price 1/3 each.

BATTLE & CO., St Louis, Mo., U.S.A

Why SCOTT'S is the Best Emulsion.

Because it contains the largest percentage of cod-liver oil.

Because the oil is the best medicinal Norway oil.

Because the oil is in the most perfectly emulsified form.

Because glycerine is combined with the oil.

Because sugar is not used to sweeten it.

Because the hypophosphites of lime and soda add greatly to its medicinal value, and

Because Scott's Emulsion is not only the most palatable of all forms of cod-liver oil, but it can be absolutely relied upon.

Scott's Emulsion retains its form and sweetness indefinitely. It does not grow rancid, and it is tolerated by patients continuously.

The best test of Scott's Emulsion is the practical test. Patients like it, and it does them the most good.

SCOTT & BOWNE, Ltd., Manufacturing Chemists, London, E.C.

'Kepler'

.. Solution

WITHOUT offending the palate or disturbing the digestion, 'Kepler' Solution ensures the absorption of cod liver oil to an extent hitherto impossible. No plain or prepared oil is so acceptable to fastidious invalids and young children or so easily assimilated as this intimate incorporation of the finest Norwegian Cod Liver Oil in 'Kepler' Malt Extract. It is the best preparation of malt and oil which can be produced from the finest materials by the latest and most original methods under the control of experts who have devoted many years to studying the subject. 'Kepler' Solution is supplied in small and large bottles.

Grateful Mothers

and

A Spennymoor, Durham, Lady writes :—

"My baby has been washed with **LIFEBUOY SOAP** since she was two weeks old. She is now six months, and the picture of health."

A Bristol Lady writes :—

"A few weeks ago my little boy had a ringworm on his face. I gave him hot baths at night, using **LIFEBUOY SOAP** freely. When doctor saw the child's face a short time afterwards he was astonished at finding that the ringworm was so quickly removed."

A Pendlebury Lady writes :—

"My little girl recently suffered from eczema. I used **LIFEBUOY SOAP** constantly, and she is now well and healthy and as fair as a lily."

A Leytonstone, Essex, Lady writes :—

"My daughter recently suffered from an attack of eczema in her hands. For two years she attended a hospital, but she was not cured. At last she tried your **LIFEBUOY SOAP**, and is now quite well."

A London Lady writes :—

"My baby was washed with **LIFEBUOY SOAP** when it was born, as my doctor recommended it."

LIFEBUOY Royal Disinfectant SOAP is a powerful disinfectant and exterminator of the various germs and microbes of disease; is made of **absolutely** pure materials; is free from injurious chemicals, and, in use, is at **once** safe, sure, simple, and economical.

BAYER'S PHARMACEUTICAL SPECIALITIES.

PROTARGOL.

A new silver preparation, highly efficacious in the treatment of gonorrhœa (acute: injections of $\frac{1}{4}$ to 2 per cent.; chronic: injections up to 10 per cent.).

Most strongly recommended as a wound healer (either in powder form, or as an ointment of from 5 to 10 per cent.), especially for suppurating wounds, ulcers and burns.

PROTARGOL contains 8.3 per cent. silver, and is easily soluble in cold or warm water, is non-irritating, and possesses a better penetrating effect on the tissues than any other known silver preparation.

PROTARGOL is a chemical compound of silver and a protein substance. Its solution is not precipitated by albumen, chloride of sodium, or diluted hydrochloric acid.

PROTARGOL possesses high bactericidal properties. An eminent English surgeon, in *The Practitioner* for March, 1898, confirms, so far as his experiences go, the favourable opinion expressed by Professor Neisser, the discoverer of the gonococcus, especially with reference to the powerful antibacterial properties of Protargol.

PROTARGOL has been used with the greatest success in ocular therapeutics (blepharitis, dacryocystitis, etc.), in solutions of 5 to 20 per cent.; and recently in Rhino-Laryngology (brushing with solutions of 5 to 10 per cent.).

PROTARGOL has also been highly recommended as a prophylactic for gonorrhœa (Instillations of a trituration of 20 parts of Protargol, with 10 per cent. of glycerine, mixed with 70 parts of water).

ASPIRIN.

(Acetic Ether of Salicylic Acid.)

A perfect substitute for Salicylic Acid and its salts. It does not irritate the mucous membrane of the stomach. In consequence of its slow tendency to decompose it passes through the stomach unchanged, being split up into component parts only in the intestinal alkaline fluids. It does not cause any disturbances of the stomach or loss of appetite. Moreover, it possesses an agreeable slightly acid taste, which favourably contrasts with the repugnant sweet taste of the Salicylates. Aspirin causes none of the unpleasant after effects which so frequently attend the use of Salicylic Acid and its salts.

Extensive clinical trials have proved that Aspirin is equally effective as a therapeutic agent with Salicylic Acid and its salts, whilst it possesses at the same time the great advantage of having absolutely none of the drawbacks which prohibit at times the use of the latter.

TRIONAL, IODOTHYRINE, TANNOPINE, SALOPHEN, LYCETOL, CREOSOTAL, DUOTAL, HEROIN, PROTARGOL, ARISTOL, EUROPHEN, TETRONAL, ANALGEN, LOSOPHAN, IRON SOMATOSE, MILK SOMATOSE, PHENACETINE-BAYER, SULFONAL-BAYER, PIPERAZINE-BAYER, SALOL-BAYER.

Samples and Literature willingly supplied on application to the Wholesale Depot for all BAYER'S Specialities.

DR. J. COLLIS BROWNE'S CHLORODYNE THE ORIGINAL AND ONLY GENUINE.

From SYMES & Co., Chemists, Medical Hall, Simla, January 5, 1880.

To J. T. DAVENPORT, Esq., 33 Great Russell Street, Bloomsbury, London.

DEAR SIR,—Have the goodness to furnish us with your best quotations for Dr. J. Collis Browne's Chlorodyne as being large buyers, we would much prefer doing business with you direct than through the wholesale houses. We embrace this opportunity of congratulating you upon the widespread reputation this justly esteemed medicine has earned for itself, not only in Hindostan, but all over the East. As a remedy of general utility, we much question whether a better is imported into the country, and we shall be glad to hear of its finding a place in every Anglo-Indian home. The other brands, we are happy to say, are now relegated to the native bazaars, and judging from their sale, we fancy their sojourn there will be but evanescent. We could multiply instances *ad infinitum* of the extraordinary efficacy of Dr. Collis Browne's Chlorodyne in Diarrhoea and Dysentery, Spasms, Cramps, Neuralgia, the Vomiting of Pregnancy, and as general sedative, that have occurred under our personal observation during many years. In Choleraic Diarrhoea, and even in the more terrible forms of Cholera itself, we have witnessed its surprisingly controlling power. We have never used any other form of this medicine than Collis Browne's, from a firm conviction that it is decidedly the best, and also from a sense of duty we owe to the profession and the public, as we are of opinion that the substitution of any other than Collis Browne's is a deliberate breach of faith on the part of the chemist to prescriber and patient alike.

We are Sir, faithfully yours,

SYMES & CO.,

His Excellency the Viceroy's Chemists.

Sole Manufacturer, J. T. DAVENPORT.

"THE LANCET" on

VAN HOUTEN'S COCOA,

JULY 3rd, 1897.

"In a recent analysis
" which we have made, the results
" distinctly indicate the advantage of
" VAN HOUTEN'S PROCESS of manu-
" facture. Thus this Cocoa yields
" a decoction containing a maximum
" proportion of the valuable food con-
" stituents of the bean, and what is
" of more importance still, these are
" presented in a condition more easy
" of assimilation and digestion than in
" Cocoa not so prepared."

BEWLEY & DRAPER'S GINGER WINE

May be obtained of all Grocers and Wine Merchants.

Manufacturers, **BEWLEY & DRAPER, Limited, DUBLIN.**

CARLSBAD NATURAL Mineral Waters, Salt, &c.

THE WATERS FROM THE

SPRÜDEL, MÜHL and SCHLOSS Springs

are largely prescribed in cases of

CHRONIC GASTRIC CATARRH, HYPERÆMIA of the LIVER, GALL-STONES, DIABETES, RENAL CALCULI, GOUT, DISEASES of SPLEEN, &c.

The **NATURAL SPRÜDEL SALT** is now prepared from the Mineral Water in the form of Powder ("Pulverförmig"), and contains *all the constituents* of the Sprüdel Spring. It has the great advantage in not being affected by change of temperature or exposure to the atmosphere, therefore in this form is the most reliable, and best adapted for **EXPORT**.
